

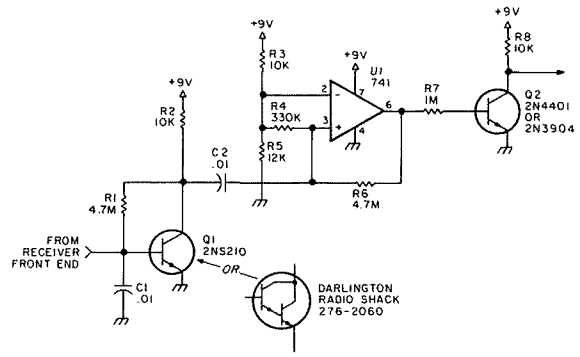

Fig. 8. The audio amp, comparator, and inverter. Use a 2N5210 if possible, or a Darlington such as Radio Shack 267-2060, an MPSA13.

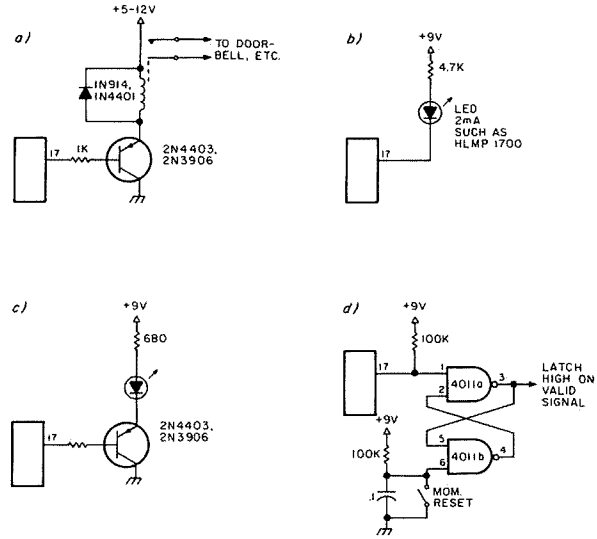

Fig. 9. Various ways to connect the decoder-chip output to the outside world. a) Driving a relay. b) Using a low-current LED. c) Using a regular LED. d) Providing a latched output. Pin 3 of the 4011 flip-flop latches high on receiving a valid radio signal.

By changing the value of L1 and C1, you can make this receiver work on just about any frequency. Now all you need is a circuit that amplifies the signal sufficiently so that the receiver chip sees nice, square 9-volt pulses.

Look at Fig. 8. The low-level audio signal is amplified by the 2N5210 transistor. This is a low-noise, high-beta (about 250–500) transistor. Use it if at all possible. You could also use two NPN units connected as a Darlington pair, or Radio Shack's 276-2060 Darlington. You should then change the base bias so that the transistor collector idles at about 4.5 volts (not critical).

Use a high-value resistor, above 500k, from Q1's base to ground to limit conduction of Q1. C1 cuts down on the amount of the high-frequency quench signal that is amplified by Q1. U1, a 741 op amp, is used as a voltage comparator and Schmitt trigger. It toggles between 9 volts and ground (almost) with a signal greater than about .3-volts input. Q2 then inverts this signal back to what it was at Q1's base.

Check and see that the Q2 collector swings less than 2 and greater than 8 volts. If it doesn't, change the value of R7 till it does. This can be verified with a scope at the collector when the receiver is receiving pulses, or by temporarily shorting pin 3 of U1 to 9 volts and ground.

Now you have a working system. Connect up the decoder chip and, with a VOM or scope, watch the normally high output pin 17 go low when it gets a valid signal. Make sure that the codes are set the same on the receiver and transmitter. If it doesn't work, look at the signal at the output of the transmitter chip. The wider pulses correspond to grounded code-selection pins 1–12. There should be very little other noise or few glitches on the received signal as the decoder chip sees it.

Output Connections

Fig. 9 shows several suggestions for connecting the outside world to the receiver. At 9(a) is the setup you'd use to replace your present garage-door receiver. Just connect the normally-open contacts of your relay across the external push-button

contacts on your door opener. At 9(b) is a low-current LED to use as a simple indicator. If you have a standard LED, use the circuit of Fig. 9(c). If you need a latched output, use 9(d). You could also have an alternate-action output (push once for on, again for off) by connecting the decoder IC output to a D or JK flip-flop. The possibilities are up to your ingenuity.

Is It Legal?

Finally, a word about the FCC. Unless you tune your remote-control system to a ham band and use it as a licensed amateur, transmitter and receiver use are controlled by Part 15 of the FCC's rules and regs. Part 15 covers all low-power, unlicensed radios and computers capable of emitting radiation into the airwaves. Ever notice that sticker on your FM radio or TV set that says it complies with Part 15? That means that the receiver emits local oscillator radiation (or any other signal) that is below limits set by Part 15, so that nobody interferes with anybody else. Ever listened to 80 meters when a nearby TV is on? It interferes with you, but at prescribed FCC limits!

Anyway, you are required by 15.133 to put a sticker on your receiver and transmitter that says:

> I have constructed this device for my own use. I have tested it and certify that it complies with the applicable regulations of FCC Rules Part 15. A copy of my measurements is in my possession and is available for inspection.
>
> (Signature)_____
> (Date)_____

Paragraph 15.133 also says that you cannot construct more than five devices of the same configuration (that means identical schematically and physically). Otherwise you need to apply for a manufacturer's registration number and submit the proper paperwork for certification of the device to the FCC. So what do you do? The units described in this article can easily be made to radiate more signal, either fundamental or harmonics, than they should. The amount of radiated signal is very small, even for the transmitter. It is something on the order of about 20 microwatts, but unless you have a 3-meter test range required by the rules, you will not have the proper equipment to test them for compliance.

Although the likelihood of the radio police descending on your house is extremely small, it is your responsibility to make sure that you do not interfere with anything else. Avoid tuning the transmitter to MHz ranges 242.8 to 243.2, 265 to 285, 328.6 to 335.4, or 404 to 406. These are forbidden areas that may cause interference to government or aircraft navigation (especially 328.6 to 335.4 near an airport). To avoid all this, tune yourself to cable channel K, which is in the 220-MHz band, or channels 57 to 61 (hyperband), which is in the 70-cm band. The possibility of interfering with any repeaters is almost nil, due to the very low power used here.

Conclusion

It is possible to make these units fit in a very small space. I used 2" x 3" board stock for the receiver and 2" x 2" for the transmitter, with room left over.

If you have problems getting your setup to work, get in touch with me. I will even fix your project in the event you can't get it going. Please include proper return postage for whatever you send. A semi-kit is also available from me for $15.00. This includes all the parts needed for one transmitter and receiver pair, less case. This kit does not include etched PC boards, but does include blank PC stock to tack-solder the components to each other.

Etched boards may become available if interest is great enough. I can also supply individual parts, such as the coding ICs and the 2N5210, etc. Contact me for price. SASE, please, for all correspondence.

If you're interested, I can also direct you to a dealer in your area who can sell you units manufactured by Linear Corporation that are tuned to 310 MHz—I can get them direct for you. The cost for a single transmitter and receiver pair should be about $45.00. ■

PAC-COMM

GIVES YOU PACKET RADIO CHOICES

PAC-COMM TNC-200

- Official TAPR TNC-2 design
- Top quality components
- Version 2 protocol
- Full duplex hardware HDLC
- Adaptable for HF packet
- 16K battery backed-up RAM
- 32K EPROM, software clock
- Multiconnect software
- Five labeled LEDs for status
- CMOS for low current drain
- NMOS for lower cost

Assembled and Tested with Ref. Manual	CMOS -	$219.95
	NMOS -	199.95
Full kit with Reference Man. and cabinet	CMOS -	169.95
	NMOS -	154.95
Full kit with Reference Man. NO cabinet	CMOS -	144.95
	NMOS -	129.95
Hard-to-find-parts kit and Assy Man.	CMOS -	84.95
	NMOS -	79.95
Bare PC board and Assy Man.		39.95
Reference manual (100 + pages)		9.95
Cabinet with end plates		29.95

Macintosh terminal software with menus, split screen, file transfers, auto routing, and more. MACPACKET / TNC200 $69.95

NEVER SAY DIE

from page 10

bers get all involved in some really inconsequential matter—but then, for some reason, there are fewer and fewer turning out for subsequent meetings. Suddenly the club drops below critical mass and it's gone. I remember one club I used to go to which had one hell of a session over what color to paint the clubhouse. I don't think the club ever really recovered.

Check with the members and see what they think is fun. I'll bet you find the part of the meeting when they're able to stand around and talk with friends is right up there on top. The feeding frenzy is another winner. In addition to the fun of eating there's more talking with the friends. But how many clubs put off the feeding until the end of the meeting? Most!

It's fun to get in someone who can give a rousing talk. Sadly, we haven't many rousers in hamdom. If you've got a ham firm in your area, you might try inviting the entrepreneur involved. In general, entrepreneurs are interesting. They're all wrapped up in what they're doing. You must have a manufacturer or seller of some kind of ham gear within commuting distance to liven up meetings. Buy him a dinner and bring in the biggest crowd you can for him.

Another potential entertainment for your club meeting (party) is a member who's a fanatic on some aspect of hamming. You've got 'em, so dig 'em out, brush off the dirt, and have 'em explain why they're a nut case over slow scan, packet radio, OSCAR, high-speed CW, or whatever insanity has pushed them over the edge. Show and tell.

I suggest you do all you can to keep your parties clean. Keep alcohol out. That's right, kill the 807s. Alcohol does different things to different people, but it has one action in common for everyone—it makes you stupider than you were before you drank. Of what value to your club are a bunch of stupefied members falling asleep? Alcohol quickly lowers the level of awareness, making some people laugh more, and some more surly. You don't need either of these to spice up a meeting. No beer.

With a growing percentage of the population angry over smoking, bar it from meetings. Get your serious addicts to make a short trip outside to smoke when they can no longer live with their nicotine withdrawal pangs. When I give talks to clubs I always ask for no smoking—and I generally get a round of applause for saying it.

Instead of having the club entertainment committee buy cheap junky doughnuts and coffee, how about getting members' XYLs involved? Get members to bring in some munchies, dips, and other dishes for the meeting? I've been to clubs doing this and the quality of the food is way above the usual supermarket Twinky crap.

Solving Problems

Once you have your club growing, you're going to be able to start dealing with local ham problems. Have you got a TVI committee yet? No ham should ever have to handle his own TVI miseries. Any TVI complaint should be tackled by the club TVI committee—first checking the ham station to make sure it's clean. Next the committee should visit the complainer, give him a printed form explaining the whole situation in lay terms, and then attempt to get past the accrued anger to work toward a solution. Has your club a printed information sheet explaining TVI? Let me see it so I can publish some of the better ones to help other clubs. Heck, if there's a demand, I'll even get my print shop to print some up which can be bought in bulk.

The next thing you need is a committee to tackle repeater problems. If there is a statewide repeater alliance, fine, get one or two delegates from your club to attend their meetings. Even if your club doesn't have a repeater, which is unlikely these days, your club still has a strong vested interest in local repeaters being operated well.

Your club also should be in touch with the local repeater coordinating group and make sure they know you're watching them. If they start screwing up, call 'em in to explain at your next meeting. The repeater alliances and coordinating committees are only as strong as the clubs which support them.

It has not been satisfactorily determined as yet as to whether people become hams because they are crazy or whether hamming makes people crazy. We do know that, with the sole exceptions of you and me, all hams are crazy. On this premise, you shouldn't be surprised at anything which happens in amateur radio. The trick is to gear your club to cope with this craziness—with both the copers and copees being accepted as crazy.

My suggestion is this: Just as you have a TVI committee to cope with irate television owners—or hi-fi, hearing aids, etc.—you should put together a small A-Team to tackle local repeater jammers and other such trouble-makers. I like the A-Team concept—a small group of dedicated individuals, all with sneaky brains aiming at outsmarting the bad guys, but with no bloodshed. Have you ever noticed that the A-Team can shoot from the hip with a machine gun from a bouncing van at night and shoot a rope in half at a hundred yards with the first round, yet not in several years and hundreds of thousands of rounds have they ever been able to hit a bad guy? I don't think they've even winged anyone! So get your A-Teams going and make sure they don't aim for the kneecaps (like I might). Hey, I'm talking figuratively, in case there are any old farts who suddenly want to take me seriously in order to righteously put me down. I already mentioned how many nut cases we have in our blessed hobby—except, as I said, for me and thee—and I'm not entirely sure about thee.

The ham who is so determined on screwing up amateur radio for the rest of us that he ignores the first visit or two from your A-Team will call for strategy. Perhaps a mass visit from the entire club, with or without flaming faggots and pitchforks? Bring plenty of marshmallows in case the house burns by accident from a flying spark. Figuratively speaking again, of course (heh, heh, heh).

Self-Policing

The A-Team approach via local clubs will help a good deal to clean up our act. We do have to be wary of officious self-appointed police. They can cause more problems than they solve. The ARRL had a good idea with their Official Observers, but all too often OOs got carried away with their work and went overboard. I think we need something along that line—hams with the time and patience to act more like corner crossing guards than police. A polite reminder that someone is operating in the wrong subband. A suggestion that the mike gain or the compression be turned down to where the voice can be deciphered. A plea to well-known DXers not to jam the weak DX station once they've contacted it so as to keep others from getting the country. These are all delicate matters, calling for tact rather than the often used verbal rubber hose.

There are far more good guys in amateur radio than bad, so if the good guys use the strength of working together, they (we) will prevail. By the way, the bad guys know who they are. They are defensive about it, but they know they are the bad guys. Most of them are emotional basket cases that use being bad as a way of getting attention—like a bad child. We don't have the resources to put these jerks under psychiatric care, where they belong, so we just have to learn patience and deal with them one by one.

The Future

As we are able to bring our clubs up to strength—with representatives from each working with the area repeater councils—the next step is for us to get going with a national meeting every two years, with two delegates representing each ham club, to discuss and vote on needed rule changes.

As with the Geneva ITU meetings, this group should first break into working committees to discuss each proposed change. The committees would then report their decisions to the group as a whole—the plenipotentiary—for their vote. This vote would be binding and automatically enacted by the FCC. I've discussed this with the FCC commissioners and found them enthusiastic.

This would have many benefits for us—and the FCC. It would save us years in making our rules reflect the state of the art. In the past, virtually without exception, we amateurs have done our best with a minimum of rules. But we've always had a nut case or two who flatly insisted on getting the FCC into the act. I don't think anyone can remember a time when the resulting rules were needed or appropriate. I've always advised experimenters and pioneers not to ask the FCC when there is any question. If something is not specifically prohibited, then it is permitted, so go ahead and do it. Asking a government bureau-

crat to go out on a limb by authorizing something which has not previously been specifically authorized is incredibly dumb. The easiest answer is no, so that's what you get. Don't ask.

Getting our clubs involved with proposed rule changes will help develop more interest in the clubs and amateur radio. It'll give club newsletters a lot more to cover—and perhaps even make ham magazines more interesting. Right now a very small vocal minority has an outsized effect on our rules.

Executive Summary

So there you have it—the FCC hasn't the time or the money to deal with amateur radio. We need to take responsibility for ourselves. Remember, with Gramm-Rudman, it isn't going to be the 70% of the budget for entitlement payments which is going to get cut, it's going to be government bureaus like the FCC, so they're going to be able to do less and less for us.

It's time for amateur radio to face this situation and accept the responsibility. We've got to organize for the growth we need. We've got to build more and stronger clubs. We've got to organize for the growth we need. We've got to build more and stronger clubs. We've got to recruit and train new hams—and get older ones enthused to do more.

We don't need Big Brother for anything, so let's get moving toward cutting the umbilical cord.

TRANSMIT MUSIC—LEGALLY

Yes, at long last you can legally transmit music on the ham bands! However, before you start plugging your record player into your mike jack, you'd better read further. A lot further.

Now, all you youngsters sitting around old Doc, let me tell you why music is prohibited on the ham bands. You see, back before World War II, way back in the 1930s (yup, I was there–I'm a living monument to the past) we had two basic classes of ham licenses, Class B and Class A. To get the Class A license, the advanced radiotelephone license, you had to pass a stiff (for then) technical exam on radiotelephone technology. Whew!

The Class B ticket was pretty much like today's General license, complete with 13-wpm code. But 90% of the Class B licensees operated only CW. The Class A ticket allowed you to operate in the 75m and 20m phone bands, each 100 kc wide (kHz hadn't been invented then). AM phone, it was.

Class B could operate on 160m and 10m phone. Well, 10 was a VHF band then and almost completely unused. Experimental. So the B-ops either operated CW or hung out on 160m phone. 160 was a big band then, running from 1800–2000 kc—later expanded to 2050. We even had an almost totally unused CW band from 1715–1800.

40 was the big one. It was CW only and packed solid. Everyone used crystal control, so the practice was to call long CQs and then tune for minutes up and down the band. You could expect a call from *anywhere* in the band. It wasn't until variable frequency oscillators came along (vfo's) after the war that one tuned near one's own frequency.

DXers fought it out on 20m CW. Traffic nets and rag-chewers were on 80 CW, which ran from 3500–3900 kc. The B-ops on 160 mostly used simple homemade rigs. The most popular was a 6L6 crystal oscillator modulated by a 6L6. In the cities 160 ops would build afternoon groups rebroadcasting each other from one end of 160 to the other so everyone in the group could hear everyone else. Sure, six ops would tie up six frequencies, but heck, there weren't enough of us so it made any difference, even in New York City. We called it duplex operation. At night 160 was too crowded for this as stations from the whole East Coast would be heard.

But then, as today, no sanity exam was given, so we had as high a percentage of crazies as we do today. Some of these boneheads would get on 160m and play records all afternoon. Eventually the FCC got fed up with this crap and passed a rule which made it illegal to transmit except for the purpose of communications. This meant no one-way transmissions (except by W1AW), no blank carriers, no music, and, sadly, no more duplex.

Of course duplex today on most of the low bands would be too wasteful of frequencies. Remember, we went into World War II with only 50,000 hams. Remember, too, 40,000 of us joined the military! Without us our country would have had a lot tougher time. It was electronics which did much to win that war.

Now, getting back to a legal way to transmit music on any ham band. Have you figured it out yet? Simple, really. Just consider what's happened with digital audio. Our compact discs are merely encoded with digital data which a computer can translate as music. It's those old zeros and ones, just like any digital communication.

So, as long as you send the digital information over the air, it doesn't make any difference whether a computer translates it into words, music, or pictures.

Hold it. Don't plug your CD player into your mike jack either. Your player has a built-in decoder so you get analog out. Music. You need a CD player with a digital output—like we're starting to see for CD-ROM use. Here's one more dash of cold water: Since digital audio is sampled at 44 kHz, you're either going to have to transmit a very wide band to send it in real time or else slow it down the way we do with SSTV—so you don't take up too much bandwidth. Okay, so it could take ten hours to transfer a one-hour CD. You want to bet some damned ham somewhere doesn't do it just to prove it can be done? Probably to Africa on 20m too. Anyone want to offer an award for the first DX music transfer on 20m? Let's keep it to the "Minute Waltz," okay?

If you're interested in digital audio, guess what? I also publish (surprise) a magazine called *Digital Audio*. It's going gangbusters—devoted mostly to reviewing new CDs and CD players. It should be on your local newsstands. If you have a CD player, you really can't get along without the magazine. You see, far too many of the new CDs are disasters—and, at around $12 each, it doesn't take many bum CDs to more than make up for a subscription to *Digital Audio*. We review a hundred or so CDs in some issues.

Let me know if you try sending digital music, okay?

WESTLINK WINS ONE

Bill Pasternak WA6ITF's *Westlink Report* got the news out accurately on *73*'s move to WGE from CW Communications. Good work, Bill! The staff changes, cited as major by W5YI, were less than that, as can be seen by checking old *vs.* new *73* mastheads.

Perry Donham KW1O is back as Editor after a short stint at *inCider* Magazine. Steve Jewett KA1MPM is here, too, taking on the task of Production Editor, learning our state-of-the-art computer production system. Chris Schmidt came on board last week as Managing Editor. The rest of the staff is the same... International Editor Dick Phenix, Editorial Assistant Carole Macioci, Art Director Dianne Ritson, Designer Susan Hays, and Marketing Manager Hope Currier.

Jim Gray left, moving to *Modern Electronics*, I understand. Nancy Ciampa moved up to Sales Manager. Stu Norwood, who edited *73* several years ago, is back. Several other past *73*s staffers are also back with the magazine: Bruce Hedin, Sara Bedell, Bill Heydolph, and Tedd Cluff.

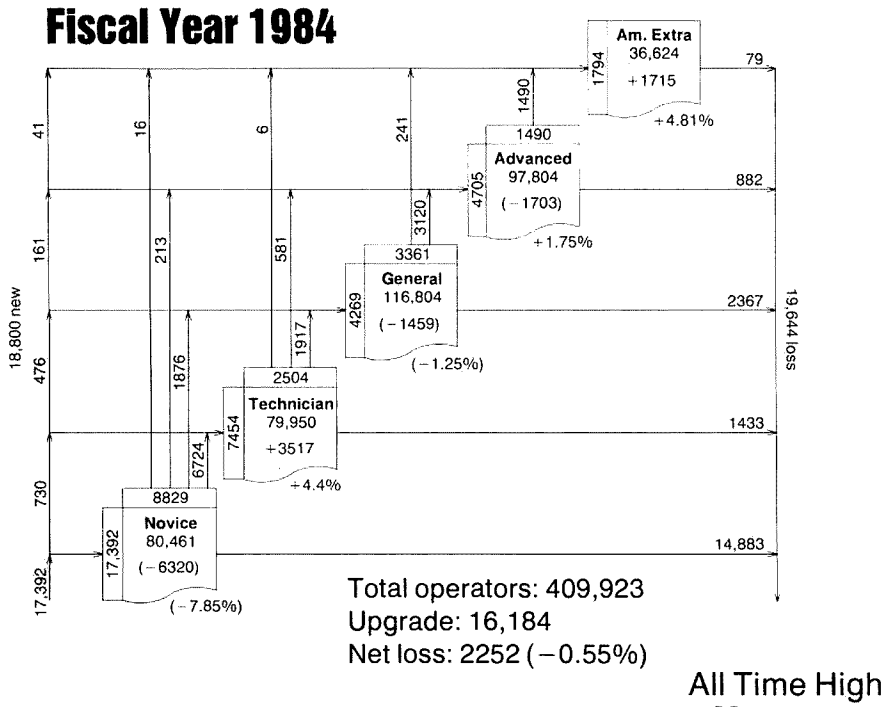
The only major change was me replacing Publisher Burnett and Executive Editor Philbrick so I will be able to give *73* the direction I think you want. Mind you, it'll take a few months to get *73* the way I think it should be, but with your help we'll not only have a fun magazine to read, but we may be able to get our hobby growing again—something it hasn't done much of for over twenty years.

It takes an enormous amount of work by a lot of people to get you *73* every month. We're all working for you—to help make amateur radio more fun for you. It's you who write the articles we publish. It's you who subscribes—and remember most of your subscription money goes to our beloved postal service. It's you who buy the ham gear and services advertised in *73*, and it's these ads which pay most of the freight. If you buy more, we are able to sell more ads and bring you a fatter magazine. If you don't buy, all you get is a lousy pamphlet. It's you who urge your friends and fellow ham club members to subscribe, thus helping *73* to grow. All I can do is sort out the articles I think you'll want to read and write editorials you'll enjoy... or hate. My basic goal in life is to educate, so you'll find my editorials make you think—and you'll find plenty of articles aimed at helping you understand our fast moving technology.

Yes, I know about those old curmudgeons who hate Wayne Green. There will always be a few people who don't want to think... don't want to learn... who hate change. They're always going to find me disturbing. But I'll bet you find them as miserable to deal with as I do... as even their family does.

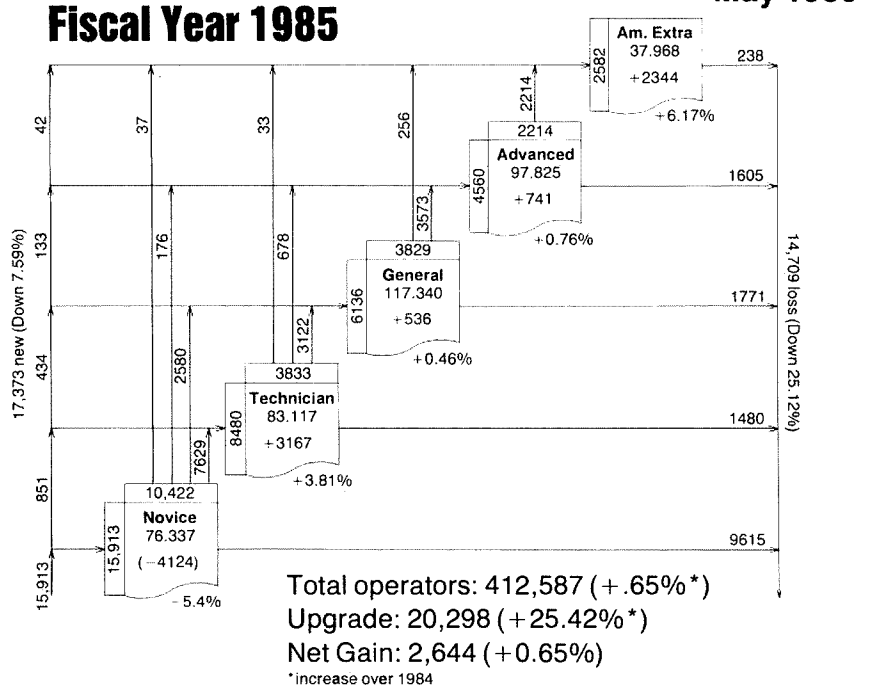
I have a psychological problem you have to deal with. So you might as well recognize it. This is my drive to get others to enjoy the

things I enjoy. Whenever I find something fun to do, I'm right out there doing my best to get others to join me in the fun. That's one of the reasons I started *Byte* magazine ten years ago. That's why I was such a nudge about FM and repeaters 17 years ago. That's one of the reasons I started *Digital Audio* magazine. That's why I'm trying to organize a yearly DXpedition. Heck, that's what got me into ham publishing in the first place, 35 years ago... and pushed SSB so hard 30 years ago.



I was having such a ball with ham Teletype that I wanted to get others to try it and see how much fun it was. You know, hundreds of thousands of people are doing almost the same thing today with the computer bulletin boards and networks. They're sitting there, hooked by the phone wires, talking with each other. If word ever leaks out that they can do the same thing for free via amateur radio, we could be inundated.

I got interested in RTTY back in 1948 and took to it immediately. I found that communications via a keyboard made for much more interesting conversations than most CW or phone contacts. It takes a little longer when you type, but it also somehow brings out a lot of a person's personality. I found many hams who were deadly bores on phone to be clever and thoughtful on RTTY. The computer network users are finding the same thing today—as are the packet radio fanatics.



Say, if you've got a C-64 computer you might want to try one of these land-line nets and see how they work. I visited the people at Playnet the other day. Their system allows people to gather in small groups—up to six usually—and talk via their C-64 computers with each other. No restraints. If you'd like to give this a try, let me know and I'll send you the operating package, complete with disks, for $20. You could do worse than get involved and start getting the others on the net interested in hamming.

Playnet uses digital phone lines instead of voice quality, so it's a lot cheaper to use than regular phone calls. Let me know how you do. Also, let me know if this doesn't push you over the edge into packet radio.

Send a $20 check or your credit card number and expiration to me and I'll get you the Playnet package pronto. You do have to have a Commodore C-64 computer.

All Time High
May 1983

Amateur statistics for FY 1984 and 1985.

THE FCC FIGURES COVER-UP

Why some ham publishers go out of their way to cover up the licensing disaster is difficult to understand. The miserable fact is that the number of new hams licensed in 1985 was down from 1984—which was down from 1983.

If you'll check the FCC licensing charts published here you'll see that the number of Novices licensed in 1985 was down 8.5%! This is even worse than the 1984 drop of 7.9%. The situation is not getting better.

The slight increase in the total number of licensed hams (0.65%) was due to a small decrease in the number of Novice dropouts—due in turn to the effect of longer licensing terms.

If you're a fan of emphasizing the shreds of good news amongst the bad, you'll see 15% more Novices upgraded than in 1984. This helped push the total number of Novices down by 5.2% (despite the decrease in Novice dropouts, which buoyed up the Novice total). The dead-end Technician class "surged" ahead by 3.9%, while the General and Advanced classes hardly changed.

It is difficult to put a good face on what's been happening. I suppose the positive way to look at it is to rejoice that QRM will continually decrease as the *QST* "Silent Keys" column gradually eats its way through the U.S. *Callbook*. We'd better start brainstorming every way we can think of to get our hobby into gear.

The activity in Japan may be enough to keep the ITU from gradually paring down the ham bands. As the U.S. activity dwindles, the Japanese are picking it up. I wish I could get someone to translate some of the articles I'm seeing in the Japanese ham magazines. They're building all sorts of great gadgets there. Their magazines are packed with construction projects and pioneering ideas. I've got some friends there; I'll see what I can do. Of course, since we're building less these days it's difficult to get parts. Maybe we can get someone to start importing parts. If you ever get to Tokyo you don't want to miss the Akihabara section, where there are hundreds of stores selling electronic parts and gadgets. It's ham heaven—swarming with thousands of Japanese youngsters shopping for parts. Maybe someone could build a mail-order parts business here if we can get youngsters back into amateur radio.

Speaking of youngsters, a survey of the ages of the newcomers last year showed that 16% were teenagers, down from the 75% we had in the 1950s. To put that into comparative terms, we used to generate about 12,500 high-tech-career youngsters a year and now we're providing about 2,200—about 18% of what we did a generation ago. 'Tain't much.

How are you doing on getting youngsters into your ham club these days? If you're having any success, how about writing the details so I can pass them on for other clubs? Also, if you have any success in convincing youngsters to learn the code, please let me know how you did that. Most kids I've met recently think the code is stupid and those who argue for it are obviously brain damaged. Maybe it's really true that rf can cause serious mental problems.

I personally used to love the code. I adored it. I grew to love it when my Morse-code tapes were selling a couple thousand a month at $5.00 each. I think I'll make a new set of tapes and fall in love all over again. So let's keep that old code test in there so I can make plenty of money with my tapes, okay?

I won't tell you which of the ham magazines is selling the worst code tapes in the world. Scientific studies have clearly shown the enormous differences in code learning methods. The worst possible way to try and learn the code is one which a certain organization has been pushing for years. I used their system and managed to take a couple years to learn the code their way. Now days many people are learning it in a day or two—some in a few hours, using the new, modern, scientifically researched system.

Hint: This is essentially the same learning system I used with the code tapes I made ten years ago. One key element is to send each character at 13 wpm, even if you only want to copy 5 wpm. That way you train your brain to recognize the sound pattern of a character just once and you don't run into the speed plateau which I suspect has kept more people from getting ham tickets than have succeeded.

A few tests have been made with people starting to learn code at 20 wpm right off the bat. The early results seem to indicate it is no more difficult to learn 20 wpm than 13 wpm—hardly takes any longer. The main problem with 5-wpm code is the temptation to set up a table in your mind and look up each character as you hear it. Dah-dih-dah-dah, hmmm, oh yes, that's a Y. You can do this up to about 10 wpm; then the speed limit for shuffling data manually in your brain is reached and you're stranded up the well-known creek which runs from the code plateau. If you start out at 13 or 20 wpm you never see the plateau and the only paddle you need is on your speed key.

Maybe the ARRL was right when they were fighting the Novice license proposal years ago—but for the wrong reasons. It may be that the 5-wpm code test has hurt amateur radio more than it's helped. The League sure hated the idea of the Novice license, though they fought it because they hadn't proposed it and they were busy trying to keep total control of the rule changes—as they had had for many years before that.

George Sterling W1AE was the FCC chairman and he was bound he was going to get amateur radio to progress, no matter how hard the ARRL's general manager Budlong fought. George prevailed, so we got our Novice- and Technician-class licenses. As a matter of fact, for several years the ARRL lost every petition they put in for rule changes—and fought every single one they didn't put in. That perhaps made up for the earlier years when the ARRL virtually wrote all the ham rules.

I remember when I became editor of *CQ* in 1955. I visited the FCC Amateur Division and was told that Budlong had been asked to never show his face there again. The ARRL's Washington counsel, Segal (no call), was just as popular there. Oh, that's enough reminiscing. But I'll bet few old-timers had any idea of what was really going on between the League and the FCC—any more than they do today. Hint: The no-code debacle put a very heavy strain on ARRL/FCC relations, as also did the VEC situation.

Vic Clark, the previous ARRL president, and I got pretty close as a result of our work together on the FCC's Long Range Planning Committee. He was almost as upset as the FCC over the no-code disaster and complained bitterly about the room-temperature IQ of some ARRL directors he had to work with.

I have confidence in David Sumner, the present general manager. No, by golly, they've done away with the general manager title and David is the executive vice president. I wonder what the difference is? Anyway, he's a nice chap and has my confidence, as does Chris Imlay, whom I worked with a few years ago when we were both on the FCC's National Industry Advisory Committee for amateur radio. Things may be looking up.

I used to know everyone at ARRL HQ very well, but as I'm sure you've read in *The W5YI Report*, things got pretty bad for a while, so just about all the old hands quit. There was even talk of an employee union. You know, it may be getting time to restructure the ARRL and bring it up to date. It hasn't changed much in the 50 years I've know it—and I've been a member for 48 years. Both the ARRL and amateur radio would benefit if the League were brought into the 80s.

Imagine what our country would be like if we were trying to run it with nothing but sixty-year-old laws. Yes, Hiram Percy Maxim, the chap who founded the League and set it up in its present form, was a genius, but the world—and amateur radio—has changed a good deal since he died fifty years ago. Percy was also an automobile and film pioneer. I wish I'd known him.

Why do I write so much about the League? Well, they're there—and they're interesting. Also, it isn't possible to write about amateur radio and *not* write about the League. It's like writing about the United States and not mentioning the government.

I often get accused of hating the League. If you run into anyone who has that impression please ask 'em where in the devil they got such a weird idea. I've never hated the ARRL. Never loved 'em either. I try to be pragmatic, taking 'em to task when they seem to be screwing up—complimenting 'em when they do something right. Somehow my compliments seem to fall on blind eyes.

You know, when I take the FCC to task I never hear anyone beefing that I hate the FCC, yet I've been on their case far more than the ARRL. I reserve the right to be sarcastic and snide about the FCC, the ARRL, lids, the QCWA, the OOTC, and any other group which I think needs a good hotfoot for some reason.

KEEP THOSE...

Attention DXers: In case you're ever looking for something to talk about when you manage to snag a ham in a rarer country, how about suggesting they send reports now and then to the *"73* International" section? There are all sorts of things we're interested in knowing. For instance, a lot of us travel, so we're interested in knowing how we can go about getting permission to operate. . . the details. If there is a local ham club we'd like to know who to contact so we might meet with them. News of any DXpeditions, even to neighboring countries, is of interest. Contests, certificates, how many active hams there are, how difficult ham gear is to get, repeaters and their frequencies, sked times for really rare countries. . . you get the picture.

We've been getting reports from 55 countries so far in the *"73* International" section—I'd prefer reports from 300 or so. No, not every month, perhaps quarterly unless there is some special news we should know about. We need to know about special DX operations early since it takes about three months for information to be set in type, printed, mailed and then be delivered.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

FLORIDA QSO PARTY

Contest Periods:
1400 to 1900 UTC May 3
0001 to 0500 UTC May 4
1500 to 2300 UTC May 4

This is the 20th annual Florida QSO Party, sponsored by *Florida Skip*. All amateurs worldwide are eligible and invited to participate. All amateur bands may be used, 160 through 2 meters. All stations will separate phone and CW logs; phone and CW are separate contests. A station may be worked once on each band on each mode. Neither crossband nor crossmode contacts will count for contest credit. Florida stations may work other Florida stations, but for contest points only. Out-of-state stations may not work each other for contest credit. Contacts made on repeaters do not count for credit.

Florida stations will be divided into two classes. Class-A stations are those operating portable or mobile on emergency power and running 100 Watts or less output inside Florida but outside of their home counties. Class-B stations are all other stations operating in Florida. Entrants may be single operator or multi-operator, and this must be indicated on the summary sheet.

Each entrant agrees to be bound by the provisions of the contest announcement, the regulations of the applicable licensing authority, and decisions of the *Florida Skip* Contest Committee, which are final.

EXCHANGE:

Florida stations send RS(T) and county of operation. Others send RS(T) and U.S. state, Canadian province/territory, or country.

FREQUENCIES:

Phone—3.945, 14.279, 21.379, and 28.579.

CW—3.555, 7.055, 14.055, 21.055, and 28.055.

SCORING:

Florida stations count one point per QSO with out-of-state or other Florida stations. Multiplier is the sum of states (49 maximum), provinces/territories (12 maximum), and DX countries (27 maximum) actually worked. Note that the maximum multiplier is 88. Florida Class-A stations only: multiply final score by 1.5 to obtain total score. Others count 2 points per QSO with each Florida station. Multiplier is the number of different Florida counties worked (67 maximum). Final score is the product QSO points and the multiplier.

AWARDS:

Certificates for phone and CW to the top single-operator score in each state, province, territory, DX country, and each Florida county. Multi-operator winners will receive certificates as activity justifies. There are also 5 plaques to be awarded as follows: high single operator in Florida and out-of-state, CW and phone; and to the Florida club with the highest aggregate score. There is no minimum number of contacts to be eligible for a certificate.

ENTRIES:

Phone and CW entries are to be separated! Along with legible logs in chronological order, a summary sheet is required with each entry. Those with 200 QSOs or more must supply a dupe sheet. The summary sheet must contain claimed score, Florida county or state operated from, number of QSOs, multiplier total, station callsign, entry class, and power source for Class-A entries. The name of the Florida club for which aggregate total credit is being assigned must also be on the summary sheet. A signed declaration that rules and regulations have been observed must also be included. Sample summary and log sheets are available for an SASE from the QTH below.

At the discretion of the contest committee, stations and/or operators may be disqualified for improper reporting, excessive dupes, errors in multiplier lists, unreadable logs, obvious cheating, etc. All entries must be received on or before June 6. Mail all entries to: *Florida Skip* Contest Committee, North Florida Amateur Radio Society, PO Box 9673, Jacksonville FL 32208.

ARRL VHF/UHF SPRING SPRINTS

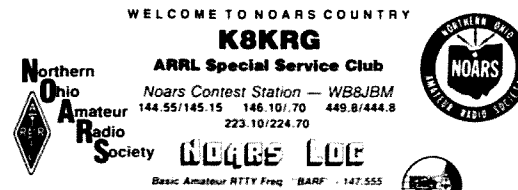
May 8—1296 MHz
May 17—50 MHz

Each sprint runs from 7 p.m. to 11 p.m. local time. These contests are sponsored by the ARRL; each is a separate event and are single operator only.

Retransmitting either or both stations or use of repeater frequencies is not permitted. Only recognized simplex frequencies may be used. Contest entrants may not transmit on repeaters or repeater frequencies for the purpose of soliciting contacts. Use of the national calling frequencies is also prohibited.

Stations are allowed only one transmitted signal at any given time. A transmitter used to contact one or more stations may not be used subsequently under any other callsign during the contest—except for family stations for which more than callsign is assigned to one location by FCC, DOC, etc.

EXCHANGE:



Grid-square locators (see January, 1983, *QST*, page 49); signal reports are optional.

SCORING:

Count one point per valid QSO and multiply QSO points by the

Nov 15–16	ARRL Sweepstakes—Phone
Dec 5–7	ARRL 160-Meter Contest
Dec 13–14	ARRL 10-Meter Contest

NEWSLETTER OF THE MONTH

One of the most consistently excellent newsletters we've seen over the past few years is the *NOARS Log*, journal of the Northern Ohio Amateur Radio Society.

NOARS is a large club with a high level of participation, and the pages of the Log chronicle the varied activities of the members in an easy-to-read style. Each issue is packed with useful information, making the Log almost a monthly reference manual!

Congratulations to Editor Bill Heitzenrater N8DSG and NOARS President George Morningstar W8ANM for their model publication.

To enter your newsletter in *73*'s Newsletter of the Month Contest, send it to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: Newsletter of the Month.

number of different grid squares worked for final score. For a valid QSO to occur, callsigns and grid-square locators must be exchanged and acknowledged. A station may be worked for credit only once per band regardless of mode. Crossband QSOs do not count.

ENTRIES:

Entries for each contest must be postmarked by June 20th. Remember, each contest is separate; use separate envelopes for each contest. Submit separate log and summary sheets for each contest entered. Logs must indicate time, callsign, and complete exchange for each valid QSO. Multipliers must be clearly marked in the log. Include dupe sheets with entries of more than 100 QSOs. Use the official entry forms, available from ARRL HQ for an SASE.

Each entrant agrees to be bound by the provisions as well as the intent of the published rules, the regulations of his or her licensing authority, and the decisions of the ARRL Awards Committee. Usual disqualification rules apply. See *QST* for any last-minute rule changes. All entries and form requests should be addressed to ARRL, 225 Main Street, Newington CT 06111.

MICHIGAN QSO PARTY
Contest Periods:
1800 UTC May 17
to 0300 UTC May 18
1100 UTC May 18
to 0200 UTC May 19

This year's QSO party will be sponsored by the Oak Park ARC. Phone and CW are combined into one contest. Michigan stations can work Michigan counties for multipliers. A station may be contacted once on each band/mode. Portable/mobiles may be counted as new contacts each time they change counties.

EXCHANGE:

RS(T), QSO number, QTH as state, Michigan county, or country.

FREQUENCIES:

Phone—1.815, 3.905, 7.280, 14.280, 21.380, and 28.580

CW—1.810, 3.540, 3.725, 7.035, 7.125, 14.035, 21.035, 21.125, 28.035, and 28.125

VHF—50.125, 145.025, and 146.52.

SCORING:

Multipliers are counted only once. Michigan stations score 1 point per phone QSO, 2 points per CW QSO, 5 points for each W8MB contact, and multiply QSO points by the total number of states, countries, and Michigan counties. KL7 and KH6 count as states; VE counts as a country. Maximum multiplier is 85.

Others take QSO points times the total number of Michigan counties. QSO points are 1 point per phone QSO, 2 points per CW QSO, and 5 points for each club station contact with W8MB. Maximum multiplier is 83.

VHF-only entries: same as above except multipliers per VHF band are added together for total multiplier. No repeater contacts are allowed.

AWARDS:

Plaques to Michigan entries are high multi-operator/single-transmitter score, high Michigan score, high Michigan (Upper Peninsula) score, high aggregate club score, high VHF-only (100 QSOs minimum), and high Michigan mobile. Certificates to high score in each Michigan county with a minimum of 50 QSOs. Out-of-state plaque and certificates for high score in each state and country.

ENTRIES:

A log and summary sheet is requested showing the scoring and other pertinent information, name and address in *block letters*, and a signed declaration that all rules and regulations have been observed. Michigan stations include club name for combined club score. Party contacts do not count toward the Michigan Achievement Award unless one fact about Michigan is communicated.

Members of the Michigan Week QSO Party Committee are not eligible for individual awards. Decisions of the Contest Committee are final. Results will be final on July 30th and will be mailed to all entries. Mailing deadline is July 1 to: Mark Shaw K8ED, 3810 Woodman, Troy MI 48084.

Michigan Achievement Award

This will be the 28th year that hams have had their own program to publicize Michigan and its products. Just as in past years, the governor will award Achievement Certificates to hams who take part in telling the world of Michigan's unlimited resources, opportunities, and advantages. Certificates are awarded on the following bases:

1. A Michigan ham submits log information and names and addresses (if possible) of 15 or more contacts made with out-of-state or DX hams in which information regarding Michigan was passed.

2. An out-of-state ham (including Canada) submits log information and names and addresses (if possible) of at least 5 Michigan hams who relate facts to him about Michigan.

3. A foreign ham (excluding residents of Canada) submits the call letters and name/address plus log information for at least one Michigan ham who has told him about Michigan.

Only QSOs made during Michigan Week, May 17–24, will be considered valid. All applications for certificates must be postmarked by July 1st and mailed to Governor James Blanchard, Lansing MI 48902, U.S.A.

ARI ITALIAN
INTERNATIONAL CONTEST
Starts: 1600 UTC May 17
Ends: 1600 UTC May 18

The object of this contest is for worldwide amateurs to contact Italian stations, including San Marino, Vatican City and SMOM. Use all bands 160 through 10 meters. Operator classes include: single operator CW, SSB or mixed modes, multi-operator single transmitter, and SWL. Multi-operator stations can use both CW and SSB.

EXCHANGE:

RS(T) plus QSO number starting with 001. Italian stations will send a two-letter province instead of the QSO number.

SCORING:

European stations count 2 points for each QSO with an Italian station. Others count 4 points per Italian QSO. The same station can be contacted on the same band once on CW and once on SSB.

Count one multiplier for every province per band. San Marino, SMOM, and Vatican City are additional multipliers. Final score is the sum of QSO points from all bands times the sum of the multipliers from all bands.

AWARDS:

A special award will be issued to the top 5 of every class of participation. A certificate will be awarded to the top scoring operators in each country and for each category. The WAIP (Worked All Italian Provinces) is issued to all amateurs for contacts with 60 different provinces. This will be issued upon a written application in the log, and a separate list of QSOs for the award. Only for contest QSOs, QSLs are not required. The cost to the WAIP award is 10 IRCs.

ENTRIES:

Logs must contain date/time in UTC, band, mode, call sent/received score and new multiplier. Use separate logs for each band. Include a summary sheet with your callsign, call of participation, QSO points and multipliers on each band, and final score. Usual declaration that rules of the contest has been followed is also required. Don't forget your full address, rig description, and comments.

Logs must be mailed within 40 days from the end of the contest to: Giorgio Beretta I2VXJ, Via Sciesa 24, 20135 Milano, Italy, or addressed to: Contest Manager, c/o ARI, Via Scarlatti 31, 20124 Milano, Italy. Any logs without a summary sheet and declared score will be used as a check log. A declared score of 5% more than the actual score means disqualification.

CLARA AC/DC
"MYSTERY" CONTEST
Starts: 1800 UTC May 27
Ends: 0800 UTC May 28

The contest is open to all YL and OM amateurs. Each CLARA station may be worked twice, once on CW and once on phone, or same mode on two different bands. All contacts must be made in accordance with operator and station license regulations. No net or list operations, no crossmode contacts, no 10- or 2-meter repeater contacts. Three unidentified "Mystery" stations will be operating during the contest.

EXCHANGE:

Name, serial number starting with 001, RS(T), QTH, and if a CLARA member.

FREQUENCIES:

Phone—3.755, 3.900, 14.160, 14.280, 21.300, 28.488, and 28.588.

CW—3.690, 7.035, 14.035, 21.035, and 28.035.

SCORING:

For the base score, CLARA members score 1 point per contact with nonmembers (whether OM or YL), 2 points per contact with CLARA members, and 3 points for each CW contact. Non-

members score 2 points for each CLARA contact, 3 points for CW contacts. All multiply the base score points by the number of Canadian provinces/territories worked for the total score. The contest manager will add 10 points to the base score of each log for every Mystery station contacted.

AWARDS:

CLARA members are eligible for the 1st place CLARA cup and certificate or the 2nd place certificate. Nonmembers will receive a plaque for 1st place, and certificates for 2nd place and 1st DX. All logs submitted are eligible for the mini-prize drawing as well.

ENTRIES:

Single log entry with logs showing date/time (GMT), band, mode, callsign worked, report and serial number sent, report and serial number received, name of operator of station worked, QTH, and points claimed. Logs must be signed and show full name, callsign and address of operator, and final score (points claimed not including mystery stations). Logs must be legible, no carbon copies, and no logs will be returned. Decisions of the contest manager will be final. Logs must be received by the contest manager before July 15th. Address entries to: Muriel Foisy VE7LQH, RR#1, Pender Island, BC, Canada V0N 2M0.

NATIONAL 6-METER INVITATIONAL NET (SIN) ACTIVITY DAY CONTEST
Starts: 1400 UTC May 31
Ends: 2400 UTC June 1

All 6-meter ops invited to enter.

EXCHANGE:

Call, SIN # and grid square.

SCORING:

SIN member QSOs count 3 points, non-SIN members count 2 points. Multiply grid squares by points received for total score.

ENTRIES AND AWARDS:

Certificates issued to three highest scores and one lowest score. Send contest logs by July 1st to Lisa Lowell, KA0NNO, POB 249, Ft. Lupton CO 80621.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

COPYING THE MAIL

The biggest kick I get out of doing the annual "FUN!" poll is reading the comments nearly everyone adds to their response forms. To call hams an opinionated lot would be to understate the situation!

Lack of space usually prohibits printing more than a handful of remarks at the end of the yearly results, so this time around I'd like to dedicate an entire column to our readers' view of ham radio.

In many ways, I find the comments more illuminating than the raw statistical data. The numbers tell part of the story, showing how many hams think one way or the other on a particular issue. But data don't express the human side of the hobby—the hams who feel stymied by a lack of leadership or those who fear for the hobby's future.

Next month we'll bring you the data. For now, let's take a look at the emotions.

Here's a representative sample of what you had to say:

This was lots of fun—KD8VU
That was the idea.

To say that I cannot operate in a particular range of the ham radio spectrum is, and shall always be, in my opinion, a blatant violation of my personal rights under the first amendment of the U.S. Constitution under the subheading of free speech. It could also constitute a violation of my "civil rights" as well—WA2RCB
Right. And not allowing me to drive my Corvette at 140 mph down the Long Island Expressway violates my rights, too. Ain't government something else?

What happened to the fun questions about gay nets or pocket protectors?—KA9NZI
The humor wears off after a few years. Sort of the same reason why I stopped reading QST.

The FCC puts fear in most people. I have never heard of a ham being afraid of another ham. It's 6:20 am here. I just talked to one of those do-gooder hams. . . he says I should be on the air making contacts, not writing a letter that will end up never being read!—KA9LNT
I'm afraid of W1AW, but only on October 31. Tell your buddy he's wrong.

Amateur radio must advertise if it wants younger people to join. Make ham radio known.
Were you thinking of placing ads in Modern Maturity *or* Casket and Sunnyside?

When they market a machine with the features of the Amiga, the popularity and reliability of the IBM/XT/AT, and sell it for $1,000, I'll buy it.—WB3JYF
And when they market a car with the features of a Corvette and the popularity and reliability of a Cadillac Eldorado, and sell it for $5,000, I'll drive it!

I see learning the code [as] a way to keep the CBers off the ham bands (some still get in); anyone really wanting to become a ham can study and learn the code and earn their license.—KA7PRR
I guess I'm one of those little devils who snuck in (ex-KBX-8669).

John—how about trying some questions on weak signal VHF/UHF stuff?—Anonymous
I would have, but I didn't have the energy.

I kind of resent the word amateur, but, then again, that is the only way that there can be a differential between commercial and nonprofit radio operation.—KK2W
There's nothing wrong with being an amateur, OM. An amateur is motivated by love, not mere money. A true amateur never purposely does shoddy work. Can the same be said for professionals?

I am returning to the hobby after a 30 year absence. Things have changed somewhat.—KB6HYK
Yeah, we're all a lot older.

For someone having technical interests, finding a rewarding and interesting QSO can be hard. I helped to write MCI Mail. Hope you like it. Also, contests have got to go.—KC3NG
I like MCI Mail and use it at least two or three times a week to mail manuscripts to editors. Good job. As far as contests go, let's attack 40 meters with flaming torches during SS weekend.

Plan to buy home computer soon, but not for radio use.—Anonymous
I know what you mean, computers make lousy radios. However, the old TRS-80 Model I was so badly shielded it worked fine as a transmitter.

I feel the ARRL is doing a good job in lieu of an effective FCC.—N0EON
Uh-huh. And I feel that a broken light bulb does a good job in lieu of an effective 6146B.

Contesting should be limited to certain segments of the bands.—Anonymous
Yeah, 900 GHz and up.

Don't let computers scare you. Kids will still take interest in ham radio.—KL7GID
Computers don't scare me. I make my living writing about them. It's the people selling them that make my hair (what's left of it) stand on end.

Question 50 is ghoulish and unwanted! I'm conservative and enjoy rock music. How do you categorize me?—Anonymous
Ghoulish and unwanted.

Why did you print most of the questions to this poll on the other side of [the] page. I had to flip this damn page 37 times! Bet you lost quite a few potential responders because of this.—K1DOW/4
Yeah, guess I lost all of the readers with weak arms. CW will do that to you.

Yes, I wear a pocket saver. VE program stinks. *73 Magazine* downhill without Wayne. New calls stink. ARRL detriment to amateur radio.—K3PLV
But how about an opinion?

Be sure ARRL gets a copy of your final numbers.—K4YTB
I think they have a subscription.

I think the students at Junior High School #22 should stop begging for equipment.—K7ERN
Do you know how much money the NYC Board of Education spends on ham radio? Close your eyes and you'll have a rough estimate. Instead of griping, you should send your unwanted gear to WB2JKJ or to your local school. Make an investment in our future.

I think the last two questions are slightly unfair. If I heard an emergency net in progress, I would listen first to determine if I could be of help or would hinder the operating. As a member of ARES I get plenty of opportunity to offer my "skills" for community service.—KC7NA
Slightly unfair, but FUN!, right?

Could you send results—prepublication—of this annual event?—WA2OVG
That would be cheating, Hank. How much will you pay me?

Will be interested in seeing your tabulation.—K0GP
Next month, OM

NK6K > PACKET

Harold Price NK6K
1211 Ford Ave.
Redondo Beach CA 90278

Starting with this issue, 73 is proud to add Harold Price NK6K to our growing list of specialists.

Harold has been active in the field of amateur packet radio since early 1982. Starting with home-brew hardware, software, and protocols, he switched over to the AX.25 protocol when it was first announced as a standard in October 1982. He was one half of the first on-the-air two-way contact using the AX.25 protocol. He was also part of the three-person team that developed the software used on the TAPR TNC-1.

He was part of the early packet experiments on the OSCAR-10 spacecraft. He worked on the US/Canada hardware and software team that supplied the Digital Communications Experiment for the UoSAT-OSCAR 11 spacecraft. He assisted in final launch preparations and has continued to develop new software for the orbiting spacecraft. He is project manager for the PACSAT satellite.

Harold has authored many articles on amateur packet radio, including several that were published in non-amateur magazines. He is a regular speaker at both local and national amateur gatherings, as well as at non-ham conventions and meetings for the IEEE, computer shows, and the broadcasting industry. He is active in southern California band-planning efforts and in local packet activities.

Harold is on the board of directors of TAPR and AMSAT, and serves on the ARRL Ad Hoc Digital Communications Committee. Professionally, Harold is a computer and communications consultant.—Ed.

Welcome to the new packet-radio column! Before we start, I'd like to try something, so please bear with me.

I don't always agree with Wayne Green. The ARRL has done a lot to further the development of packet radio.

If there were fewer than two sentences in the above paragraph, then you'll know that Perry Donham was less than honest when he talked me into doing this column. In fact, if this whole introduction is missing, you'll know he fudged on the additional promise that I could be irreverent!

While we're on the subject of honesty, I should say that I live in that great non-federally-funded anthropological and sociological experiment called southern California. Therefore, any warped views should be regarded as environmental and not hereditary, so don't blame my Dad N3ECV.

Next, this column is a "conducted column," not a "written" one. That means this is a participatory venture—you are requested to write to me with news, thoughts, comments, and gripes. Only write if you agree with me, though; if you want to disagree with someone, write to Wayne.

That said, let's get to it. The subject is packet radio and other high-speed digital communications techniques. As of this writing I'm a member of three bodies that should interest you if you're interested in packet radio. I'm on the board of directors of the Tucson Amateur Radio Corporation (TAPR), the board of directors of the Radio Amateur Satellite Corporation (AMSAT), and I'm a member of the ARRL Ad Hoc Digital Communications committee. That means I'm in a position to hear some interesting things about what's going on in packet, things that I'll pass on to you. It also means that I can pass your thoughts on packet to the decision makers of the organizations that are actively involved in the development of packet radio. Even if you disagree with me, I'll pass your comments on... grudgingly.

Terms

You'll find that the term "packet" is in danger of becoming a generic term for any high-speed amateur digital communications technique. It is actually only a subset of the possibilities. Packet is a technique of breaking information down into small pieces, appropriately called "packets." The act of passing these pieces around in interesting ways is called "packet switching." There are other ways to pass information around in digital form, but few if any have been implemented on amateur radio yet. Hopefully, the next few years will see digital voice, digital video, and other high-speed digital forms of communications come into use. This column will "limit" itself to digital communications, excluding CW, RTTY, and AMTOR, as these three modes are adequately covered elsewhere.

Packet Introduction

I don't have much room left over this month to give a full introduction to packet radio. Besides, that could be a little dull, so we'll do the training a little bit each month. In case you've never heard about packet before, here's a real short introduction:

Packet is a method of sending information over amateur radio, just as spark, CW, AM, SSB, FM, RTTY, AMTOR, SSTV, and FSTV have done down through the years, but with two major differences. Packet provides for "perfect" information transfer, and it permits multiple simultaneous contacts on the same frequency. It is "perfect" because packet uses computers and a complex method to check each piece of information to see if it was received correctly. Packet procedures ensure that a packet is retransmitted until it is received correctly. Packet can share a frequency because information from any one station is broken into small pieces. These pieces can then be mixed in with pieces from other stations on a single frequency. Because each packet is tagged with the callsigns of the sending and receiving stations, each station can keep track of which packets are for it.

The device used to "do" packet radio is called a Terminal Node Controller (TNC). This is a small interface box that goes between your radio and your terminal or computer. The microprocessor inside the TNC takes care of following all the procedures necessary to exchange data with other stations. To learn more about packet, check back in your stacks of magazines for, or borrow from a friend, the following:

Price, H., "What's This Racket About Packet" and "A Closer Look at Packet Radio," *OST*, July and August, 1985.

Johnson, L., "Join the Packet Radio Revolution," *73*, September and October, 1983, and January, 1984.

These articles contain pointers to other information sources on packet. Most larger radio stores will have a TNC on display or even operating on the air. The most common frequency in use for packet radio in North America is 145.01 MHz. We'll do a little more on packet introductory material here next month.

Packet History

Following is a capsule history of some of the aspects of packet-radio development. I have previously placed an earlier version of this history on public BBS systems, so you may have seen some of this before. But for newcomers to packet, here is the answer to the question, "How long has amateur packet radio been around?"

•September 1978: Non-baudot digital transmissions made legal in Canada. Digital experimentation begins.

•January 1979: Vancouver Amateur Digital Communications Group (VADCG) formed. This group produced the VADCG TNC, some of which are still in use today.

•Summer 1979: Work begins in Ottawa and Montreal. Total North American digital users = less than 30.

•March 1980: ASCII data legalized in the United States. Canadian missionaries armed with VADCG TNCs and software cross the border.

•December 1980: First United States digipeater goes on the air in San Francisco. It used home-brew hardware and software based on the VADCG protocol (now called V1).

•1981: First great packet diaspora begins. VADCG distributes PC boards. Home-brew systems are developed. Most areas standardize on 1200-baud Bell 202 modems, VADCG-compatible hardware, and 2-meter FM. Locally maintained software versions in San Francisco, Washington DC, Vancouver, and elsewhere begin to diverge.

•October 1982: AMSAT and AMRAD host another in a series of meetings to solve the divergence problem by developing a protocol standard. Other major goals include the desire to support more than the 32, 64, or 128 users allowed by then-current V1 implementations. The AX.25 standard is born. Total North American digital users = less than 200.

•January 1983: After several months of design and testing, the Tucson Amateur Packet Radio (TAPR) group produces 170 assembled and tested beta-test TNCs.

•October 1983: The kit version

of the TAPR TNC (now called TNC-1) is tested by 19 users.

•December 1983: 200 TNC-1 kits are shipped. In the meantime, more VADCG boards are assembled. GLB takes out its first ad in *QST* for an assembled and tested unit. Total TNCs = about 650.

•1984: TAPR begins to ship TNC-1 kits in bulk. They ship an average of 120 TNCs per month for the next 15 months. AEA announces an assembled TAPR TNC-1 clone at the Dayton Hamvention. Packet hits the big time when Lyle Johnson WA7GXD wins the Dayton Hamvention Technical Excellence Award for the TAPR TNC. He accepts on behalf of packet radio and TAPR. AEA legitimizes packet by placing the first full-page ads for packet equipment in the big ham magazines. At the end of 1984 there are more than 2500 TNCs.

•1985: Heath announces the HD-4040 TNC-1 clone kit, begins shipping in April, and sells out the first 500 in three weeks. Kantronics announces the "Packet Communicator." TAPR announces TNC-2. GLB announces PK1L. AEA announces PK-64 and PK-80. For a time in August, most of the packet industry is "sold out," with demand far exceeding production. Bulletin board systems running software designed by W0RLI begin to proliferate. "RLI" systems allow for the automatic exchange of messages between them. Messages, routed by the BBS systems, crisscross North America on a combination of HF, VHF, and UHF frequencies. Ties between the National Traffic System (NTS) and packet networks become more common. There are at least 10,000 TNCs in the field, worldwide.

•January 1986: More TNCs and TNC add-on products are announced. AEA announces an HF modem that can be added to any TNC. When an amateur group in Ester, Alaska, produces a VHF/HF mode switch for TNC-1 and TNC-2 style modems, they give their street name as "AX.25 Communications Trail." It is predicted that more than 14,000 TNCs will be in the field by March. The number of amateurs working on improvements to existing packet networks and developing new directions for the future is also increasing. A group in Hamilton, Ontario, is making an IBM PC plug-in board available. A Texas group is working on a network linking system, as is a group in Florida. TAPR is working on networking hardware and software. Networking software from New Jersey will be available soon.

1986 will see the launch of two satellites with packet radio facilities on board, Japan's JAS-1 and the international AMSAT Phase III-C. The UK's UoSat-OSCAR 11 satellite, with its American-Canadian digital store-and-forward message system, has already been tested as an international information transfer device and will see greater use in 1986. This column solicits information on these and other items for discussion in the coming months.

Prove It, Packet

In closing, I'd like to answer a letter that was printed in the December, 1985, issue of *73*, page 69, under the headline, "Prove It, Packet." It seems that the letter writer went to a hamfest where an over-zealous speaker claimed that packet would replace CW/RTTY/AMTOR. I agree with the writer when he says this won't happen. The only modulation mode that ever disappeared in amateur radio was spark gap, and you can still get a demonstration of that at many hamfests.

Thereafter, the writer and I part ways. First, he refused to believe another packet proponent at the hamfest who said packet interface units would cost less than $200 by the end of the year. Through the magic of publishing lead time, the very same issue of *73* contained several ads for packet gear that carried a list price of between $209 and $219, and retailed for just below $200. GLB announced a unit that you can almost fit in a shirt pocket, and AEA had one that does CW/RTTY/AMTOR/ASCII as well as packet for the same price.

Next, the writer doubted that packet is error-free. Well, he *can* argue the point, but Andrew S. Tanenbaum, in *Computer Networks* (Prentice-Hall, 1981), says about the same error-detection scheme used by the AX.25 packet protocol: "[it] catches all single- and double-bit errors, all errors with an odd number of bits, all burst errors of length 16 or less, 99.997% of 17-bit error bursts, and 99.998% of 18-bit and longer bursts."

Less easy-to-quantify factors in the protocol, having to do with the callsign fields, control fields, and flags, comprise a large portion of the 0.002 percent of errors that slip by. You must also compute the probability that 17 or more bits will be bad in any given packet. Then multiply all the probabilities together. The chances are less than one in a million that you will get an undetected error. As a rough guess, you would have to send 128 million characters before you stood a small chance of seeing an undetected error. Since even Ivory Soap is only 99.44 percent pure, this is close enough to error-free for most people. The reason packet data arrives error-free is that packets with detected errors are retransmitted until they are received correctly.

Packet bandwidth is discussed, but that's a subject for an entire column. The writer then mentions the transmitter keying rate. Actually, packet is efficient in terms of toggles per information passed. Packet will switch once per 80 or so characters passed in a conversational mode, or once per 400 characters when moving large files. AMTOR switches once every three characters. Full break-in CW, depending on the settings and operator habits, can switch once per word, or once per character.

Finally, the writer asks why, if only 200 Watts eirp are required to access OSCAR 10, do you always see photos of 25-foot dishes or stacked 12 over 12 arrays. Because the guys with the metal in the air like to take photos of it, that's why. Those of us with just the 10-dB-gain yagi never get around to taking the pics. I put 100 Watts into 3 dB of cable loss and a poorly made N connector, then into an 11-dBi-gain antenna. I then crank the power back until I'm no louder than the beacon.

Aside from the OSCAR 10 comment, "Prove It, Packet" is a victim of rapidly advancing technology. We've come a long way in a short time, and we've hardly gotten started. Because things have a habit of changing very rapidly, to help you keep things straight I'll include the date that I finished each column somewhere in the column. This one, for example, is 2/24/86.

Please help make this column worth the space it's taking by sending in your questions and comments. I can also be reached on CompuServe at 71635,1174, and on packet by NK6K @ KD6SQ. Next month, more stuff like this, only different.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Oh boy, if only you could see this! On my desk is a stack of letters from you all. Some of them have received a response in the mail, some have not, but none of them have yet reached print. So, blessed by the wonders of my word processor, which has the ability to move whole paragraphs at the touch of a single key, let's mush through this stack together.

CoCo

I hope that Lloyd Chapman W8WHA of Toledo, Ohio, is enjoying the new CoCo keyboard he got after the tip in this column. It should slip right into the CoCo II, and there are several programs around to help use the "extra" keys. One was mentioned here a few months back.

William E. Mangor VE3BOQ of Morrisburg, Ontario, relates that the quick CoCo RTTY output program in the March, 1985, "RTTY Loop" column works fine, with one problem. The CoCo printer routine assumes that the printer adds a line feed after each carriage return, whereas the teleprinter requires that a line feed be sent. He wants to know how to do this using software. Well, the "down arrow" key on the CoCo will send a line feed, but that will only help a tad. Best bet would be to put in a machine-language filter to add a line-feed character after each carriage return. I would rather not fill these columns with listings unless there is some demand for it. So let me know, and I'll be glad to print a suggestion if a bunch of you need it.

Jay Sarajian WB3BKW in Feasterville, Pennsylvania, enjoyed the patch for Clay Abrams' NEWRTYCW program published here a few months ago. He said he had to save it as "PATCH/BAS" though, instead of "PATCH.BAS"

as titled here. I don't know why, Jay, as I normally use the period rather than the slash routinely for CoCo extensions. Not only that, but (CoCo'ers take note) you can also preface the drive number (*i.e.* 1:PATCH.BAS) rather than suffix it (PATCH.BAS:1). At least you can do this with standard Radio Shack DOS version 1.0 or 1.1. If you are using ADOS it should work as well, but if you are using JDOS all bets are off, as many of the pointers and routines have been customized. Would be interested to hear the follow-up, Jay.

Jim Leischner KA9RGJ in Cisco, Illinois, is another CoCo user who is hard at work to put his computer onto RTTY. I hope the material I sent you helped, Jim. I think you will find that the CoCo is a flexible computer that will be able to do just what you want.

Same thoughts go out to Bob Hartley K2QJ of Kendall Park, New Jersey, who is also looking to put his CoCo onto RTTY. As I have indicated, Bob, the Abrams program is the only one I have seen, but that doesn't mean that there won't be something else soon. Just keep reading, right here!

Teleprinters

Carl Anderson WA6CMT of Santa Ana, California, counts himself as one of the "silent" readership who has flirted with the RTTY bug for a long time, and now hopes to interconnect a Model 32 and/or Model 33 Teletype® with his ham gear. Well, Carl, I hope that the material presented here last month helped your efforts. Let me know how it goes!

Using an Info-Tech interface, Joe Kovarik, Jr. KD9G in La Grange Park, Illinois, is looking to hook up his Model 33 as well. Again, I hope the information from last month helps, Joe. With a Model 15 on the Murray/Baudot port and a Model 33 on the ASCII port of that interface you'll have quite a station!

Not everybody is working on Model 33s, though. Mark Hines KA8TNT of Ludlow Falls, Ohio, acquired a receive-only Model 28 and would like to interface that machine on RTTY. Assuming you have loop connections, Mark, this should be trivial. Hook into the TTY loop, send it some five-level goodies, and see what prints.

C-64/VIC-20

Interest in alternative means of interfacing the Commodore 64 computer remains high, as evidenced by the note received from George Tubb W5HI in Los Alamos, New Mexico. George is looking for, among other things, interfacing other than that provided by the likes of Kantronics, MFJ, AEA, Microlog, and others mentioned here in the past. Hmm . . . sounds like a tall order to me! I print what I get, George. I know I've said this before, but if I have not written about an item, it is not because of bias, it's because I have no information to write about. Manufacturers, are you listening? Stay tuned for Chapter Two, George!

George "Keoki" Susterich KH6DXO in Hanapepe, Hawaii, is also looking to put his C-64 onto RTTY. I have sent him the ever-growing list of "RTTY Loop" reprints available, and hope that the information printed here lately helps him connect one of the teleprinters he has to the C-64 for use as a system printer.

A VIC-20 user, Michael V. Hoffman N7GLO in Eugene, Oregon, is busy building the one-chip demodulator we talked about here a few months ago. He is trying to look into Murray-to-ASCII code conversion himself. Well, Michael, there are many schemes in use to convert five level to eight level and back again, and I think that a brief look through some back issues of *73* and other magazines may turn up just what you're looking for. There are certainly a number of commercial schemes, many of which I have touched upon here, and one of them may do as well.

Michael also asked a rather fundamental question that I have not covered here in some time, so I'll throw it in now for good measure. He said that in "thinking about AFSK and SSB rigs, . . . it seems to me that what you get from AFSK modulation of SSB is the same as you get with FSK. Can you tell them apart?" No, you can't, Michael, and that is just the point. After all, if you sent one pure tone through a SSB transmitter, what you should get, assuming that the carrier is well suppressed and there are no harmonics, is one pure rf signal, offset either above or below the suppressed carrier by the absolute value of the frequency of the audio tone used to generate it. Two tones, two rf frequencies—and if you shift one tone, you get an rf signal that shifts in step and magnitude with the audio used. Now, remember this, though—the "standard" FSK convention is low space, high mark; whereas the "standard" AFSK convention is just the opposite. So if you are using an AFSK signal to generate FSK on an SSB transmitter, use *lower sideband* so that the relationship of mark and space is reversed. If this is still not clear, let me know, and I will print a few diagrams to try to straighten this whole thing out.

Apple //

Hanspeter Nafzger HB9AQZ, a Swiss amateur who says he gets hold of a copy of *73* during his extensive traveling as part of an airline crew, is having problems putting a package onto RTTY, and wonders if any of us could help. The software in question is the Radcom Plus interface and software for the Apple, and his biggest problem appears to be that when copying OSCAR-10 telemetry data, which does not use unshift-on-space, he sees rows of letters instead of figures. He is curious if anyone has experience with this software, and might have a patch or solution. If so, drop me a line here, and I will publish the answer for Hanspeter and the rest of us, too.

My understanding is that the Apple interfaces via TTL levels. So the one-chip receive circuit from July, 1985, should interface without too much problem. Arnold Bucksbaum W0WGE of Cedar Rapids, Iowa, wants to work on that circuit for his Apple. TTL is TTL, Arnold, and the 2211 scheme should hook right up. Hope to hear from you about your success.

Miscellaneous Mishegas

Richard Keusink K7VPL in Brookings, Oregon, has the distinction of having his letter lost on my desk for quite a while. Anyway, Richard is another ham having operating hitches with his AEA CP-1. It would appear that the problems being mentioned, such as the inability to load another's call without leaving the T-R mode, are just designed into the CP-1. Looks like you will have to wait for the CP-2 (hint, hint—QSL AEA?).

Richard is also looking for press signals on the HF bands. While there have been other books on the market, the Klingenfuss books mentioned here remain the most complete one seen. Complete to the tune of overkill, in fact! I don't know if I can publish spotted frequencies here, but if my editor would let me, I would be glad to pass along interesting locations on the HF spectrum. [Spot at will, Marc!—*ed.*]

Hope all this helps, Richard, and I'll pass along whatever else I get when I know more. (Boy, I say that a lot!)

Peter Schulz in Dorval, Quebec, notes that hams interested in putting a Timex/Sinclair ZX-81 may be able to use a program he knows as the NARP program, and corresponding interface. He knows no details about this combination, do any of you? Let me know, and I will print the information here for all the T/S users to benefit.

Peter is also interested in putting a TRS-80 Model 100 onto RTTY. Sorry, but I draw a blank on that one, Pete. Again, if anyone is using a Model 100, 200, or 600, let me know, and I will help to let the gang know.

Radio facsimile transmission is not that far afield from RTTY, and the WEFAX routines mentioned here a while back have whetted a few appetites. Brad Slocum in Sunnyvale, California, is very interested in receiving this type of information via computer. Well, Brad, I know that the WEFAX routine mentioned, which was written for the CoCo, uses features indigenous to that machine. I don't know of a version that runs on IBM PC type computers. If you have a CompuServe account, you might check on the CoCo SIG (GO COCO) for the WEFAX program and related data.

Ditto to David Woolweaver K5RAV, DDS, MSD of Harlingen, Texas. David is interested in receiving WEFAX with a TRS-80 Model 4. Sorry, but I have seen nothing for that computer either for WEFAX reception. The abilities of the 6809-based CoCo really do shine in that regard.

Just what is an obsolete computer? Fred Jacob W6WBT of Davis, California, is playing with the Heathkit ET-3400 computer trainer, a 6800-based single-board computer, and wants to play with RTTY on that! Well, Fred, a few years ago I printed the source listing for both receive and transmit for the 6800 that should be easy to use on the ET-3400. They are part of the "reprint series" information that I am sending him; you can get a listing, too, for a self-addressed, stamped envelope sent to me at the above address.

Roger Wells N4AHA in Lexington, Kentucky, is interested in connecting a Heath H-89 computer to a Kantronics UTU interface. As far as I know, Roger, any terminal program should do fine, and

there are many available in the public domain. If there is a local computer BBS, I am fairly sure that a terminal program will be living there. Ask around, and don't forget the folks at your local Heath store and ham clubs. Hopefully you will be able to find a serviceable program, *gratis*, without too much trouble.

Want to get some idea of the readership of *73* and this column? Just look at where some of these letters came from: every corner of the world, it seems! I never cease to be amazed at what our buddies are doing with digital communications, and I will try to share whatever I know with you all. Let me hear from you; the letter box is looking very empty about now! As always, if you would like a reply, enclose a self-addressed, stamped envelope. CompuServe subscribers can reach me there, usually on EasyPlex, via my ppn—75036,2501. Or, if you feel lazy, just kick up your feet, and wait for the next issue of *73* to see what's in the next edition of "RTTY Loop."

ABOVE AND BEYOND

Peter H. Putman KT2B
84 Burnham Road
Morris Plains NJ 07950

Tired of sitting around the shack waiting for the band to open? Looking for more of a challenge than just picking off grid squares with your long-boom antenna and kilowatt amplifier? Need something to put the "zip" back into VHF operation?

Have I got a remedy for you! It's time to shake the dust off your feet and head for the hills—or lakes, mountains, beaches, even the local skyscraper—and go portable. Instead of waiting for the tropo duct to open to you, go chase it down for a change. If you're still waiting to work someone from that rare grid square, why not put it on the air yourself, and make a lot of other grid chasers happy! If you're tired of fighting the "big boys" with their super stations during contests, put something together on your own and give 'em a run for their money.

The Joys of Portable

You haven't lived until you've spent an entire weekend simultaneously working sporadic-E on 6 meters while swatting mosquitos, or latching into an enormous 2-meter opening while in a storm. Or perhaps you'd enjoy the simple pleasures of watching the wildlife devour your coax, as I did.

Whatever your VHF interest, there's a way to pursue it in a portable fashion. And there's certainly no shortage of equipment around to make do with, either! Throw some stuff in a backpack, bring some food and drink, and head for the hills. Somehow the effort required to go to an out-of-the-way location and work some DX makes the contact all that much more satisfying, and you might get more exercise than you've had in a long time. All it takes is the right equipment for the job and your desire to have fun. (Note the word *fun*: interpretations of fun will vary wildly depending on how kinky you are.)

The Contest Season

As you read this, the trees are bursting forth with leaves, and temperatures are slowly rising, so the weather will be on your side soon. How convenient that there are four major contests to choose from in each of the months from June to September.

First the ARRL June VHF QSO Party comes your way. About the time you start to recover from this, the July *CQ* Worldwide VHF WPX Contest shows up. Assuming you made it so far, you can dive into the the ARRL August UHF Contest. Finally, if you're still alive, the ARRL September VHF QSO Party wraps things up. Four good contests spaced just far enough apart to make you a committed portable VHFer for life (...or to have you committed for life!).

What do you need to go portable...well, how high is up? There are those who choose to carry a simple monoband battery-operated transceiver up a nearby hill for some casual operating, using a simple quagi beam. And then there are those who practically create a self-contained mobile communications support vehicle that rivals anything the military's got to operate multiband QRO stations, using enormous antenna arrays and sophisticated transceiving equipment. It all depends on how badly you've been bitten by the bug.

I've personally been involved with several portable operations, ranging from backpacking 10-Watt stations and single yagis up a mountain to operating from several camper/trailers with generator power, in temperatures ranging from 85 plus degrees all the way down to 30 degrees and below. I've been eaten alive by black flies and drenched in a downpour, nearly blown off a tower, and had masts fall on me in high winds! On the other hand, I've also seen some spectacular views of the night sky and had plenty of time to sit alone in the dark on a hilltop comtemplating nature (and my navel, tool).

If you've ever scampered up a tall building and drove repeater owners crazy kerchunking machines miles away, then you've probably got the bug and there's no stopping it. In fact, many people find FM portable operation to be eminently satisfying, and rare is the time when a ham doesn't throw an HT into a backpack or in with camping gear. FM portable is very popular in Japan and Eastern Europe as well. In fact, these folks may have refined it to an art form. One of the entries I saw from the *CQ* VHF WPX this past year was from a JA who used a Kenwood TR-50 (1 Watt, 1260 MHz FM portable) to work over 30 stations in the 23-cm band during the contest! We're still trying to get people up on 23-cm here, and he's busy firing off QSOs like there's no tomorrow.

Other entries received from Europe indicate a strong preference for this mode, with many Romanian logs indicating the use of home-brew 2-, 3-, and 5-Watt rigs to make contacts on 144 MHz FM, as did logs from Hungary. You see, FM simplex is still a novelty over there (and with all those countries to choose from and prefixes to work it's no surprise, really) so the amateurs turn out in force with their handie-talkies.

If you want to work something more exotic, then weak-signal work is the logical choice. Usually this means SSB or CW operations, and again the Europeans are heavily into it *a la* QRD.

Apparently, the Yaesu FT-290 is very popular in many countries for this type of endeavor, and for a time it was also available here as well. For some unknown reason, Yaesu has seen fit to pull it off the market, leaving us with no currently available portable 2m SSB/CW/FM equipment for the band. A companion unit for 6 meters also bit the dust, but the 432-MHz version still lives on until stock runs out or Yaesu cans it as well. All of these radios featured 1–2 Watts output from a self-contained battery-powered package with 12 memories, dual VFO's and a nice LCD to save power.

The FT-290 is particularly nice since its power level can be dropped into the milliwatt range. This would then allow the use of outboard transverters for 432, 1296, and even 50 MHz, giving you a very flexible station with four antennas and a small battery pack for the transverters—one which could be easily backpacked to a nearby hill. My advice would be to grab one if you see it at a flea market, as there isn't any other product that will do the job nicely.

You may also come across one of the time-honored ICOM IC-502/202/402 series radios. These were made for many years by ICOM and offered the user somewhat lower sophistication than the FT series, but developed 3 Watts PEP from a self-contained battery pack on SSB, CW, and sometimes FM across the 50-MHz and 432-MHz segments, and the radios had built-in collapsible whips (not very useful when working horizontally polarized stations, but a start, anyway). There are still plenty of them around and still plenty of hams using them for lightweight portable mountaintop stations. If you think you'd like a simple setup, the ICOMs are the way to go. You can always add an outboard amplifier as needed to boost the signal, and one of these and a 10-Watt "brick" will run for hours from a small storage battery.

Other than these, the selection of portable non-FM equipment has pretty much dried up. ICOM still makes the IC-505 for 50 MHz, which is a unique 3/10-Watt portable for SSB/CW/FM, using either a built-in battery pack on low power or external source on high power. For 144-MHz SSB nuts, Santec makes the LS-202 handie-talkie with SSB and FM modes built in, running 1.5 Watts output. Now *there's* a good ques-

tion: Why aren't Japanese making multimode handie-talkies? They would sure sell like hotcakes over here! How about it, guys?

Power

The next step is to get a small generator or battery and use a mobile multimode radio, preferably one with 10 Watts of power; 25-Watt types can be used if the power can be reduced to save battery life. With a generator, it doesn't matter. I've used a Kenwood TR-9000 for some time with outboard transverters for 432 and 1296 MHz to go portable on three bands with 10 Watts. A small motorcycle battery will do the trick for a moderate amount of operating. A better idea is to disconnect the final amplifier and run the TR-9000 barefoot and to throttle back on the output of the MMT transverters, as we did at Slide Mountain last year. With a good yagi, 2–3 Watts output will get you a long way. Being able to adjust the output of SSB or CW allows the ability to go to full power to make that weak contact, and to throttle back for the close-in stuff.

The whole arrangement shouldn't weigh more than 20–30 pounds, excepting your support equipment such as tent, food, clothing, lights, and so on. We overdid it for our first trip but when I do it again (and I surely will) the weight will be optimized. After all, there's no sense in bringing such things as a wattmeter if the problems it indicates can't be repaired anyway.

About the Antennas

As you go higher in frequency, remember: a given gain figure requires less metal. It's as simple as that. You can employ a lightweight PVC pipe as masting, or superlight aluminum mast sections, predrilled to slip together easily. We opted for surplus army masting in five-foot sections that were swaged, and locked together with long #8 screws. A single yagi for each band will suffice for the small portable station, and there are some beauties to choose from. One of my personal favorites is the F9FT 21-element yagi for 432 MHz. This antenna easily breaks down into four sections and can be assembled with a spintight (8mm) or wrench. It's extremely light, weighing in at about four pounds. And it's durable, using a dipole-driven element and secure through-the-boom element construction.

F9FT also makes small high-gain yagis for 1296 as well, but these need to be mounted at the top of a metal mast, as the diameter of the mast is a significant part of the wavelength in use. Of course, a PVC mast eliminates this problem. As for the lower frequencies, Cushcraft antennas are time-honored choices for mountaintopping, especially the 11-element and older 7-element versions. KLM makes nice yagis with 4, 8, and 11 elements for 144 MHz, as well as 7- and 14-element versions for 220. On 50 MHz, both companies have usable lightweight yagis around 9–10 pounds. I'm not too familiar with the F9FT 2-meter antennas, but the CueDee from Sweden also fits the lightweight requirement nicely.

The decision you make will largely depend on weight. If you've picked a good location near population centers and run a small amount of power—say, 10 or so Watts—then 7–11 elements on 144 and 220 will do the trick; 19–21 elements will make things happen on 432, and 19–23 elements will do on 1296. Keeping the elements to a minimum will reduce gain as well as size and weight, and will allow more antennas for other bands. One operation I participated in was from a fire tower in western New Jersey.

We ran 10 Watts on 144 and 432 MHz using a TR-9000 and Echo 70, respectively, feeding 11 elements on 2 meters and 16 elements on 70 cm (both KLM beams). This mast was a 20-foot slip-up, and everything was run from battery power in the 4WD truck we drove to the site. Had we brought a generator, we chould have run 10 times as much power, but we were limited to the truck battery. I'll tell you, the signal reports we got were amazing. Many multi-ops thought we were running kW stations! Of course, being at 1500 feet, 1200 feet above the average terrain, makes the difference.

As you might have expected, we got rained out halfway through the festivities, but still racked up some good Q totals with our simple equipment. There are plenty of mobile multimodes that lend themselves to this application, and many have the variable power output option, such as the ICOM 290 and 490. If you can throw a generator in the truck or car, then 100-Watt solid-state amplifiers will make will make the job somewhat easier for you.

Last but not least are the stations running large home-brew transmitters and receivers, or employing base-station multimode radios driving high-power tube amplifiers. A large number of contest portable stations in the United States operate in this fashion, and several hams have built entire kW stations for each band right into their truck or camper. One good example is Wayne Overbeck N6NB, of San Clemente, Calif., who has been a VHF nut for years and will travel thousands of miles to get on a hilltop and hand out a section or grid square. Wayne's small imported truck looks innocent enough from the outside, but the inside is loaded with sophisticated radios and amplifiers for 6, 2, 220, 432, and 1296. The Pack Rats (Mt. Airy VHF Radio Club) of Pennsylvania are noted for their well-equipped mobile stations which travel to as many as four or five grid squares during a contest to get on 1296, 2304, and higher. And of course the renowned W2SZ/1 group literally takes over Mt. Greylock each June and September for the ARRL QSO Parties, setting up stations into the 34-GHz and higher range.

So, there's no shortage of ideas when it comes to going portable. Want to try something really different? Go the the seashore instead of the mountains. You'll probably hook into a good tropo duct (especially in late July, August, and September) and work some unusual DX. This is becoming a favorite mode of contesters on the Eastern Seaboard of the United States. In fact, our group, SCORE, will more than likely make a stab at some sort of seaside portable operation for the ARRL June Contest, as there are plenty of grids that lie along the coast that could be activated. Best of all, they are all accessible by car or truck. And if you want to get R&R, it's off to the beach for a dip and maybe some sun. After all, all work and no play....

Remember also that portable operation is a big change for some hams who live in apartments or condominiums with restrictive antenna situations. There are plenty who break from "cabin fever" in January and head to the hilltops to run the January VHF Sweepstakes from their car with a multimode. Still others live in areas with high atmospheric or manmade noise levels, not to mention CATVI problems. I can relate to the latter, as our local system operator is pretty slow to fix leaks in the system on 2 meters and 220 MHz.

Unfortunately, the ARRL contests really don't give the small portable operator an incentive to make a serious run of it. This is a problem that really ought to be looked into, as it is somewhat ridiculous for a single operator with 10 Watts on 6 and 2 to be put in the same class with a high-powered multiband station on another hilltop—kind of like running the 100-yard dash against a Ferrari. On the other hand, the *CQ* VHF WPX does offer awards classes for the small guy, with QRP entries in the Single Operator, Single Band and Single Operator, Multiband categories. There is also a separate category for portable operation. Now the hilltops with their FT-290s are butting heads with each other, not some kW staton with multiple yagis.

Based on the returned logs, these classes are proving to be very popular. The U.S. winner in the portable category ran his jeep up a ravine in Nevada and nearly got in a washout, but still managed to make many contacts on 6 and 2 meters. This was also a popular class in Romania and Hungary. In fact, the top overall score in the world—F6KAW/P, with 1347 QSOs and 158 prefixes—was made by a bunch of guys running a pair of stacked F9FT beams on 144 MHz with 300 Watts of power. Imagine that—and they worked 85 grid squares in one weekend. If that isn't a good enough reason to try some portable operation, then I can't think of any others.

From the Mailbag

Ted Reinke KA7MNZ writes in with a queston about OSCAR operation that has been raised before. It pertains to operating full duplex with a single HF radio, which is of course not possible unless the radio is heavily modified. You'll still have to use two separate radios—one on 145 MHz and another on 435 MHz—to be able to hear your own signal back off the satellite. However, the setup need not be expensive if you go this route. All you need is a 10- or 25-Watt signal source and amplifier on 435, while a simple receiving converter into an HF radio or receiver will allow monitoring of the downlink. There are plenty of manufacturers of this type of con-

verter that advertise in this magazine.

Ten-Tec of Sieverville, Tennesse, makes an interesting unit called the 2510 OSCAR converter. Hooked up to your HF radio, it'll generate a 10-Watt signal on 435 MHz and listen at the appropriate downlink frequency on 145 MHz, using a dual-vfo system. Although not a duplex system, it saves the time spent looking for your downlink echo. All you need do is to locate the desired signal you'd like to work on 145-MHz SSB or CW and just start transmitting. The 435 uplink frequency will automatically be set.

Another question Ted raised is the use of a single twist antenna for both SSB and CW. It works fine, Ted! Several stations in my area have one antenna on both FM operation and weak-signal work. Of course, you'll have to use a noninductive mast, such as fiberglass or PVC, but you will certainly find the results well worth it. Add an elevation rotor and you can now listen to the downlink on 145 MHz. Add another twist for 435 and you'll work the uplink looking for your downlink on 145 MHz. Add another twist for 435 and you'll work the uplink, as well as weak-signal and FM stations on 430–440 MHz. A twist antenna isn't as good as an optimized long-boom yagi for either band, but it is an acceptable compromise. Just make sure that it is rated for the full frequency coverage of the desired bands. Both KLM and Cushcraft here in the U.S. make excellent twist antennas for this purpose.

Quite often you'll find the twist makes a difference on weak-signal work, since polarization of signals can shift over long distances and the twist overcomes some signal fading effects due to this phenomenon. I used one of these for some time locked into the RHC (right-hand circular) polarization mode, and I enjoyed many long-haul contacts on both SSB and CW, as well as simplex FM work.

Jan Kok WA4NZL writes from Charlotte, N.C., to inquire as to the availability of the Texas Instruments Dual-Gate GaAsFET mentioned in the December, 1985, column. Jan, I suggest you contact Kent Braitan WA5VJB through the *220 Notes* newsletter for more information. The device number is TI-S3030 and is very new to the market. The address for *220 Notes* is 308 Eastgate Circle, New Lenox IL 60451.

Let's hear from you! If you're into portable operation, send along some photos of your station and antennas, as well as any interesting stories. I'll provide more details of upcoming contests so you can plan ahead and get thee to a hilltop...See you "Above and Beyond!"

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards or odd-sized scraps of paper. Please type or print your request (neatly!, double-spaced, on an 8-1/2 x 11 sheet of paper and use upper- and lower-case letters where appropriate). Also, please make a 1 look like a 1 not an l—which could be an el or an eye, and so on. Hard as it may be to believe, we are not familiar with every piece of equipment ever manufactured on Earth! Thanks for your cooperation.

I need an owner's manual and schematic for the Tennelec Memoryscan–MS–2. I will pay for copies or will copy and return originals.

Terence J. Weil
1509 Victoria Street
Berkeley IL 60163

I'm looking for the following NAVSHIPS manuals: 93788 Vol. 2/3, 92175, 93241, 93210, and 91713

Charles T. Huth WB8NLM
229 Melmore Street
Tiffin OH 44883

Need one each 6SK7 and 6SG7 tubes. Will trade other items for same.

Gerald Samkofsky N4ZB
1420 Mount Vernon Drive
Holiday FL 33590

I have an R-508/ARC Command Receiver and badly need a schematic diagram of it. If you could supply one I would be glad to pay for it.

Martin Prescott
69 North Shore Road
Derry NH 03038

Wanted: Operation and/or service manuals for the Cushman CE-2B service monitor. I will pay any reasonable costs involved.

Dave Land **KD5FX**
2515 Bonnie
Ponca City OK 74601

I need any information on a computer unit labelled "C3 Data System" and "Interdata." The processing part has the identification number 7/16Jwin. The frequency meter is by Eldorado Electrodata ACL model FRO-212-2, also known as model number 1660-4, pulse generator Rutherford Elect. Co. model B7F. All items bought at a U.S. Army sale in Europe. All reasonable expenses paid.

Crispino Messina
Via di Porto, 10
50058 Signa Fi, Italy

I am compiling a list of international amateur radio nets (DX or special interest), calling frequencies, gentlemen's agreements, and so on. Details appreciated.

Ash Nallawalla ZL4LM/VK3CIT
PO Box 539
Werribee VIC 3030, Australia

I have inherited a 6-element tribander manufactured by TET. The instruction manual that accompanied the antenna is for model TE-3F36DX. Unfortunately, the dimensions in the documentation do not match the aluminum in my garage. Calls to TET and their distributor have not shed any light *on the situation.*

Does anyone have any data on 6-element TET tribanders?

Bernard M. Spiegel KJ4KR

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial offices, 73 Magazine, WGE Center, Peterborough NH 03458-1194.

WEBSTER MA
APR 27

The Eastern Connecticut Amateur Radio Association will hold the 12th annual ECARA Flea Market on April 27, from 10 a.m. to 2 p.m., at the 200 Sportsmens Club, Sutton Road, Webster MA 01570. Admission is $2; tables are $5 in advance and $7 at the door. Parking is free. For further information, contact Tom Francis KB1SP at (617)-943-7283, Dick Spahl K1SYI at (617)-943-4420, or Don Amirault K1APE at (203)-923-2727.

SIERRA VISTA AZ
MAY 2–4

The Cochise Amateur Radio Association will hold its 1986 hamfest on May 2–4 at the club's training facility on Moson Road (which intersects Route 90 five miles east of the 90/92 junction, in Sierra Vista). All ham-radio, computer, and related businesses are invited to attend. Ham exams on May 4. No charge for tailgaters; primitive overnight accommodations for RVs. Talk-in on 146.52 and 146.16/.76. For more information, contact Don Morgan W7ACI at (602)-458-5293 or write CARA at PO Box 1855, Sierra Vista AZ 85636.

FRESNO CA
MAY 2–4

The Fresno Amateur Radio Club will hold its 44th annual hamfest on May 2–4 at the Airport Holiday Inn. Inside air-conditioned dealer spaces and swap tables. FCC exams will be given; DX, emergency, and other programs; forums and demonstrations. Talk-in on 146.34/.94. For further information, contact Harry H. Billings, PO Box 783, Fresno CA 93712; (209)-268-6314.

OWEGO NY
MAY 3

The Southern Tier Amateur Radio Clubs will hold their 27th annual hamfest on Saturday, May 3, at the Treadway Inn, Owego, N.Y., beginning at 8 a.m. Flea market, vendor displays and sales, tech and nontech talks, and refreshments. A dinner at 6:30 p.m. (advance tickets only for the dinner). Take Route 17 to Exit 65. Talk-in on .22/.82, .16/.76, or 146.52 simplex. For further information, send an SASE to PO Box 7082, Endicott NY 13760.

BEMIDJI MN
MAY 3

The Bemidji ARC will sponsor a hamfest at 9 a.m. at the Bemidji Middle School on Saturday, May 3. Talk-in on 146.73. For further information, write the Bemidji ARC, PO Box 524, Bemidji MN 56601.

BATON ROUGE LA
MAY 3–4

The Baton Rouge ARC will hold its annual hamfest on May 3 and 4 at the Catholic High School on Heartstone Drive. VE Exams Saturday and Sunday at 8:30 a.m. A limited number of walk-ins will be accommodated. Send Form 610 and a check for $4.25 payable to ARRL/VEC to George Perry W5LVX, 17424 Lady Constance, Greenwell Springs LA 70739. Talk-in on 146.79/.19. For further information, send an SASE to Rick Pourciau NV5A, 879 Castle Kirk, Baton Rouge LA 70808, or call Shirl Cook K5OPL at (504)-766-0200.

GREENVILLE SC
MAY 3–4

The Blue Ridge Amateur Radio Society will sponsor the 47th annual Greenville Hamfest and Electronic Flea Market on May 3 and 4, at the American Legion Fairgrounds, one mile north of I-85 on Hwy. 25 N. VEC walk-in exams, dealer displays, indoor/outdoor flea market, packet and AMSAT demonstrations; S.C. SSB net, QCWA, ARRL, SCARDS, ARES; food, beverages, camping facilities available. Hours: 8 a.m. to 5 p.m. Saturday (early setup arrangements with advance registrations), 8 a.m.to 3 p.m. on Sunday. Admission is $3.50 in advance, $5 at the gate. Talk-in on 146.01/.61 (146.22/.82 backup). For advance registration, exam details, and further information, write the Blue Ridge ARS, Inc., PO Box 6751, Greenville SC 29606.

ROCKAWAY ARC
MAY 3–4

The Rockaway ARC will operate special-event station K2UHD from 1500 UTC on May 3 until 2100 UTC on May 4 to commemorate the 300th anniversary of the Founding of the Rockaways. Operation will be in the General (phone and CW) and Novice bands. For a certificate, send an SASE to K2UHD, Rockaway ARC, PO Box 214, Rockaway Park NY 11694.

CARMICHAEL CA
MAY 4

The North Hills ARC has moved HAMSWAP 86 to a new location at American River College, 4700 College Oak Drive, Carmichael, on Sunday, May 4, from 9 a.m. to 3 p.m. Free admission, free parking, advance table sales, food and drink available. Talk-in on K6IS repeaters: 145.19 and 224.78 MHz. For further information, write HAMSWAP 86, c/o NHRC, PO Box 41635, Sacramento CA 95841.

SANDWICH IL
MAY 4

The Kishwakee ARC will sponsor the 31st annual First-Sunday-In-May Hamfest on May 4 at the De Kalb County Fairgrounds, Suydam Road, Sandwich IL (just north of Route 34 between Routes 23 and 47, across from the airport). Admission is $2 in advance, $3 at the gate; inside display tables are $5. Outside areas for tailgating; parking is free. Overnight camping (no hookups); coffee and donuts for early birds, food wagon thereafter. Talk-in on 146.52, 444.45, and 146.13/.73. For tickets and/or further information, write to Box 21, Genoa IL 60135.

BOULDER CO
MAY 4

The Rocky Mountain VHF Society will hold its annual spring Ham Radio & Computer Swapfest on Sunday, May 4, from 9 a.m. to 3 p.m., rain or shine, at the Boulder National Guard Armory, 4750 N. Broadway, Boulder. Admission is $3 per family. Flea market, technical seminars, demonstrations, and free HT testing (spectrum analyzer, signal generator, power meter, frequency counter, and 12-volt power supply available). No extra charge for sellers; some tables available. Snack bar. Talk-in on the RMVHFS repeater, 146.16/.76 MHz. For further information, contact Dave McClune WB0ZID, 5338 Spotted Horse Trail, Boulder CO 80301; (303)-530-1872.

W. SPRINGFIELD MA
MAY 4

The Hampden County Radio Association will hold its annual flea market on Sunday, May 4 (rain or shine), from 9 a.m. to 3 p.m., at the West Springfield Elks Lodge covered pavilion on Morgan Road. Admission is $1; tables $5. There will be a $5 charge for each vehicle display. Food and refreshments available. Directions: Mass. Turnpike to W. Springfield Exit 4, 1/2 mile south on Route 5 to Abdow's Restaurant, turn right on Morgan Road; the Lodge is 3/4 mile on left. For further information, call Steve Nelson WA1EYF at (413)-596-8216.

EAST HARTFORD CT
MAY 4

The Pioneer Valley Radio Association will hold its annual flea market on May 4, at East Hartford High School (Penney High), 869 Forbes Street, from 9 a.m. to 3 p.m. (dealer setup at 8). Exams will be given by the Newington Amateur Radio League VE team; walk-ins accepted. General admission is $2; dealer tables are $8. Free parking. Talk-in on 146.19/.79. For further information or to reserve a table, contact Dave Rose KW1V, 13 Long Crossing Road, East Hamptom CT 06424; (203)-267-8993.

DEERFIELD NH
MAY 10

The Hosstraders will present their Spring Tailgate Swapfest on Saturday, May 10, at the Deerfield, N.H., Fairgrounds, benefitting the Shriners' Burns Hospitals (last year's gift: $11,754.46). Admission is $2 per person; no extra charge for tailgaters or vendors. Friday night camping at nominal fee, but no entry before 4 p.m. on Friday. Talk-in on 146.40/147.00. For a map, send an SASE to Nor-

ter Building, 735 Lafayette Rd. (State Rte. 42 S.W.), Medina, Ohio. Doors open for setup only at 6 a.m. and will be open for the public from 8 a.m. to 2 p.m. Free parking. Refreshments available. Tickets are $3.50 in advance, $4 at the door; tables are $6, flea-market space is $4. For advance reservations and tickets, write to PO Box 452, Medina OH 44258, or call (216)-725-4492 or (216)-769-3033. Talk-in on 147.63/.03 (K8TV/R).

ARMED FORCES DAY
MAY 17

The 37th annual Armed Forces Day will be recognized by Amateur Radio Station W4ODR, located Northside aboard Naval Air Station Memphis, Millington, Tenn. It will be operated by sailors and Marines from 1400Z to 2200Z on Saturday, May 17, continuously (it is hoped), as follows: SSB—7.230, 14.280, and 21.370 MHz (±10 kHz); CW—21.145 and 28.145 MHz; and 2m on 146.52 simplex. Visitors will be welcome.

Special red, white, and blue certificates will be available to those who work Whiskey Four Old

The Rhode Island FM Repeater Service, Inc., will hold its annual spring flea market and auction on Saturday, May 17, from 9 a.m. to 5 p.m., at the American Legion Fairmount Post 85, 870 River Street, Woonsocket. Admission is free; flea-market spaces are $5 each. The auction begins at noon. Talk-in on .34/.94 and .52. For more information, contact Rick Fairweather K1KYI, Box 591, Harrisville RI 02830; (401)-568-3468 from 7–9 p.m.

CADILLAC MI
MAY 17

The Wexaukee ARA will sponsor its 26th annual Swap Shop at the Wexford Civic Arena, Jct. of N. Mitchell (U.S. 131) and 13th Street, on May 17th, from 8 a.m. to 2:30 p.m. Admission is $2.50; food and refreshments available. Talk-in on WD8RZL (.97/.37). For further information, write to PO Box 163, Cadillac MI 49601.

PITTSBURG KS
MAY 17

The Pittsburg Repeater Organization, Inc., will hold its 1986

Hamfest in the Lincoln Park Pavilion, Pittsburg, on Saturday, May 17, from 10 a.m. to 8 p.m. Free tables; covered dish dinner at 6 p.m., chicken and beverage furnished by the club. Talk-in on .34/.94 or .84/.24. For further information, write Ken Johnston, PO Box 303, Pittsburg KS 66762.

SAC MUSEUM
MAY 17

The Omaha, Nebraska, AKARBEN ARC will operate station /ØEQU from 1400 UTC to 2300 UTC on May 17 from the Strategic Air Command Museum in celebration of Armed Forces Day. Operation will be in the lower 25 kHz of the 10–80-meter General bands. Send a QSL and an SASE to AKSARBEN ARC WØEQU, Box 291 D.T.S., Omaha NE 68101.

BRENHAM TX
MAY 17–18

The Brenham ARC will sponsor the Brenham Springfest on May 17–18 (10 a.m. to 6 p.m. on Saturday; 8 a.m. to 4 p.m. on Sunday) at the Washington County Fairgrounds, Brenham. Admission is free and tables are $5. Talk-in on 147.26/.86. For more information, contact J. McDermott, PO Box 162, Brenham TX 77833; (409)-289-3600 from 7 a.m. to 3 p.m. CST.

ZILWAUKEE BRIDGE
MAY 17–18

The Bay Area ARC and the Saginaw Valley ARA will operate stations K8DAC and N8GKM from 0000 UTC on May 17 through 2400 UTC on May 18 from the Zilwaukee Bridge, the only drawbridge on the U.S. Interstate system, to commemorate Michigan Week. To earn a certificate you must contact both stations. Operation will be about 20 kHz above the General and Novice splits on 20, 40, 80, and 160. Send an SASE with 44 cents postage or an IRC to SVARA/BVARC Special Event, PO Box 1783, Saginaw MI 48605-1783.

HOLY LAND, U.S.A.
MAY 17–18

The Waterbury, Conn., ARC will operate a special-event station from Holy Land, U.S.A.—a miniaturized replica of the Holy Land at the time of Christ, atop Pine Hill, overlooking the city of Waterbury—on May 17 and 18. Callsign will be KA1YP, and the operation will run during daylight hours on 40-, 20-, and 15-meter SSB. QSL (SASE only) to *Callbook* address. Richard A. Jacovino KA1YP, 101 Woodbine Street, Waterbury CT 06705.

VE1 ABEGWEIT AWARD
MAY 18

The Prince Edward Island Amateur Radio Association will sponsor a special event featuring the little-known Abegweit Award on Sunday, May 18, from 1200 to 0000 UTC, SSB and CW only, with bands changing according to band conditions. CW—21.100, 14.050, 7.100, and 3.700; SSB—21.300, 14.250, 7.200, and 3.800.

Abegweit, a Micmac Indian word meaning "Cradled on the Waves," was the earliest name for PEI, which is located in the Gulf of St. Lawrence.

VE1 and VO1 stations must confirm contacts in all three PEI counties (Prince, Queens, and Kings). All other VEs and U.S. amateurs must confirm any three PEI stations. All amateurs other than continental United States and Canada must confirm two PEI contacts. Any such contacts since January 1, 1960, are valid.

Send a copy of the log, certified by two other amateurs, and $2 or 10 IRCs to PO Box 1232, Charlottetown, Prince Edward Island, Canada C1A 7M8. For further information, contact David A. Smith VE1CIK, Box 529, Kensington, Prince Edward Island, Canada C0B 1M0; (902)-836-4246 after 2200 UTC.

WABASH IN
MAY 18

The Wabash County ARC will sponsor The Indiana Hamfest on Sunday, May 18, beginning at 6 a.m. (setup time Saturday afternoon and evening), at the Wabash County 4-H Fairgrounds in Wabash, Ind. Overnight free parking for campers; tables available. Exams for Tech through Extra, 8 a.m. until noon. Admission will be $2.75 in advance, $3.25 at the door. Talk-in on 147.63/.03, 146.52/.52, and 146.94/.94. For more information, contact Donald Spangler W9HNO, 235 Southwood Drive, Wabash IN 46992; (219)-563-5564.

WILLINGBORO NJ
MAY 18

The Willingboro, N.J., Repeater Group will hold its annual Hamfest on Sunday, May 18, from 8 a.m. to 3 p.m. (setup from 6 a.m.) at the Holiday Lakes, Route 130 and Creek Road, Willingboro. Admission $3 (adults) or $2 in advance, $5 for table space/tailgate. Talk-in on 146.925, 224.860, and 146.52. For further information, contact Jack Engel K2KLM, PO Box 31, Rancocas NJ 08073; (609)-877-5249 after 6 p.m.

PARAMUS NJ
MAY 18

The Bergen ARA will hold a Ham Swap 'N' Sell on Sunday, May 18, from 8 a.m. to 4 p.m., at Bergen Community College, 400 Paramus Road, Paramus. Tailgating only; bring your own tables. Amateur license exams. Buyers free; sellers $5. Thousands of spaces. Talk-in on .79/.19 and .52. For further information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450; (201)-445-2855 nights only.

UNION ELECTRIC COMPANY
MAY 18

The Union Electric Ham Radio Club will operate special-event station KA0AWS on May 18 from 1800–2300 UTC to honor the employees of the Union Electric Company (serving parts of Missouri, Illinois, and Iowa). Operation will be 25 kHz up from the lower edges of the General portions of 80, 40, and 20 meters, and also on a 10-meter FM repeater on 29.620/.520 and a 10-meter repeater on 147.06/.66. Send your contact number and a large SASE (39 cents) for an 8-1/2 x 11 certificate to: Henry G. Schaper, Jr. KA0AWS, 241 Tapestry Drive, St. Louis MO 63129.

TAYLOR MO
MAY 18

The Western Illinois ARC will hold its 1986 Tri-State Swapfest (from 9 a.m. to 3 p.m.) in conjunction with the Experimental Aircraft Association's Fly-In Breakfast on Sunday, May 18, at Haerr Field, Taylor, Mo. (five miles west of Quincy, Ill., at the junction of State Routes 61 and 24). VEC exams will be offered for all license classes. Admission tickets $1 each or 6 for $5; tailgate flea-market spaces $2 in advance or $3 at the gate. Talk-in on the 147.03 repeater. For further information, write the Western Illinois ARC, PO Box 3132, Quincy IL 62301.

OMAHA NE
MAY 18

The AK-SAR-BEN ARC will host its annual auction on Sunday, May 18, at the Radial Social Hall, 1516 Northwest Radial Highway, Omaha, at 9:15 a.m. (equipment check-in starts at 8 a.m.). Food and beverages on the premises. No admission charge. Talk-in on 146.34/.94. For further information, call Greg N0BTN at (402)-895-5219.

FREMONT OH
MAY 18

The Sandusky Valley ARC will hold its annual hamfest at the American Legion Home, 2000 Buckland Ave., Fremont, Ohio (southwest edge of Fremont), on May 18, starting at 8 a.m. (open at 6 a.m. for setup). Advance admission $2.50; $3 at the door; 8-foot table space $6; free tailgate/trunk space; free parking. Talk-in on .52 simplex or 146.31/.91. For tickets and further information, send an SASE to Pat. D. Keating WB8KWD, 615 Lime St., Fremont OH 43420.

DALTON MA
MAY 18

The Northern Berkshire ARC will sponsor its annual Spring Flea Market at the Dalton American Legion, Route 9, Dalton, on Sunday, May 18, beginning at sunrise. Admission is $1; XYLs and YLs admitted free; refreshments by NOBARC. For further information, send an SASE to NOBARC, PO Box 591, Williamstown MA 01267.

ATHENS OH
MAY 18

The Athens County Amateur Radio Association will sponsor its 7th annual hamfest on Sunday, May 18, in the City Recreation Center on East State Street, from 8 a.m. to 3 p.m. The focus will be on the use of computer technology in ham radio. Packet-radio demonstration. Outdoor (paved) flea-market space free for tailgating or your own tables; indoor space by reservation only through Sam Stewart KA8NIE, 116 Franklin Avenue, Athens OH 45701; (614) 592-5330. License exams for all levels. Walk-ins accepted. Hamfest admission is $3 in advance and $4 at the gate. Talk-in on 146.34/.94. For further information, write Carl J. Denbow KA8JXG, 63 Morris Avenue, Athens OH 45701.

OLD WESTBURY NY
MAY 18

LIMARC will sponsor an ARRL outdoor hamfest at the N.Y. Institute of Technology, Northern Blvd., Rte. 25A, 1 mile east of Glen Cove Road in Old Westbury (Exit 39N-Rte. 25A), from 9 a.m. to 3 p.m. (7:30 a.m. for sellers). Plenty of parking; catered food. General admission for hams is $3. For further information, write Hank Wener WB2ALW, 53 Sherrard St., East Hills NY 11577, or call the LIMARC Infoline at (516)-796-2366.

CICERO IL
MAY 18

73 INTERNATIONAL

Just because I started this column as a result of visiting DX hams is no reason you shouldn't put in your 2¢ worth and let me know what DX news you find most interesting. My inclination is to have DX ops tell us what they think is interesting—how we can get permission to operate if we're fortunate enough to visit—any coming DXpeditions—what's doing with repeaters—things like that. What do YOU find most interesting? Since we have a world hobby, I think you'll be as interested as I in what is going on. If nothing else, it gives us something to talk about on the air which, from what I'm hearing these days, can't hurt.

—Wayne.

BRAZILIAN AMATEURS IN ANTARCTICA

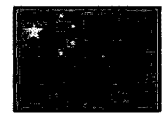
The third Antarctica Mission, sponsored by the Brazilian Navy, had in its crew two amateurs who put on the air for the first time the station ZXØECF, located on the King George Island, South Shetlands. Its geographic coordinates are 62.05 south and 58.23 west. The amateurs were Sinval Viana Silva PY1AFP and Nilson Gomes Silva PY1AFQ. They both used the special call above, issued by the Brazilian Communications Department (DENTEL) only for this event.

The equipment used was a Harris, which worked from 2 to 30 MHz, developing about 125 Watts, and an omnidirectional whip about 35 feet high. They were very active on 14 MHz, more in SSB than in CW because they had hard traffic between the crew (composed of 22 persons) and their families in Brazil. Meanwhile, they were able to work about 1500 different stations.

Last year, ZXØECF went QRT on April 30. The QSL information is PY1AFP or PY1AFQ, PO Box 58, 20001 Rio de Janeiro, RJ, Brazil. In 1986, during the 4th mission, ZXØECF will be on the air again for about five months.

In spite of affirming the Pact of Antarctica in 1975, Brazil started its scientific studies there only in 1982. During the second expedition a few regions were checked to decide where would be the best place to have the base. At first, five points were chosen to be visited: Dorian Bay, Port Lock Roy, Py Point, Andword Bay, and King George Island.

The last was determined to be the best because it has a wide area, a good place to anchor ships, and especially, was near a few foreign bases such as Teniente Rudolph Marsh (Chile), Jubany-Poter Cover (Argentina), Bellinghshausen (Soviet Union), Arctowski (Poland) and Chinese Wall (China), where they could have all kinds of help, considering that Brazil was a newcomer in that region. The assembly of the base lasted twelve days, and about 200 friends from the other bases came for its inauguration: the Brazilian base, the Comandante Ferraz Antarctica Station.



PIONEIROS RADIO CLUBE

Installed February 27, 1982, in the city of Recife, the PRC (Pioneers Radio Club) is a nonprofit organization of professional CW operators, active or retired, who are also ham operators. You may apply for membership by sending a copy of your professional license, your QSL card and 10 IRCs.

The Club was first directed by PY7HQ, PY7FI, PY7PO, (now PR7PO), and PY7FY. Carlos PY7HQ is still president. The PRC recognizes pioneer CW operators who maintained for many years in the past the only reliable kind of transmission. Already 49 Brazilian and 4 foreign amateurs have joined the PRC.

One of the activities of the Club is sponsoring the Worked Maritime Mobile Award (WMM), which is available to all licensed amateurs for confirmed contacts with 5 (five) stations maritime mobile of five different countries. For example: PY1ASI/MM, OH1SY/MM, JF6LZT/MM, DK2MI/MM, and YU3AG/MM.

Contacts must have been made after February 27, 1982, on any amateur band, only two-way CW mode. Minimum report is 338. Send your list of stations worked (call, date, time, band, mode, and report), copies of the five received /MM QSLs, and 10 IRCs for mailing expenses to: PRC, PO Box 1470, 5000 Recife, PE, Brazil.

Taipei, Taiwan, 107
Republic of China

GOLDWATER VISITS

United States Senator Barry Goldwater K7UGA recently made a trip to Taipei, Republic of China; this long-wished-for expedition was postponed since November, 1984. The mission consisted of seven members, including the Senator himself, David Siddall K3ZJ, Larry Kettlewell W3HHG, Thomas J. Warren K3TX, Roland McElroy K4OCI, Jeff Hutchinson W4PBC and Karl Renz K4YT.

K4YT came from Manila alone and the others arrived in Taipei on January 2, 1986 during the New Year holiday. Three monobander beam antennas for 15, 20, and 40 meters with 2 linear amplifiers, 30L-1 and Dentron MLA 2500, were brought in from Manila and the States. The antennas were transported from the international airport to Taipei and immediately installed at two different locations for the seven-day operation. In addition, four transceivers, TS-930S, FT-901D, TS-430, and IC-741, were borrowed from local hams.

The two locations are separated by about 3 km, one of them the same QTH near the suburb park provided for use by the six DXpedition groups in the past, and the other, a new QTH situated at a high-rise 13-story building downtown. These arrangements were made in honor of Senator Goldwater, who would open the station, and for the convenience of simultaneous operating without causing any interference.

At 5 p.m. on January 5, Mr. Lien Chan, Minister of Communications, personally handed station license BVØBG to Senator Goldwater, wishing him every success for the DXpedition. The Minister said, "This is really a unique activity."

There were about 20 reporters from local TV stations and news agencies crowded in the station. The flashlights and floodlights made the decorated hall even brighter and more colorful for photographing. Our activities caught all eyes with admiration through the three TVs and most important papers on the following day.

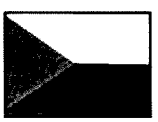
Mr. Y.C. Huang (ex-C9YC), Secretary General of the China Radio Association, presented the senator with a hand-painted scroll with a picture of the senator standing beside a gnarled pine tree. The picture depicts the idea of longevity, and the senator accepted it with great pleasure. Six ham members of the mission also received a medal with a certificate of appreciation and a souvenir from the CRA. Meanwhile, Senator

Senator Goldwater received the BVØBG station license from Minister Lien Chan. David Siddall K3ZJ looked on.

At the China Radio Association Banquet, (l to r) Roland McElroy K4OCI, Larry Kettlewell W3HHG, Y. C. Huang, ex-C9YC, David Siddall K3ZJ, Karl Renz K4YT, Garry Denitto of AIT, Thomas Warren K3TW, Jeff Hutchinson W4PBC, Tim Chen BV2A/BV2B, and H.C. Hu, Secretary of CRA.

Goldwater honored the CRA by giving a set of American-published amateur radio literature to BV2A/BV2B (the writer), as chairman of CRA Amateur Radio Commission. It included a copy of the ARRL 1986 *Radio Amateur's Handbook* bearing the Senator's autograph.

Returning to a CQ call, five stations from Marshall Island, Japan, and the Philippines got contact with the senator. It was regretful that he could not hold on longer on the air owing to participating in another party. Then someone else took over the mike and continued the QSOs.



That evening a banquet was hosted by the China Radio Association at the Lai Lai Sheraton Hotel to welcome the DXpedition as well as to commemorate mutual goodwill and friendship. Many officials of the government's Information Office, Ministry of Foreign Affairs, Ministry of Communications, and the American Institute in Taiwan were present. The party ended in joy.

On January 10, the mission was satisfactorily accomplished and all members left for the States. By a rough estimate there were approximately 7000 QSOs with 73 countries contacted on 160, 80, 40, 20, 15, and 10 meters. It is noted that the mission initiated the use of 160 and 80 in this area, but this was a temporary measure, specially approved for the expedition, and can not to be considered as a practice. 80-meter operation created some TVI, which we should try to remedy.

Many new ham calls are active on 7, 14, and 21 MHz. From this area, they are BV2DA, BV2FA, BV5HA, BV6IA, BV7JA, BV7KA, and BV7LA. Moreover, BV2GA, BV7MA, BV5NA, BV2OA and BV8PA are underway to complete their installations within one or two months. Most of these new ones run barefoot at present, although some of them have got 3-element or 5-element beam and linear amplifiers on hand.

Also, be aware of bootleggers —BV9CR, BV0BA, BV0RL and BV0JC are under investigation.

Thousands of DX have been contacted by BV0CRA in the months of November and December, 1985. This special callsign was assigned to commemorate the occasion of the 30th anniversary of the China Radio Association. A demonstration of amateur radio operating took place at its annual convention on November 30, 1985. Two transceivers and two antennas (one 15-meter beam and one tribander vertical) were installed for the operation from morning till night; it attracted 500 visitors. The QSL cards for BV0CRA are ready and being dispatched.

CZECHOSLOVAKIA

Czechoslovakia

QRP IN CZECHOSLOVAKIA

To the list of other OK stations that deal with operation with low power belong also OK1DNM, OK2SAH, and OK3CXS. Milan OK1DNM works with various powers from 50 Watts to 9 Watts. Among his connections there are some partials that have been made with an input between 50 and 100 milliwatts by CW and from 100 milliwatts to 3 Watts operating SSB. With his contacts with VE1 on 14 MHz by 4 Watts and with F on 10 MHz by 50 milliwatts, Milan fulfilled the condition of the diploma 1000 milliwatts.

Alois OK2SAH works on various bands with the longwire antenna by a transceiver of 5 Watts. The transceiver is his own product and it is a faithful copy of the Argonaut of the Ten-Tec firm.

Peter OK3CXS specializes in the 160-meter band where he uses the transceiver M-160 (made in Czechoslovakia) and thanks to the excellent antenna he reaches remarkable results. On the abovementioned band, operating QRP, he has made more than 1000 contacts with 46 states on three continents, according to the DXCC list. To his most interesting contacts belong, for example: EA9, SV5, UA9, UF, UG, UL, UM and 4X4.

With one Watt, he has fulfilled the conditions of the diplomas WAE, W-1000-U, and 100 OK with 1000 milliwatts. He also successfully competes with stations whose capacity is two or three times higher.

On every first Friday of the month, experiments of the OK QRP Circle are held from 1700 UTC on the frequency of 3560 kHz, from 1800 UTC with less than 1 Watt, and from 1900 UTC, with a sufficient number of participants, also on 1875 kHz.

RS SATELLITES

For the converter 21 and 29 MHz, the indication mode K is used. Soviet satellites RS9 and RS10 (except the mode A) are to be equipped with this converter. At least one of the satellites will have an experimental converter mode T with an input channel on the 21-MHz band and with an output on the 145 MHz.

During April 1985, Ondrej OK3AU worked several times with the station from Alaska, KL7JIZ in Fairbanks, through the converter on the satellite RS8. The condition for making contacts for such a great distance lasted approximately 90 seconds.

RTTY

The members of the Radioclub OK1KRY from Rokycany are again very active when operating RTTY. They use the converter ST-5, the teleprinter T-51 and the transceiver "OTAVA" (80–10 meters operation CW/SSB, input of 70 Watts, the product of the firm Radiotechnique in Czechoslovakia). With the help of RTTY they were working with 80 countries according to the DXCC list.

DX

The station EO1AOK was broadcasting from the island Heiss that belongs to the group of islands Franz Jozef Land. If you had been working with it, send QSL via UZ1OWA. In winter 1985/86, UV1OO, UA1OT, and UZ3DD/1 were able to be active from Franz Jozef Land. For all stations, UZ1OWA is manager.

50 MHZ IN THE UK

1986 undoubtedly will be the year of 50 MHz in the United Kingdom. I have already reported the release of the 50-MHz band to UK amateurs following sterling and lengthy efforts by the Radio Society of Great Britain (RSGB). The Society is rightly proud of its efforts in this area on behalf of the UK amateur population, losing no opportunity to let everyone know.

The January 1986 edition of *Radio Communications*, the Society's monthly journal, contained a six-page special on 50 MHz together with a facsimile of the letter received from Barry Maxwell, head of licensing at the UK regulatory authority, the Department of Trade and Industry, Radio Regulatory Division.

The letter sets out the main conditions of the allocation. (In typical British bureaucratic style, the letter emphasis is on all the bad news, particularly the threat of withdrawal if interference is caused to authorized radio services in other countries.) The conditions are:

- usage will be primary (i.e., amateurs have first call on the band)
- only Class A license holders allowed
- maximum power is 20 dBW erp PEP
- maximum transmit antenna height is 20 meters above ground level
- antenna polarization is limited to horizontal
- operation is permitted only

Continued on page 104

73 INTERNATIONAL

from page 100

from the amateur's fixed (home) station

•no repeaters permitted.

The existing special permits for restricted use of 50 MHz by a small number of amateurs are withdrawn. There are no limitations on the mode of operation to be allowed on 50 MHz, so we can expect to see SSTV, RTTY, fax, and data as well as the more traditional modes. With the full availability of 50 MHz from 1st February 1986, it is likely that a number of *73* readers will have added UK contacts to their band totals by the time this is read.

The most significant restrictions seem to be the combination of antenna height and polarization, fixed station operation, and limited power. The regulatory officials are very concerned at the potential for interference with Band 1 television stations in nearby countries. Belgium and Norway particularly are at risk from stations in the south of England and northeast Scotland, respectively.

Clearly the needs of other spectrum users must be properly considered, but I am not sure what answer one would give an Antwerp TV viewer plagued with interference in the middle of a lift...

Just to remind those looking for UK contacts on 50 MHz, there are three 6-meter beacons in the UK: GB3RMK on 50.006, GB3SIX on 50.020, and GB3NHQ on 50.050. GB3SIX has the most power at 100 Watts erp, and is the only beacon to beam west towards the new countries.

You will recall that a full (Class A) license in the UK requires the applicant to pass a Morse test (12 wpm send and receive) in addition to the written examination. To date, Morse tests have been conducted by the Maritime Branch of British Telecom on behalf of the Department of Trade and Industry. Taking a test has been possible at more or less any time (by appointment) but has necessitated a visit to the Maritime Branch's nearest shore station—often a considerable journey.

From April 1, 1986 tests will be available at over 70 testing centers throughout the UK, with every county having at least one location. Tests will be held every two months in each center and at £7, will be less than half the present fee. Once again the improvements are due to the RSGB who have successfully competed with the City & Guilds and British Telecom for the "contract" to operate the service on behalf of the Department.

The RSGB-recorded "newsletter" is updated frequently and provides up-to-the-minute information on happenings in the amateur scene in the UK. The number is 707 52242 (from the US, precede this with 01144).

MEXICO

Mark Toutjian XE1MKT
Apartado Postal 42-048
06470-Mexico D.F.

TRAVELING TO MEXICO?

Traveling to Mexico? You say you would like to get a temporary ham license so you can operate during your stay here? Then I am pleased to provide the following new information.

Since there is no reciprocal agreement between Mexico and the United States and some other countries, obtaining a permanent license may not be possible—unless you want to take the tests involved (in Spanish). However, if you plan to visit Mexico on a temporary basis, how about a temporary license (mobile and/or base station)?

If this is what you want, here are the rules:

1. You must already be a legal ham operator in the country where you reside.

2. Present a photocopy of your valid license.

3. Obtain a letter of recommendation from a Mexican ham. You probably already have made friends with Mexican hams over the air waves. (Note: I cannot give out recommendations because I am not Mexican—although you would never tell by my accent—ha!)

4. Present a photocopy of your tourist card.

5. Indicate in writing an address in Mexico where any correspondence from the Mexican Communications Bureau can be sent to you while you are in Mexico.

6. Indicate in writing where your base station will be located.

7. If you plan to operate mobile, indicate in writing your probable itinerary—locations and dates—during your stay.

8. Be sure to keep an accurate log of *all* your contacts made from within the country, and send a copy of this to the Mexican Communications Bureau as soon as you leave the country.

All of your correspondence can be directed to:

Dirección General de Concesiones y Permisos de Telecomunicaiones
Dirección de Control de Operación de Sistemas Radio Eléctricas
Apartado Postal 55-258
Col. Iztapalapa
09820-Mexico, D.F.
Telephone in Mexico City: 692-0412. Ask for Raymundo Méndez or Jesús Alberto Felix. (A little Spanish will help.) They will be pleased to help you.

If you plan to stay in the border area around Tijuana, you can direct your correspondence to:

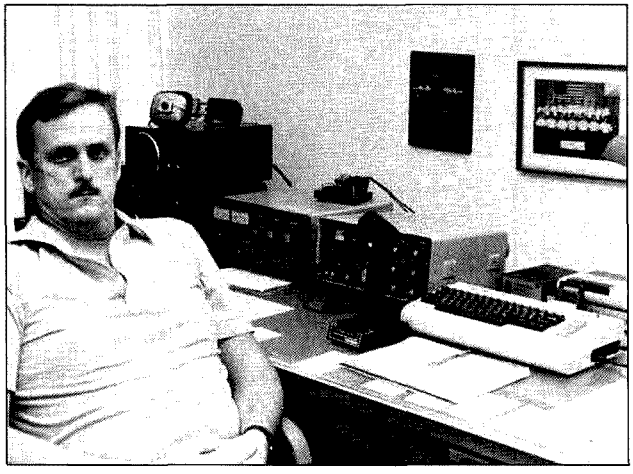
Delegación Regional de Concesiones y Permisos de Telecomunicaciones
Lic. Hector Bravos Velarde
Blvd. Adolfo López Mateos 1431
Col. Centro
Mexicali
B.C.N. Mexico

The telephone in Tijuana is 571-208. Ask for Hector Bravos Velarde.

You can ask for a license of the same amount of time authorized on your tourist card. (This can be anywhere from 30 days to six months.) Some who enter Mexico other than as tourists can ask for up to a full year.

It would be good to plan to get your tourist card (or visa) well in advance so that you can include a photocopy of it in your letter with the *other* requirements. Of course, this would be advisable for all of the above points.

Hope this helps answer the many inquiries I have received by mail. I had written to some of you, mentioning that you would have to apply for a permanent license and take the usual tests. However, the above is *new* information that will hopefully be useful for your next trip to Mexico! So, enjoy your vacation and "hasta pronto."



MOZAMBIQUE

Charles E. Martin AB4Y
American Embassy
Department of State
Washington DC 20520

The views and opinions presented are my own and not necessarily those of the State Department or the US Government.

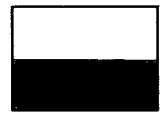
This is my final column from Mozambique. Sadly, I have not been able to secure operating permission. Amateur radio remains "suspended" in the People's Republic of Mozambique, and unless conditions change radically the suspension is not likely to be lifted soon.

The medium- to long-term outlook is, however, promising. Rui Fernandas, the director of CTT (the *parastatal* that administers telecommunications in the Re-

Guam: Our man in Guam: AH2BE (ex KB6DAW/KH2/KH9).

public) is now receiving *QST* and *73* every month. The many positive aspects of amateur radio are now regularly seen by an individual who may be important in returning amateur radio to this country.

Mozambique is a member of SATA (Southern African Telecommunications Administration). SATA is a suborganization of the Southern Africa Development Coordination Conference. The long-term goal of SATA is to expand and link the telecommunications structure of the various member states. A number of telecommunications projects are underway in Mozambique, including expansions of both in-country telephone and telex services and a new satellite communications terminal in the port city of Beira.



By way of statistics, Mozambique, a country of some 14 million people, has about 52,000 telephones—or one per every 270 people. Most of these telephones are in Maputo. (By comparison, there are more telephones in Tokyo than in all of Africa.) SATA has a formidable task ahead of it. Most of the technicians involved in the upgrade projects are foreigners and are paid in foreign currency, which usually is in short supply in Africa.

All SATA member states except Mozambique permit amateur radio in their respective countries. Perhaps Mozambique will re-authorize amateur radio as a step toward rehabilitating the telecommunications infrastructure and providing a source of trained technicians in the future.

I have been posted to the American Embassy in Paris, France. If you are ever in the neighborhood, just drop by. I will, fortunately, be licensed in France, and I plan to do a great deal of operating. After two long years without amateur radio privileges, it will be great to get back on the air. Perhaps a DX-pedition to C31 or 3A can be arranged.

I am grateful to Perry KW1O and the staff at *73* magazine for the opportunity to write this column. I am sad only about the fact that I could not report any return of amateur radio to Mozambique.

73 and God bless.

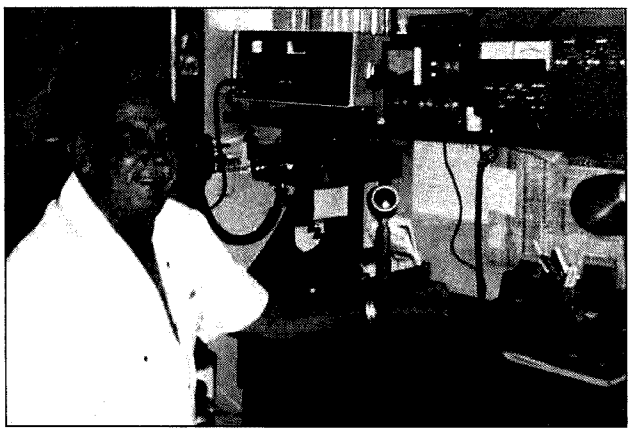
POLISH USW CLUB

On June 8th and 9th, 1985, the XXIV Conference of the Polish USW Club took place in Bydgoszcz. The Polish USW movement was represented by 90 participants, among them 50 full members of the club. The Conference elected a new board, with SP9EHS as the president, SP2DDV as secretary, SP9GMT as technical manager, SP6GWN the treasurer and SP6AZT the member at large.



During an hour-long discussion, 19 motions had been brought forward but only 16 of them were adopted. Regarding a contest organized by Eastern Bloc countries, under the name "Victory 41," the Conference adopted a resolution in favor of filling "silent squares QTH" which may appear during the contest.

For many years the USW Club has applied for the right to elect a USW manager at headquarters of PRAA. In a vote adopted by the Conference, the USW Club said it should be able to name know-how USW and microwave managers at the PRAA headquarters. The USW Club should promote the candidates to the National Congress of PRAA with suitable justifications.

Other very important matters, relative to licenses for "portable" and "mobile" modes of work, and use of home and summer QTHs on the basis of permanent permission, were adopted by a solid vote. These new possibilities would contribute to the growth of the SW movement in Poland.

A subsequent vote insists amateurs should be granted microwave bands, using modern kinds of modulations, and transmitting computer data. The XXIV Conference of the USW Club firmly asked for a mail-order technical information center at PRAA headquarters, conforming to a resolution of the general assembly of PRAA in Chorzów.

A few technical lectures were given at the Conference. A lot of interest arose about antenna problems, especially after a SP6LB lecture on antennas with vertical polarization. The president of PRAA, SP5JR, presented his research on the subject of shortwave and microwave propagation and the ground effect of their propagation.

The "grumpy old bloke from Down Under," VK3YJ.

Australia: Preparing the ground for the "new" radio room. The old one (a caboose) is in the background. (See April, 1986 column.)

Jack VK5EJ, the ex-, and Carol VK5PWA, the current president of LEPARC.

Tooth and nail enough to get the FCC to say "no." Good work, guys.—Ed.

OPEN LETTER

Richard Baldwin W1RU
President, IARU

Dear Dick,

The December, 1985, issue of *QST* features a fine article, "Cruising and Amateur Radio," in your IARU news column. In addition to the pirate and unlicensed operation that was mentioned, there are several other unsavory aspects of "cruising" that should be brought to light. What we have is the erroneous belief it is not necessary to obtain "express permission" to operate amateur gear sailing or anchored in another nation's waters. The fact that our licensees aboard sailboats are most vociferous in pushing this concept rather than being passive participants is cause for alarm. After communicating with hundreds of "cruisers," I quickly learned that most of them were mainly drawn toward to the amateur spectrum because it produces a toll-free telephone communication from their yacht to any place in the world. The fact that most of this toll avoidance takes place from foreign jurisdictions certainly represents a clear and present danger to our amateur radio treaties.

If you care to observe the daily spectrum violations, please monitor 14.313 MHz or any of the many "Mickey Mouse" nets that you listed in your column. With the exception of a few Merchant Marine and military vessels, not many of the "cruisers" ever get on the air while actually out on the high seas or in true "international waters." Seldom do "cruisers" ever sail out of sight of land but rather bump along coastlines or from island to island. While sailing, use of amateur equipment is rare because there is just too much activity topside to permit ham-radio use. Most of the phone patching by "cruisers" is evident while they luxuriate in a foreign marina close to all the entertainment.

There is an urgent need for pro-amateur groups worldwide to launch a positive program of education and encouragement of legal use of amateur radio aboard sailboats. The "net junkies" and "network commanders" should receive the hard cold facts of law when they contribute to the numerous daily sovereignty violations by aiding and abetting the cruising violators with such patronizing statememnts as: "they must be underway" or "they are Mickey Mouse off Baja." The fact of the matter is that when a vessel enters a country it remains under that country's jurisdiction until the vessel is legally cleared out. Except for a few cruise ships subject to reciprocal treaty, each boat must be cleared out to a foreign destination. Many "cruisers" foster the ruse that they are "Mickey Mouse" in the Bahamas in order to allow for phone patching while they are actually domiciled on their vessels as visitors of that country. They would now have us believe that even though the boat is in Bahamian waters and their visa is in effect, that by some magic the amateur station can be instantly transported into international limbo-land by saying "we are now underway." The bottom line is that leaving a country's jurisdiction, if done legally, involves more than a mental whim. Please do what you can to place this matter before the IARU and ARRL for a consensus and appropriate action.

73.

Herbert Schoenbohm KV4FZ
Christiansted USVI

MEDIEVAL MEASURING

The comments I am about to make are inspired by articles in your magazine and, indeed, other ham-radio publications in the United States.

I am referring to the continued use of the "medieval" imperial system of measurement in construction features, antenna designs, etc. There can be no excuse for continuing this hodgepodge of measurements in electronics of all things, a science where all the units of inductance, frequency, etc., are SI ones (SI=International Standard).

Where, for example, is the logic in measuring a half-wave dipole for 40 meters in feet?

Also, amateur radio is supposed to foster communication amongst people. According to an article in the *Wall Street Journal*, there are only three countries left in the world still not officially metricated. Guess who? Burma, Brunei, and the United States.

Be progressive—educate your domestic readers. There is no way of pleasing the "imperial lobby" by the consistent use of imperial measures, even if this was considered desirable, since such measures do not exist for most electronic parameters (thank goodness). There is a way of pleasing the rest of us, with the consistent use of SI units.

Perhaps the American amateurs in their journals would care to take the initiative? Let the only feet we read about in ham-radio magazines be attached to cabinets or propping up the editor, and the only pounds be those charged when shopping in the U.K.

Ragnar Otterstad
LA5HE/OZ8RO
Holte, Denmark

MIRAGE IS REAL

How often have you purchased an item which later developed a problem and getting it fixed was an even bigger problem? Well, rejoice! There is a manufacturer who stands behind its equipment.

I was pleased with my Mirage amplifier's performance. One day, after a long-winded QSO, the power amp on a B3016 2m amp quit in a puff of smoke. The amp is used at home with a blower to keep it cool which, considering its good heat sink, is unnecessary but helpful for long key-down times.

I sent the unit, which was a couple of years old, in for repairs. Needless to say, I was surprised to have it returned promptly and with NO CHARGE marked on the invoice. I had expected a long exchange of purchase receipts, letters, charge-card info, and the like. What a nice surprise to have a warranty repair done quickly and without a quibble. I use three of their amps, two at home and one mobile, and have found them to be well made and long lasting even in the 100% duty cycle of ATV operation. I would recommend Mirage to anyone who wants a quality product.

Henry B. Ruh KB9FO
Chicago IL

ISHMOD OUTRAGE

My subscription to *73* just expired and I'm glad. I feel that I have wasted money on the last 18+ months of my multi-year subscription. I used to look forward to receiving *73* every month, but not anymore.

Almost two years ago, in the April issue, an unfinished article appeared in *73*, entitled "Ishmod's Journey," or something like that ["Ishmod's Journal," April, 1984]. It was continued to a nonexisting page. You pulled the same stunt in last April's issue (which I received a few weeks prior to April Fools' Day). There have been mentions of Ishmod in your publisher's column, praising the author. And there have been letters from readers regarding "Ishmod" with the response continued to another nonexisting page. This type of reading is not what I expected from *73* when I subscribed many years ago. I realize that change is necessary, but in my opinion, *73* has changed for the worse. These "Ishmod" articles, in my opinion, were designed as a gimmick to get readers to scrutinize every page of your magazine looking for the conclusion to the article and also provide your advertisers with more exposure than usual.

I do not get the insight into ham radio that I used to from *73*. There are fewer and fewer articles of interest to me and it seems like fewer articles in general. I do not want to go into more detail as I feel that I already wasted too much time and money on *73*.

Alan H. Carp K1HLZ
Natick MA

These "Ishmod" articles, in our opinion, were designed to give 73's readers something to chuckle over. Maybe you've forgotten, but ham radio is supposed to be fun. *And if you'd bother to compare 73 with the other ham rags, you'd notice that, month after month, 73 publishes more articles. Period.—KW1O.*

G=Good, F=Fair, P=Poor.

Look for some disturbances in magnetic field between 5th and 10th with possible storm levels; also possible 6- and 2-meter openings in this period. Again, between the 27th and 30th look for active magnetic field conditions and generally poor propagation on HF, LF, and VHF.

73 Amateur Radio

ISSUE #309 JUNE 1986

A WALK THROUGH THE VHF/UHF SPECTRUM 28
This is for all of you who've spent the last forty years on 75-meter AM. KT2B takes us on a guided tour through the five most popular bands above 50 MHz, explaining who's there and just what they're doing.

NASA INTERVIEWS 34
73 asked hams-in-space Owen Garriott W5LFL and Tony England WØORE what they've been up to since their historic flights. You'll be surprised by their answers!

TWO TO TEN 38
Have you tried ten-meter FM? Repeaters are popping up all over the country, and the range is sometimes startling. WB5IPM's little gadget lets you use your two-meter gear to check out the action.

SOME GUYS MAKE IT... 46
OK, we cheated. Those of you who have been reading *73* for the past twenty years have seen this one before. You'll laugh just as hard this time as you did before.

DIGITAL SIMPLEX REPEATERS 48
This combination of packet radio and FM voice repeaters might be a way to ease the overcrowding on our VHF allocation. The system's creator looks at the how and why of store-and-forward voice repeaters.

MESSING WITH MICROWAVES 52
You won't believe how simple it is to play with frequencies in the GHz range. You won't spend a fortune, either, so you can build up two of these stations and have someone to talk with.

THEY THREW WHAT AWAY? 58
Yes, Uncle Sam is up to it again...for the price of scrap aluminum you can get dandy UHF swr bridge. Never mind that you've already paid for it...

THOSE TANTALIZING TWOS 88
Sorry about that title. Get out your tweezers and screw up your courage! Now pop the cover off of your beloved IC-2 or IC-02. A snip here, a tuck there, and *voila* you're holding a 140—162-MHz scanner.

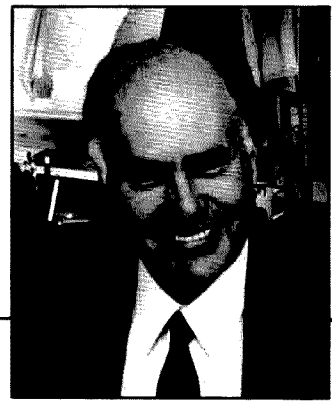
REVIEWS 28, 24
Two reviews for you this month. Above and Beyond columnist Pete Putman KT2B pits ICOM's IC-471A and Kenwood's TS-811A against each other in a head to head battle of the UHF multi-modes. And Marc Stern N1BLH presents the first look at MFJ's hot new packet TNC, the MFJ-1270. Is it the TNC for the masses?

Astronaut Owen Garriott W5LFL

NEVER SAY DIE 4
Really must reading for June. Contains the "missing editorial" absent from the May issue. (OK, since you asked, due to an "editorial oversight" we, ah, forgot to run part of Wayne's column. Just a little part. It's the first time in NSD—*don't miss it!*

DEPARTMENTS

LOOKING WEST & QRP 84, 88
These columns bring back an old friend and introduce a new one. QRP and antenna enthusiast Bill Stocking WØVM opens shop with a monthly feature, mercifully *not* called "Stocking's Stuffers". And we welcome back Bill Pasternak WA6ITF to his old spot in Looking West. Bill has been with *73* since the beginning, and always manages to find something unusual happening on the West Coast. Sometimes he tells us about it.



FUN! 83
KI2U has done it again. The annual Fun! poll, that is. This is the pulse of amateur radio, the heartbeat of hamdom, the...well, youget the idea. This year the poll turned out some unexpected results.

RTTY LOOP 74
Must reading for June. Marc Leavey has come up with an incredible poem about finding a program for the Macintosh. Suitable for framing.

Legal Contract: The mere opening of the pages of this magazine, even for a hasty glance at the contents, is hereby declared to be a legally binding contract between the purchaser, whether by paid subscription, newsstand purchase, or purchase at an electronics store, and the publisher. This is every bit as legally binding a contract as signing your name, nodding your head in agreement, or tearing the plastic wrapping from a software package. Under penalty of copyright infringement, considered virtually a hanging crime by many courts, you are hereby forbidden from reproducing choice articles from this magazine for distribution to low-life hams who are too cheap to buy their own subscriptions. You are further, under severe penalties, proscribed from lending your copy of *73* to a licensed amateur friend, acquaintance, neighbor, or even enemy for other than the purpose of a brief scanning of the table of contents, which should include supportive comments by yourself and an offering of the blow-in subscription card. Heavy penalties, including, but not completely restricted to a lifetime of crushing guilt, an increasing paranoia that the dedicated minions of *73* will discover your perfidy, or that Wayne Green, in a bad moment (of which he has plenty), will put a curse on you and your issue for 73 years. You are further directed by the terms of this contract to speak enthusiastically of *73* Magazine at least once during every radio contact you make. While it is not absolutely imperative that you include a *73* subscription blank and your personal endorsement with your every QSL card, your conscience will be much clearer if you do this. Suitable subscription blanks are available from *73* for only $1 per hundred. The extension of your subscription by two issues for each of these subscription cards received by *73* (with credit card payment) is not to be construed as a bribe of any sort. Please just consider it a personal thank-you from Wayne for your help.

Postmaster: Send address changes to *73 Amateur Radio*, Subscription Services, PO Box 931, Farmingdale NY 11737. Nationally distributed by International Circulation Distributors.

NEVER SAY DIE

COME FLY WITH ME

Are you game to sit down at a rig in a rare DX spot and face the pileups?

A few years ago I started going to Asia every October to see what was new at their yearly consumer electronic shows. It was so much fun that I wrote about it in *73*, urging readers to join me. This resulted in more and more hams going on the tour each year—many repeaters, like me.

On the 1985 trip several of us got to talking about how much fun the trip was, and that got us thinking in terms of organizing a ham expedition for 1986—one which would take us to Korea, Taiwan, and Hong Kong. We thought about including Japan, but with the present cost of the yen—the difficulty of getting a ham license—better off without it.

We should be able to get a license for everyone to operate in Korea, Taiwan, and Hong Kong, so it would be a real ham trip. Also, I think we'll be able to get the local hams to host us, allowing our group to see how it feels to sit and work DX from Asia.

Bob Norman K4GRD was particularly enthusiastic about this idea—excited enough to agree to do most of the work (heh, heh). The tour part will be organized by Bob Chang, who's been running the consumer electronic and computer show tours to Asia for about eight years now. Chang does a fabulous job—which is why there are so many of us who have been making the trip year after year.

If there are enough readers interested in the DXpedition, Bob will organize a hamfest in each city for you to meet the local hams—and perhaps get invited to their homes and operate their station.

I ran a ham tour in 1963 that was a corker. 73 of us—hams and wives—went to London, Paris, Geneva, Rome, and Berlin. I still run into hams at hamfests who tell me that was the best trip they've ever taken. We had a banquet/hamfest with the hams in every city but Rome. We got to visit ham homes and operate.

In Rome we had an audience with the Pope and went on a tour of Vatican radio. In Geneva we got to operate 4U1ITU and in London many of us operated GV2SM at the Science Museum, then the only station in England permitted to handle third-party traffic.

For younger hams—and old ones with short memories—it was while we were working on this tour that the ARRL filed its Incentive Licensing proposal with the FCC—the docket which almost instantly stopped the growth of amateur radio—put 85% of the ham dealers and almost 100% of the manufacturers out of business. With amateur radio self-destructing, that put an end to ham tours.

By the time amateur radio had recovered enough so that a tour might be practical again, I was up to here in computers and starting new computer magazines. I'm not sure that even now we have enough hams with the spirit it takes to go on a DXpedition to Asia.

The tour part is fun in itself. We'll be able to get to the consumer electronic shows in Seoul and Taipei. I enjoy these because I often find products worthy of being imported by my Wayne Green International division—you may have seen ads for Pico Products. It only takes one hot mail-order product to make millions, you know—lots of people have done it.

"While we were diggin' you a deeper ground, we struck oil!"

QRX . . .

EDITED BY PERRY DONHAM KW1O

Novice Phone

THE FCC has proposed an enhancement to the present Novice-class license. The Notice of Proposed Rule Making, **PR Docket 86-161**, calls for data privileges from 28.1 to 28.3 MHz, SSB from 28.3 to 28.5 MHz, all amateur privileges from 220 to 225 MHz, and simplex and repeater privileges from 1246 to 1260 MHz. Power restrictions would be 200-Watt PEP on ten meters, 25 Watts on 1-1/4 meters, and 5 Watts on 23 centimeters. Higher-class stations would be allowed to run the full legal limit in the Novice portions of these bands. Further, Novice licensees would not be allowed to be trustees of a repeater station, although they would be allowed to operate through a repeater. Technicians, because of the structure of the license system, would gain the additional privileges of the Novice enhancement. The FCC is very interested in hearing ideas on several points. Should the Novice-license term be reduced to two or five years to encourage upgrading? Should questions be added to the Novice test to cover the new privileges? Should more than one person administer the test, or should Novices be tested through the volunteer-examination program? Should Element 3 (the General-class exam) be broken into two parts—part A to cover VHF and repeaters and part B to cover HF operation—to make it easier to upgrade from Novice to Technician? Comments on the proposal are due at the commission by July 16th, and reply comments must arrive by August 20th. Send your original comment plus five copies (11 copies if you want each commissioner to have one) to the FCC, 1919 M Street NW, Washington DC 20554. Please include the Docket number in the head of your document.

Albania Mania

GUS BROWNING W4BPD, writing in his *DX'ers Magazine*, reports that OK2RZ and five other Czechoslovakian amateurs have obtained permission to operate from Albania. The DXpedition to ZA is expected to begin around the 20th of September—watch QRX for details. Gus also mentions expeditions to Vietnam and Yemen . . . it looks as though DX is beginning to pick up a bit. The *DX'ers Magazine* is a great source for up-to-minute news; you can write to Gus at PO Drawer DX, Cordova SC 29039. (Tell him you think *73* deserves a kickback for plugging his rag.)

Techno-Tantrums

WHO WOULDA THOUGHT that our announcement of the first 900-MHz amateur communication (QRX, January, 1986) would trigger a range war? **Chuck Gollnick KA7QEN/0** of the **Iowa State University Cyclone Amateur Radio Club** contends that they, not **Mike Krzystniak K9MK/5**, are the rightful holders of the title. Now, this would not be so bad so long as one or the other could produce documentation of the exact time of the contact. Chuck and the boys at Iowa State drew first blood by describing their system: "Our first transmission was keyed by time signals received from WWV. Considering the propagation delay between WWV and Ames (Iowa), the delay in our decoder circuit, and the key time of our transmitter, the signal was transmitted no more than 50 milliseconds after the legal band opening, and probably less than that." To which Mike countered, "I have no doubt that we [members of the Motorola Radio Club in Ft. Worth] beat your alleged 50-milliseconds-after-the-band-opened claim by at least 49.999999 milliseconds. I cannot disclose the commercial techniques that we used to do this with as they are . . . currently proprietary." In the second round, Chuck and the Cyclones pointed out that, "Our first transmissions . . . were made *after* the band was legally open. If . . . your clock was not calibrated to the NBS standard and was, say, just 5 nanoseconds fast, . . . then your first transmissions would have occurred at least 4 nanoseconds *before* the 900-MHz band was open for legal use by amateurs, which would qualify you as the first amateur to earn a pink slip on 900 MHz." In the interest of fair play, and in the spirit of ham fellowship, I think we should point out that Iowa State's transmission was the first *AM* transmission, and the Motorola club's was the first *FM* transmission. Give or take a nanosecond.

OSCAR's Out

AMSAT-OSCAR 10 will not be available for this year's ARRL Field Day exercise, according to the *Amateur Satellite Report*. AO-10 Command Station ZL1AOX indicates that the bird will be visible only during perigee and that it probably will not be turned on due to eclipses during that period. Meanwhile, work is progressing on the next Phase III satellite, which is scheduled for launch aboard an Ariane booster later this year.

Turkey and Ham

AMATEUR RADIO ACTIVITY in Turkey is still increasing, with more than 20 stations now licensed. **Salim Unuver TA1B** details some of the action: "Lots of [Turkish hams] are usually on 14-MHz SSB or CW. Every night, U.S. hams can find TA stations on 14.200 MHz at 1900 UTC. You will hear perhaps TA1C or TA1E, because they are using 3-element beams and running the legal limit of 400 Watts PEP. Other TAs are running 200 Watts to a dipole or ground plane, like me and TA1F, and we are running RTTY on 14.180 each night at 1900, and all day on Saturday and Sunday." Salim points out that TA1 stations are located on the European side of Turkey, while TA2–9 indicates stations on the Asian side. TA0 calls are assigned to stations on Turkish islands.

Salim Unuver TA1B at his station in Ankara.

New SIN

IF YOU PARTICIPATED in the National Six-Meter Invitational Net Activity Day Contest [whew!] on May 31st–June 1st, please mail your logs to Lisa Lowell KA0NNO's new address: PO Box 547, Hugo CO 80821.

Malibu Good Guy

DANIEL GOODKIN KA6VVS, Novice at age 7 and General at age 11, has become the youngest member of the Los Angeles County Disaster Communications Service (a part of the Radio Amateur Civil Emergency Service). Daniel has already earned two commendations from the Malibu Sheriffs Department for his work during the recent Lake Sherwood and Carbon Canyon fires, where he worked for several days carrying messages between key command centers. Belonging to the DCS is a family affair for the Goodkins; Daniel's father Norm is the District Communications Officer for the organization, and Daniel's mother Naomi WB6OHW, brother Brian N6FKG, and sister Mari KA6PTV are all members.

Eagle Droppings

HAVE YOU SEEN the latest catalog from Innovations? They're one of those companies that offer high-tech goodies like wine computers and 127-function watches. On page 38 of the catalog, right between Wet Tunes the Shower Radio and the Bionic Ear, is a little item called the Eagle 1 Professional Transceiver. "Not a toy or Citizens Band walkie-talkie. FCC approved, license information included. The Eagle 1 packs 200 milliwatts of output power for clear, sharp transmissions up to 4 miles. Useful in warehouses, farms, and factories. Choice of 3 crystal-controlled channels within 10-MHz band for privacy (one crystal supplied with each unit)."

Brent Cordes AE6R checked with Samhill Corp., the manufacturer, and discovered that the crystal supplied with each unit is for 446.000 MHz, the national calling frequency for the amateur 440-MHz band! The other two channels are 446.200 and 445.800. I telephoned Samhill in New York and asked what sort of license was required to operate the Eagle 1. "Oh, amateur," was the reply. I can see it now. . . thousands of yuppies buying chic little HTs, only to find a note in the box telling them that they can't use the radio until they learn Morse code and get an amateur license! We've dropped Innovations a polite note, and will let you know what happens.

Pubs Merge

BOB GROVE, Editor of *Monitoring Times*, and Larry Miller, Editor of *International Radio* (formerly *Shortwave Guide*), have announced plans to merge their publications. Starting with the July, 1986, issue, the new *Monitoring Times* will feature an expanded 60-page format and improved laser printing. A one-year subscription is $14, available from 140 Dog Branch Road, PO Box 98, Brasstown NC 28902; (704)-837-9200.

Expo '86

THIRTEEN MILLION VISITORS to Canada's World's Fair of Transportation and Communication will be exposed to the amateur radio virus, thanks to the members of the VE7EXPO Amateur Radio Society. The all-volunteer effort will feature SSB, CW, RTTY, AMTOR, packet, FM, ATV, and SSTV at five operating positions—two for HF and one each for packet, OSCAR, and VHF/UHF. The Exposition, which will run through October 13th, is housed on the Canada Pavilion, "anchored" in Vancouver harbor. The ham station, using special call VE7EXPO, will operate from 10 a.m. to 10 p.m. each day. Local repeaters (146.94, 224.30, and 443.525 MHz) will be monitored to provide directions and assistance to visiting amateurs. If you would like to work from the station, or if your club would like to come up as a group, contact the VE7EXPO Amateur Radio Society at 202-13640 67 Avenue, Surrey, British Columbia Canada V3W 6X5.

Glowing Report

73 INTERNATIONAL correspondent Rudolf Karaba OK3KFO sent us the results of a UHF aurora marathon recently completed in the Soviet Union. For two years, Soviet experimenters have participated in a competition designed to examine UHF aurora propagation. The top three single-op stations are UA3BMJ with 155 QSOs and 5,442 points, UR2RQ with 139/3,795, and UA9XQ with 149/3,159. The top club station is UZ9CXM with 23 QSOs, and the top SWL is UA3-142-198 with 9 reports.

No Note Needed

THE FCC, in a letter to the PHD Amateur Radio Club of Missouri, said that no doctor's statement is required when special amateur testing procedures are needed due to an applicant's physical disability. The statement was necessary under the old testing system when an applicant was unable to travel to an FCC testing site, but the requirement was not carried over to the new volunteer testing program.

4X4 Foray

A TWO-WEEK TRIP to the Holy Lands is being arranged by the Chaverim, an international group dedicated to fostering goodwill among Jewish hams and their friends. The tour will depart from J.F.K. International Airport on Monday, October 27th, and will return to the States on Monday, November 10th. The group will visit Muslim, Jewish, and Christian shrines and will have the opportunity to operate from 4X4 during its stay. There also will be meetings with the Israeli Amateur Radio Club and the Quarter Century Wireless Association. Space is limited, so contact Bill Soble W3QXT, 9357 Hoff Street, Philadelphia PA 19115; (215)-676-6769.

Motorola Morgue

HERE'S A GREAT OPPORTUNITY to get rid of all that junk in your shack (sorry, I meant "valuable communication equipment"). Don Parker, Motorola's Branch Manager for Alaska, is the curator of the new Museum of Early Two-Way Radio Equipment in Anchorage. Don has already gathered a number of vintage VHF/UHF radios, but is looking for more. If you think you might have something that belongs in a museum, get in touch with Don at Motorola, Inc., 5333 Fairbanks Street, Suite lbsgn1, Anchorage AK 99502, or call (907)-562-2111.

Write-In Vote

THIS MONTH YOU'LL FIND a special Feedback card next to page 80. Use it to rate the articles and columns in this month's *73*. When all of the votes are in, we'll award a free one-year subscription (or extension) to the person whose name is on the card we draw out of a hat. While you're filling things out, take a second to complete the Product Report Card, too. In July we will begin publishing a running tally of your favorite radios. . . or least-favorite, for that matter.

Log Jam

LOGS FROM THE DP0SL Hams-In-Space mission of last year have been released. An automatic logging machine aboard the shuttle captured the following U.S. callsigns: AA6G, AJ5L, K1PXE, K6CO, K6NLP, K6RTC, K7PYK, KA0NVT, KA0DO, KA1DUX, KA2RBX, KA6CR, KA7SJP, KB4CRT, KB6FFJ, KB7RV, KC7EM, KD5RO, KD6PY, KD6WG, KD7AW, KG6GF, KG6KO, KG6LC, N1DBB, N2BKT, N3FL, N6CAV, N6FF, N6GVP, N6IDN, N6RW, N7GDW, N7ZL, N9AB, NA6E, ND2X/5, NF6S, NK6K, NN0V, W0BPP, W1HH, W1NU, W2JNO, W3IP, W3PM, W4BE, W4MOP, W5AQQ, W5CBT, W5EBH, W5HQQ, W5HUQ, W5RRR, W5VY, W5ZIB, W6KH, W6MFO, W7MCU, W7OHF, W7QLC, W7US, W9ODI, WA0RCX, WA1FCK, WA1OMM, WA3HUP, WA3WBU, WA4BUS, WA5NOM, WA5RCL, WA5ZIB, WA6YBT, WA7GCS, WB4KXB, WB5BSH, WB5GLD, WB7AYU, WB5LBJ/DU6, WB7OHF, WB8OTH, WD4AHZ, WD4BCS, WD4NAE, WD4PQN, WD5EZR, and WD9IIC.

QSL

That's all for this month. Thanks to *Westlink*, the *W5YI Report*, *Amateur Satellite Report*, Tad Cook KT7H, Robert Smits VE7EMD, and the *DX'ers Magazine* for help with this month's column. Send your news and photos to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: QRX.

Canada Place, site of the Canada Pavilion and special-event station VE7EXPO.

NEVER SAY DIE

from page 4

We stay in the best hotels and get great breakfasts every morning as part of the tour package. The tour includes air fares, land transportation, airport taxes, and so on. The ham DXpedition will include at least one hamfest dinner in each city. Chang also organizes reasonably priced dinner parties for those interested in trying local foods—such as the delicious Mongolian Barbeque in Taipei. Or perhaps, by the time you get to incredible Hong Kong, you'll be ready for a Mexican dinner. That was my choice last October—dragging along a young ham, Chris Peterson KB9YT, and Rod McKuen (the poet), going to the restaurant via the Start Ferry, then a ride on a 75-year-old trolley car. You won't forget a trip around Hong Kong like that—especially at night. We went back to our hotel on the new ultramodern subway.

They've got a 2m repeater in Hong Kong, so we'll all be able to keep in touch from anywhere in the colony. Bob and I were talking about bringing a portable repeater to Taipei, but we don't know whether Tim Chen BV1A will be able to get it okayed or not. It'd be fun, if we could swing it. We might be able to do that in Seoul, too. I got a license there a few years ago as HL9WG and worked all over the city with my HT via a repeater run by Army MARS. Everyone should bring an HT, naturally.

The DXpedition will take about ten days, which almost everyone should be able to finagle.

I should be satisfied with a DXpedition to Korea, Taiwan, and Hong Kong, but I wondered if, as long as we're in the area anyway, you might not want to take just a few more days and make it not just a trip you'll never forget, but one your friends will never forget either. My sneaky plan is to take those with the time and guts on from Hong Kong to Sabah 9M6, Brunei V85, and Sarawak 9M8.

I made this trip three years ago and it was one of the most interesting I've ever made. Along the Borneo north coast is Kota Kinabalu, Sabah, where we'll stay at the Kinabalu Hyatt. KK, as they call it, is a lovely, fascinating town. The hams are incredibly friendly. Until you've gotten on the air from Sabah, you don't know what a pileup really is from the DX end.

The next stop is Bandar-Seri-Begawan, the capital of Brunei—the wealthiest country per capita in the world. We'll stay at the Brunei Sheraton. The hams there are also ultra-friendly. This is the country where people are able to get interest-free loans from the government for cars and houses. The Sultan is the richest man in the world. I wonder if he'll shake hands with us—he might if we have a good-sized group.

In Kuching, the capital of Sarawak, we'll be staying at the new Hilton. On my last trip I got on the air and had a ball. I also made a side trip up into the hills to visit a long-house—a whole village built on stilts, including the sidewalks. There were still skulls hanging from the days, just a generation ago, when these people were still head hunters.

The whole trip—Seoul, Taipei, Hong Kong, Kota Kinabalu, Bandar-Seri-Begawan, Kuching—will take twenty days—about three weeks for an experience you'll never forget. If you go for it, Bob and I have an eye on getting you to China and Macao next year—and probably to Singapore and Bangkok in 1988—unless you'd like to get up to see Father Moran in Nepal and see what it's like to operate from 9N1MM. Yep, I've done that, too. I've operated from all those places. . . ho hum. . . yawn.

Of course it's always possible that amateur radio has been so decimated by its lack of growth for the last 23 years that there aren't enough adventurous spirits left to make a DXpedition like this feasible.

Take a look at your calendar and see if you can get away from October 5th to 16th for the three-country DXpedition—or until October 25th for the six-country DXpedition. The costs aren't firm yet, but should run around $3,000 for the three countries and $5,000 for the six countries.

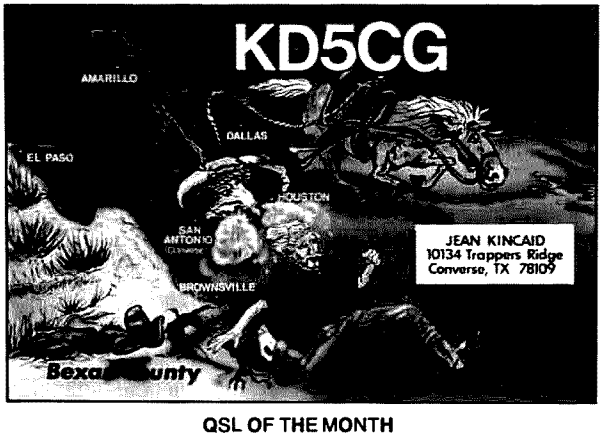
If you've got enough left to bring your wife, I guarantee she'll enjoy it. There are plenty of things to see and a lot of shopping to do. You probably already know about buying electronic gadgets in Hong Kong—by far the cheapest place in the world for 'em. HK is also a great place for clothes—providing you manage to get past the tailor in the hotel in Taipei where most of the group this last trip bought $150 custom-made suits (I bought two). Custom-made shirts are $10. You've seen the Seoul bargain fur ads in many American magazines.

In Sarawak you get some great batik paintings and batik shirts. I like the batik shirt I bought in Kuching so much I wear it just about all summer. Each country has interesting things to buy. The prices are surprisingly low—except in Manila where they are much, much lower.

Tell your wives that Sherry was with me on the trip and loved every minute of it. She will never forget our sitting at dusk by the Sarawak River having a "steamboat" dinner—all sorts of meats and vegetables you dip in boiling broth and cook at the table. It's a lot like shabu-shabu, if you've had that.

We also won't forget the short intense rain shower which dumped maybe four inches of water in an hour and then went away as quickly as it came. Sure, these Borneo countries are only about a hundred miles from the equator, but they're comfortable, running around 82–85 degrees year round. Don't bring your heavy coats—just a raincoat or umbrella for that occasional shower.

Let's see, I didn't mention a visit to the Korean Village, just outside Seoul—you'll need lots of film for this. It's a recreated old Korean village, showing how people used to live. There are plenty of food vendors and their food is superb—cooked while you watch.



In Taipei you'll want to allow some time to see their incredible museum—and maybe, if you have the stomach for it, a trip to Snake Alley. Yecch. You'll certainly want to try a Wendy's hamburger at the Wendy's next to the hotel in Taipei and the one at Etweon in Seoul—the only Wendy's in the world I know of with hookers sitting around the tables looking for business. Yep, they serve Frosties there too. If you get hooked on Wendy's, there's a nice one in Hong Kong now, too, complete with salad bar. Lordy! It's all there, McDonalds, Pizza Hut, Kentucky Fried—even Chuck E Cheese's Pizza Time Theatre. Of course just down the street you can get a great Indonesian ristofle.

I'm trying to arrange to have some QSL cards we can take along with us—if I can get my print shop in gear. If you sign up in time we'll have your QSL cards for the trip—showing your six-country DXpedition on a map.

You'll have to make a decision on this early so Bob will be able to send a copy of your ham license to each of the seven countries involved and get the paper work done. These government bureaucrats don't rush for anyone, so get me a $1,000 down payment for the trip and eight copies of your ham license.

I am planning on personally escorting the DXpedition—so I'll be able to give you inside info on where to go, what to see, what to shop for, and what to do. Be warned that I also talk a blue streak and got surly the only time anyone out-talked me.

I have this peculiar problem—when I find something which is fun I have an urge to share my fun with as many people as possible. DX-

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, WGE Center, 70 Rte. 202 N., Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

peditioning to Asia is just about the last word for a ham, so I'm pushing you to take the egg money and come with us this October.

If I don't get at least 50 DXpeditioners signed up by June 30th I'll have to just go by myself and look for you on 20m, eating your heart out.

Young hams, if there are any, shouldn't waste their money on a house or a car—they should invest it in the memory of a lifetime. Retired hams should dig into the sugar tin and get on this DXpedition while they still have some life left. Remember, the average life span of men these days is 72—which means that by the time you're 72 half your friends are dead and the other half are too sick to travel anymore.

So, as I asked in the beginning, are you ready to come with me—sit down at a rig in a rare country and face the pileups? Write to me—Wayne Green W2NSD/1, DXpedition '86, WGE Center, Peterborough NH 03458 USA, so we can get moving.

THOSE FOUR-LETTER WORDS

Mercy me, the good old days are back—I've just had an indignant letter complaining about my using four-letter words in my editorial—words like hell and damn. Well, the letter got me to thinking, so it wasn't completely wasted. Oh, as far as getting me to change my writing vocabulary, it was a waste. The purpose of words is to convey ideas, so I'm going to use what I feel are the appropriate words to express my ideas. When I'm expressing anger or exasperation, I'll be using words which convey my feelings—strong words.

There's a big difference in my mind between effectively communicating ideas and gratuitous cursing. Having spent several years in the Navy, I'm quite at home with everything our language has to offer in so-called dirty words.

Which brings me to profanity over the air—of which I am not a big fan. In case you haven't noticed, the FCC has backed off on this. Every attempt to keep broadcasters "clean" has resulted in our courts backing free speech. The end result is that legally, the last I heard, you can use any of the four-letter words you like.

Before you trot out your version of Navy language and bray it on 75m, let's think about this. When I hear someone using foul language, I hardly think s/he is very intelligent. We're just not used to hearing educated people talk gutter language. Note the term—gutter. That means the lowest possible class—gutter people.

Just as we dress for the impression it makes on other people—dress for success, as it were—we also use language for the impression it makes. People *do* judge you by your clothes when they see you. Conversely, you are showing people who you are by the way you dress. If you are a low-class bum you'll dress that way.

When we hear someone over the air the only way we have to judge that person is by the language s/he uses. We judge by their vocabulary, their accent, and the way they express themselves. Have you ever made a tape of your voice making a ham contact and then listened to it critically—listened as if this were someone else you were judging purely by what you're hearing? Tape recorders are cheap thse days—in fact, most of you have at least one around. Try taping yourself for an hour and see how you come out when you judge yourself.

We have a far from classless society. Indeed, class is something most of us are concerned with a good deal of the time. We judge people by how they dress and talk when we meet them. Are they above or below us in class? Oh, it's not usually a conscious thing, but we judge people and treat them accordingly.

Class has been fairly well described in many books. Vance Packard did a fine job of this a generation ago. Class is ingrained—it shows clearly in your clothes, car, house, furnishings, speech, recreation, the food you eat and drink, and your work. There are so many lifetime training factors involved that few people are able to change class. We're familiar with lower-class people who've gotten rich—the "Beverly Hillbillies" syndrome. We make fun of them.

When we hear fellow hams talking we can't help but look for clues as to class. We get 'em from their language. If we hear four-letter words—or even that dread 13-letter word—we know what you are. Remember, you only have one chance to make a good first impression—and when you're on

LETTERS

WIRE ON FIRE

I found that the W3MT antenna bridge described in the April, 1986, issue does indeed put more fire in the wire. Running a mere two candlepower input, my CW signal is reported to have pegged the S-meter at ZS6NN. Amateur radio needs more revolutionary circuits like this one.

Howard Sahl WB8IWN
Lakewood CO

STONE STONER

I was in total shock and dismay over your support of RM-5241 (QRX, March, 1986) to take away the upper two MHz of our six-meter band for the creation of Don Stoner's Public Digital Radio Service (PDRS). Stoner's contention that "less than 1,000 are active on the band" is preposterous! The 2,500 members of the Six Meter International Radio Klub (SMIRK) and the approximately 300 repeaters on six (there were slightly over 50 in 1978) are evidence of this. There are a sizeable number of users of six in the club to which I belong (Goddard ARC) and if my calculations are correct there are *tens* of thousands of six-meter users. My interest in amateur radio began on six meters as a teenager in the middle seventies, primarily because of the varied propagation one can experience on the band. Six got me into amateur radio, and it can continue to lure others, particularly with the sunspot cycle headed upward.

Six is healthy, and use of it is growing. Recent access to the band by the British, with other European countries soon to follow, can only accelerate this growth. While there may be a lot of hams who don't use six, there are many of us out here who do. No, six meters is not dead; there are a lot of us out here who enjoy it, thank you. We intend to keep it that way.

Richard Penc NE2J
Laurel MD

Come on, Richard, there are barely tens of thousands of hams on the air to begin with, and you want me to believe that most of them are on six meters? I don't buy it. It seems to me that the current (and projected) level of activity could be handled in a 2-MHz-wide band. I think the overall benefit to ham radio from a PDRS outweighs the loss of a few MHz of spectrum.—KW1O.

CAN SCAN

I totally agree with the comment about the ICOM IC-02AT in the February issue. I bought mine a year ago and have found it to be an extremely nice radio, but its scanning speed leaves much to be desired! With today's technology I can't understand why it scans so slowly. I've noticed the speed of my friend's Kewood HT; it greatly outperforms the 02AT in the scanning department. Could you do an article on how to speed it up?

Chris Suleske N4LZG
Stafford VA

While you're waiting for the speed-up mod, check out the article by AL7DS in this issue to find out how to cover 144 to 165 MHz on your 02AT.—Ed.

DSB NEEDED

Glad to see Wayne back in the arena, handling the flaming sword in defense of the radio amateur!

AM is through, we must recognize, but SSB is very difficult to home-brew, especially outside the United States, due to troubles finding crystal filters and so on. I think that double-sideband (DSB) might be the answer we are looking for. It's much easier to design than SSB, with no crystal filters—beginners could have their fun again! What the world needs is an easy-to-build transceiver—make it DSB!

Carlos Vianna Carneiro PY1CC
Rio de Janeiro, Brazil

Let's forget the PDRS on six meters and give 52–54 MHz to the AMers and DSBers. . . they can QRM each other as much as they like, and I bet nobody would miss them on HF.—KW1O.

THE GREAT EXCLUDER

I usually agree with you concerning amateur radio. We need to get the rest of our hobby's members to open their eyes and ears and put their brains into gear and look into the future of our pastime.

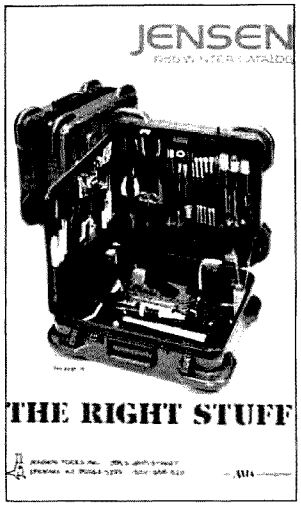
I am a retired Air Force flyer. I have been teaching in the electronics program at East Tennessee State University for the past few years and have watched many a potential ham go away, probably never to return. We offer a course in ham radio, for one semester-hour credit. The student must earn a Novice ticket and make contacts on the university radio station. The course is conducted by K4SE. The results have been so-so.

I have conducted several Novice classes over the past few years and, to tell the truth, I feel that most of it has been a waste of time. Several people have obtained their licenses, but to my knowledge only one has used it. He has upgraded and is active. The rest, put bluntly, have no desire to use the code and don't even give it a try.

We worry that we will let the wrong element into ham radio if we relax and drop the great excluder, CW. I have news for the worry warts: We are doing what we want to avoid by keeping the code as an entry requirement. It is a common practice for one person in a group to go get a legit Novice ticket, then upgrade to General and then get all his friends into the hobby via the Novice route. They are usually into electronics and computers and have no trouble getting a Tech. ticket. Most of them make good hams. It's a shame we force them to be unethical to get into our hobby.

I hope you can get back on the bandwagon and lead us on. We need to badger the ARRL and FCC until we get the no-code through. If we don't, I'm afraid our hobby is doomed.

Why did I become a ham? It sure wasn't to communicate! I wanted to be able to fly my model airplanes and be able to conduct legal on-the-air experiments with radio control. Involvement with hamming in the traditional sense came later. I was involved with emergency communications in the early 60s when a hurricane ripped up the outer banks area of North Carolina. AM on a BC-610 from the MARS station. I don't get on the air very much even though I have 160–2 all-mode capability. When I do it I'm usually working some Novice. I get a thrill out of being the first contact for a new ham.



In teaching we try to develop a rationale for learning from the point of view of the student. If the student does not have a good reason for learning, he will not learn much. If he does have, you can't help him enough. We must find a reason why Joe Ham in the United States should want the no-code ticket and the thousands of new hams it would attract.

I have not heard much discussion about the influence that the Japanese no-code ticket had on the availability of ham gear in the United States, but I'll bet not many of us have thought about it. More hams will bring more crowding on the bands. Yes. But it will also bring more makers into the equipment markets and more and better equipment for us to buy. When we develop the newer techniques such as spread spectrum, as we did with SSB, the congestion will disappear. The new people will bring with them new ideas and we will all benefit.

One last bit: I teach a course called electronic circuit fabrication. The typical student comes into the course with the usual fears of not being able to do it, and then after a few successful laboratory experiences, during which skills such as soldering, wire-wrapping, parts testing, and such are introduced, the student becomes enthusiastic about it. We go from a schematic to a completed project that must include a PCB. When the semester is over, we have a group that has found the joy of making something that works and is ready to give something else a try. Too bad we exclude them from ham radio with Morse code. If we don't make room for them in our bands, someone else will! Remember 11 meters?

Donald H Lettrell W4VBH
Bluff City TN

NEW PRODUCTS

Free tool catalog available from Jensen.

NEW JENSEN CATALOG

Jensen Tools, Inc., has released its latest catalog featuring many additions to the Jensen line of tools, tool kits, and test equipment.

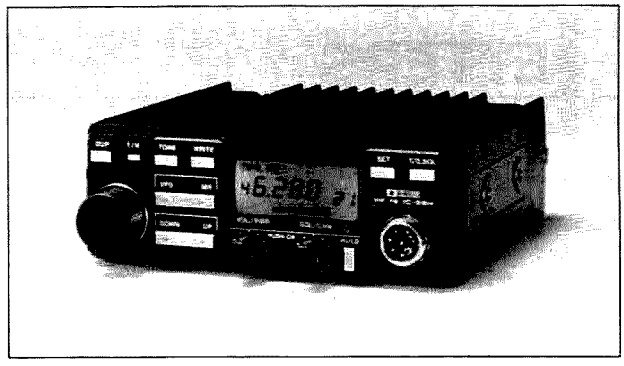
The 82-page catalog is available free from *Jensen Tools, Inc., 7815 S. 46th Street, Phoenix AZ 85044; (602)-968-6241.* Reader Service number 157.

KALGLO CONDITIONED UPS

Kalglo Electronics has added a new standby uninterruptible power supply to their Aegis™ line of power-conditioning equipment. The model LS250 Line-Saver-SREGTR uses pulse-width modulation to regulate the 250-Watt rms ac output for greater efficiency under various load conditions. The PWM ac output also increases battery efficiency to extend backup time: 5–10 minutes at full load, 20–25 minutes at half load, and 35–40 minutes at one-third load.

The unit comes with an internal 12-V sealed rechargeable battery, two voltage-surge-protected ac outlets, and audible and visual power failure indicators. The suggested retail price is $549.

For more information, please contact *Kalglo Electronics Company, Inc., Dept. CP, 6584 Ruch Rd. E. Allen Twp., Bethlehem PA 18017; (215)-837-0700.* Reader Service number 159.



LOW-TEMP ALUMINUM BRAZING ROD

Medford Specialized Services markets an aluminum brazing rod for repairing and welding aluminum, copper, and brass joints. The rod's low melting point (732 degrees) makes it easy to use with a propane torch. Low-resistance joints may be formed on antennas, tank circuits, and matching networks as simply as soldering.

For further details, contact *MSS Wonder Rods, N3401 Castle Rd., Medford WI 54451.* Reader Service number 153.

ICOM HIGH-POWER 2M MOBILES

ICOM has announced two new packet-compatible 2m mobile rigs, the IC-28A (25 Watts) and the IC-28H (45 Watts). Both radios are small, only 5-1/4″ x 5-1/2″ x 2″ (the IC-28H is 7-1/4″ deep). They feature a large liquid-crystal display with automatic dimming, wideband (138–174-MHz) coverage for MARS and CAP operation, 21 memory channels, and band or memory scanning.

ICOM's IC-28H 45-Watt 2m mobile transceiver.

For more information, contact *ICOM America, Inc., PO Box C-90029, Bellevue WA 98009-9029.* Reader Service number 152.

OVONIC SILENT GENERATOR

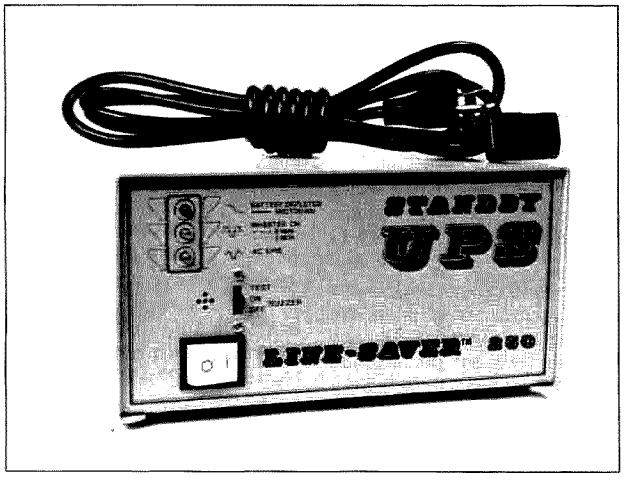
Ovonic ThermoElectric Company, a division of Energy Conservation Devices, Inc., is now marketing the Compact Silent Generator. This lightweight, silent, solid-state generator obtains its energy from any source of heat and can produce up to 6 Watts of dc at 9 volts or up to 5 Watts at 6 or 12 volts. The CSG can directly power light loads or be used to charge external batteries.

For complete information, write or call *Ovonic ThermoElectric Company, 1864 Northwood, Troy MI 48084; (313)-362-3140.* Reader Service number 154.

ACTICON MINI RS-232 PORT

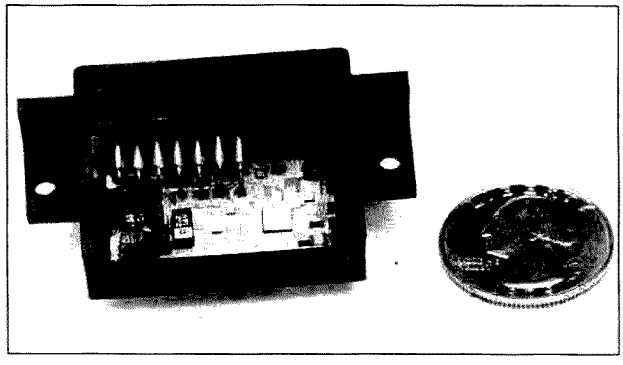
Rapitech Systems, Inc., has developed a DB-25 connector which includes a complete RS-232 communication circuit. The Acticon™ connector was designed to free up space on computer circuit boards by placing all of the hardware necessary for RS-232 communications inside the DB-25.

For complete details, contact *Rapitech Systems, Inc., 75 Montebello Rd., Suffern NY 10901.* Reader Service number 156.



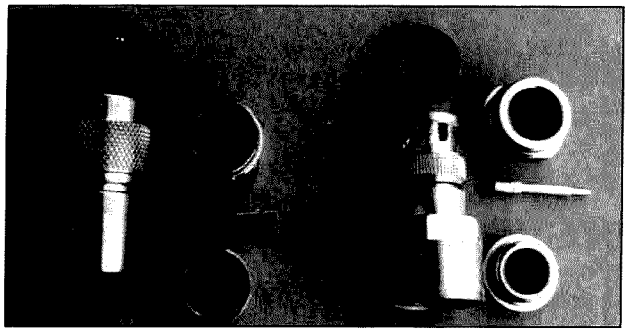
ETRON RF NOTES 3

Rf Notes 3, Volume 1 is a new software package from Etron Enterprises which aids in the design of Butterworth-response filters to the seventh order. Based on network modeling, the program designs low-pass, high-pass, band-pass, and band-reject filters as a function of input/output impedance ratios and user-defined input parameters. The output of the program is a schematic diagram labeled with circuit constants.



Rf Notes 3, Volume 1 is available for IBM DOS 2.1; for further details contact *Etron Rf Enterprises, PO Box 4042, Diamond Bar CA 91765; (714)-594-8741.* Reader Service number 158.

LARSEN 450-MHZ KULGLASS™ ANTENNA



Larsen Electronics has announced the model KG-450 on-

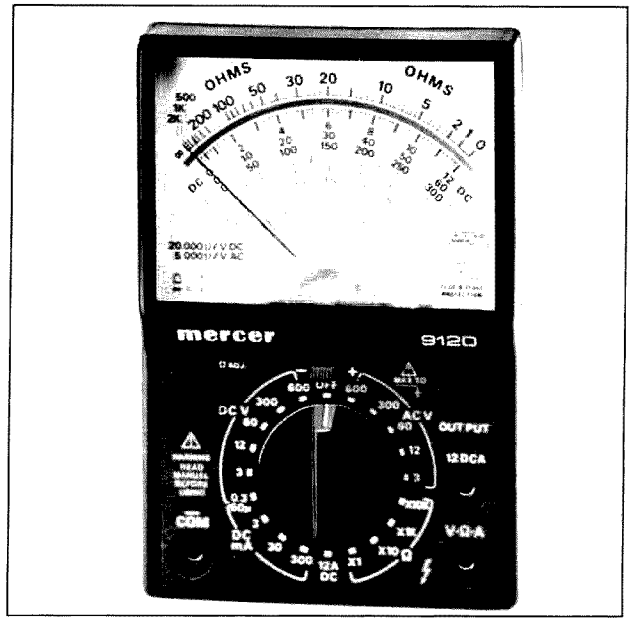
The LS250 standby UPS from Kalglo Electronics.

The Acticon active connector from Rapitech Systems.

Nemal connectors for Belden 9913 and 8214 cables.

glass antenna for the 450–512-MHz range. The KG-450 is a half-wave, unity-gain element without a ground plane, and offers up to 2.4 dB gain in most mobile installations. The antenna is tuned by cutting the whip according to a chart provided by Larsen. The antenna kit includes 14 feet of RG-58A/U low-loss coax.

For more details, write or call *Larsen Electronics, PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 161.



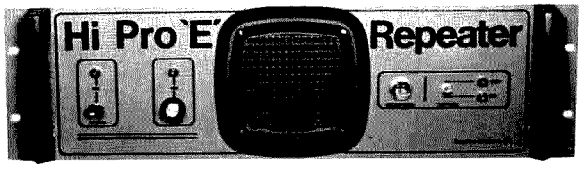
NEMAL CONNECTORS

Nemal Electronics has introduced a new line of connectors designed to fit Belden 9913 and 8214 style cables. The connectors are available in both type-N and BNC and accommodate a 9-1/2-to-11-gauge center conductor. Both styles meet MIL-C-39012 specs and incorporate silver-plated contacts and Teflon™ insulation.

For more information, contact *Nemal Electronics International, 12240 NE 14th Avenue, North Miami FL 33161; (305)-893-3924.* Reader Service number 155.

MERCER VOM

Mercer Electronics, a division of Simpson Electric Co., has introduced the model 9120 VOM. The new instrument features 25 ranges (including dB), 20,000 Ohms/volt dc sensitivity, 5,000 Ohms/volt ac sensitivity, and a frequency response of 100 kHz on the 3-, 12-, and 60-volt ac ranges. The model 9120 will measure up to 12 Amps dc.



The Mercer model 9120 VOM.

For additional information on the model 9120 VOM, contact *Mercer Electronics, 859 Dundee Ave., Elgin IL 60120; (312)-697-2265.* Reader Service number 160.

Hi Pro 'E'

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.

• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.

• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

Head-to-Head: Kenwood's TS-811A versus ICOM's IC-471A

by Peter H. Putman KT2B

ICOM America, Inc.
2380-116th Avenue NE
Bellevue WA 98004
IC-471A—$799

Trio-Kenwood Communications
1111 West Walnut Street
Compton CA 90220
TS-811A—$899

Here's the dilemma: You'd like to get on the 70-cm band, and in a big way. You've set your sights on weak-signal operation, ATV, OSCAR, and even some FM repeater and simplex operation. Then you read in a VHF column that "nothing beats using a transverter with your multimode HF transceiver." Sounds Good! Then you discover that using a transverter with your HF radio at best yields only about 4 MHz of the band to play with in the vicinity of 432 to 436 MHz. Hey, that won't work at all!

So you peruse the catalogs and come across the wonderous 70-cm multimodes various manufacturers (all Japanese) make and see that they'll give you what the transverter scheme won't—full band coverage and all modes. A quick call to the local authorized distributor and soon you're the proud possessor of one of these beauties. Bet it set you back a piece of change, too!

Now you're busy chasing OSCAR contacts and tripping repeaters all over the area, wondering why anyone would prefer the transverter route. Good question, and among those which this review will try to answer!

For this review, I obtained two off-the-shelf 70-cm multimodes from local amateurs, to ensure that what I evaluated is what you'd be likely to buy. I wasn't able to obtain the Yaesu FT-726 with 70-cm module, but at least you'll get an idea how the state-of-the-art from ICOM and Kenwood compare to your present setup—not to mention each other! No doubt about it, these radios will set you back a few dollars. Are they worth it? Let's find out.

A Comparison of Features

The ICOM 471A lists for $799. For this, you get 25 Watts rf output, dual vfo's, 32 independent programmable memories, and three different scanning modes. The Kenwood TS-811A lists for $899. This buys you 25 Watts rf output, dual vfo's, 40 independent programmable memories, and three different scanning modes. Pretty close so far.

Both radios offer USB, LSB, CW, and FM operation over the 430–450-MHz band. Both have continuously adjustable power output. Both are capable of ac operation (an ac power supply is standard on the TS-811A, whereas on the IC-471A it's an option) and can use "scanning" microphones for remote tuning. That's where the similarity ends.

ICOM and Kenwood have, in their own peculiar ways, included and excluded from these radios certain features that you might either wish to have or have no use for whatsoever! In many cases, the feature present on one radio is missing or unavailable on the other. Perhaps the best way to show this is with Table 1.

Obviously, there's a difference of opinion here regarding just what the 70-cm operator needs in a multimode transceiver. It makes it more difficult to review the units from a comparison standpoint, as well! When possible, I'll touch on how well these features worked for the particular radio under test.

Photo A is a front view of the two radios. They're comparable in size, with the ICOM being slightly larger. Both displays are easy to read and contain a multitude of information regarding operating mode, scan mode, RIT position, simplex/duplex operation, and tuning speed on the vfo. Both employ push-button function and mode selection.

Here's where I make my first subjective evaluation: The TS-811A's multifunction buttons make its front panel somewhat confusing, and it takes a second to find your way around the rig. On the other hand, the IC-471A is very user-friendly, and anyone could begin to use this radio right out of the box without referring to the manual.

Speaking of manuals: I've gotten quite used to the strange English that peeks through Japanese manuals on occasion. However, there is no excuse for the spelling errors in the

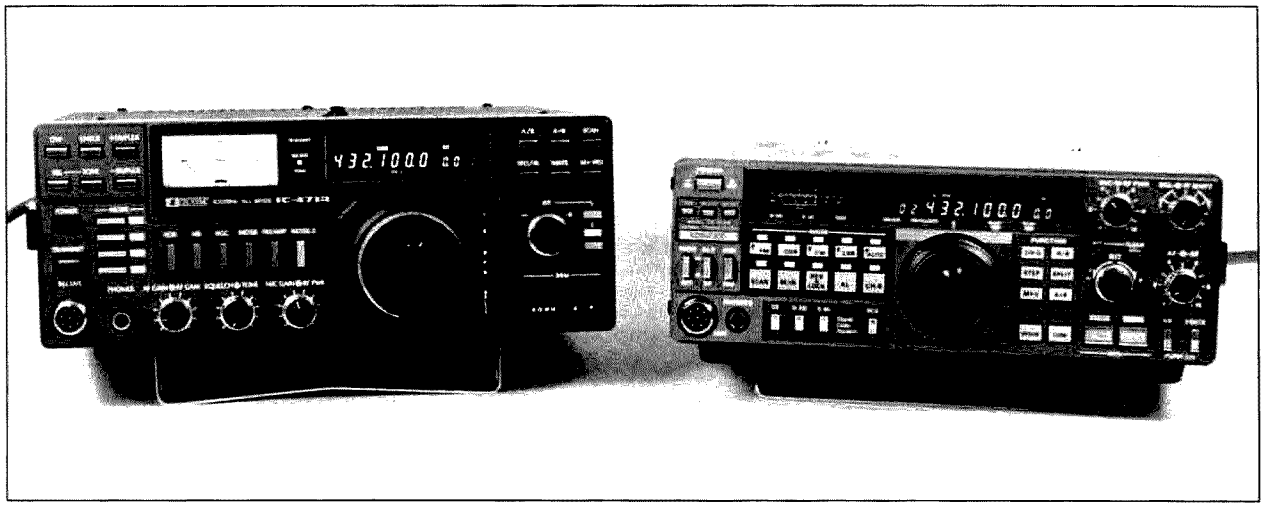

Photo A. The ICOM IC-471A and Kenwood TS-811A 430-MHz transceivers.

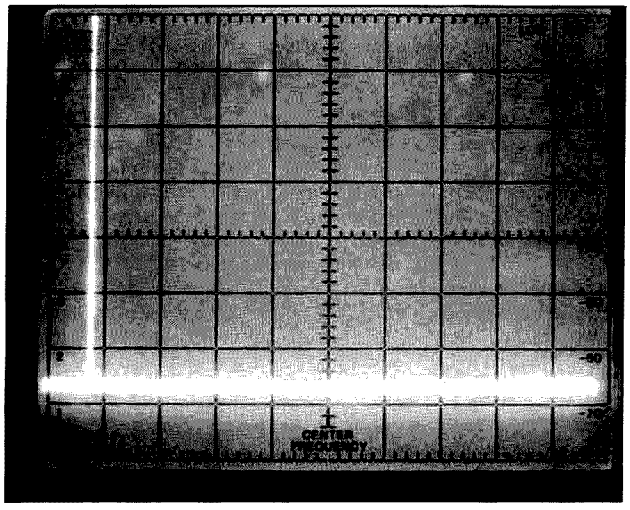

Photo B. Spectral display of the TS-811A running 25 Watts at 432.100 MHz. The second harmonic is down more than 70 dB.

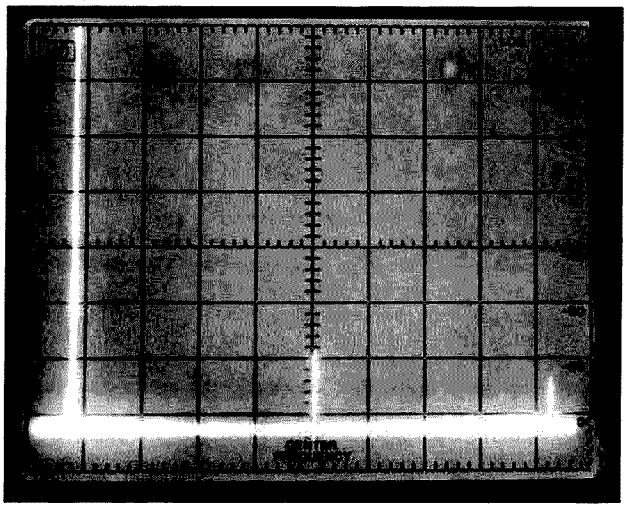

Photo C. Spectral display of the IC-471A running 25 Watts at 432.100 MHz. The second harmonic is down 60 dB.

TS-811A manual. Come on, guys! "Microporcessor?" Both manuals are fairly thorough, to their credit. The Kenwood manual is quite detailed regarding the front-panel controls and the use of the vfo's, memories, and scan features. The ICOM is equally thorough with its explanation of the front-panel controls, but it uses fewer words to get the job done.

Both radios have the complement of bells and whistles you'd expect for the price. The ICOM's bells and whistles, however, have more practical value and Kenwood's are more hi-tech for technology's sake. (I'll elaborate on that momentarily.) Kenwood has also included its new DCS (Digital Coded Squelch) system, which is becoming standard equipment on its VHF/UHF radios. Since it didn't compare to anything on the ICOM, I chose not to test and review it.

The Kenwood TS-811A

Okay, on to the controls! Starting with the Kenwood, one feature I found downright clever is the switch marked CH.Q. When you press this switch, the vfo dial steps in 5-kHz increments with a positive detent feedback through the dial—it really clicks with each step! Apparently, this is accomplished with a solenoid system, as you hear a rather loud relay "click" when you press the switch. With the switch out, the vfo dial tunes silky smooth in 10-Hz increments. I've never seen anything like this before on any radio!

The FM, USB, LSB, and CW push-buttons provide for more multimode selection. In addition, the Morse verification through the speaker of the push-button selected is useful if you're not looking at the radio directly. Next to this control is one marked AUTO, which automatically selects the mode of transmission depending on where you are in the band. Only problem is it's based on some sort of Japanese band plan that doesn't jive with ours, at least below the OSCAR subbands, so this control is useless and can be ignored.

Below these buttons are controls for SCAN start/stop; M.IN to save memories; REV & LOCK to lock up the dial and provide for reversed offsets in memory channels 36, 37, and 38; AL to turn on/off the channel 1 priority circuit alert; and CH.S to operate the channel-select position for dialing up memories. Phew!

On the right of the vfo knob are controls for the previously mentioned CH.Q function, A/B to select the two vfo's, STEP to select tuning rate, SPLIT to split the vfo's, M>V to transfer data from the selected memory to the vfo, and A=B to reset the two vfo's to each other. Below these are controls to select either vfo or memory position and a control marked COM, which is for a preset frequency of 433.000 MHz (apparently some sort of simplex net frequency in Japan). You can reprogram this if necessary.

The complement of controls is rounded out by a continuously variable RIT control, which a second switch from the front panel can cancel. RIT excursions are in the range of 9.9 kHz either side of center frequency. Also found are MIC and RF PWR controls, IF SHIFT, SQL for squelch, noise blanker, AF gain, RF gain, Up/Down 1-MHz frequency selection, and VOICE for an optional VS-1 voice synthesizer.

On the far left, two of the three tiny switches select repeater offsets and subaudible tones (with the optional TU-5 board installed); the other activates the tone circuit. Below these are three larger switches for speech processing, ALC meter display, and ACC—which activates a rear-panel connector with dry-contact closures rated at 0.2 Amps. Enough switches for you? I thought so.

And, would you believe with all that there's no front-panel transmit/receive switch? Instead, you have to either insert a subminiature plug and switch into the rear-panel jack marked ST BY or use the PTT switch on the microphone. (Why do you need a separate T/R switch? How about when you're checking swr on antenna lines! Since the TS-811A has no VOX circuit, you need to use the ST BY circuit to switch to transmit when operating CW. A front-panel switch would have been more convenient!)

Kenwood receives another bad grade for using a "UHF" SO-239 connector instead of the standard type-N at this frequency. Come on, Kenwood. Type-N connectors aren't that hard to make up. At least ICOM doesn't think so, as they did use a type-N fitting on their antenna connection. (But I'm getting ahead of myself!) Other rear-panel connections include external speaker, Key jack for a CW key, ACC 1 for a computer interface, ACC 2 for an external RTTY interface (this wasn't quite ex-

plained in the manual), and finally, ac and dc power connections.

As I said earlier, the TS-811A comes with a power supply as standard equipment. One note here: The owner of this radio, Bill DiCarlo KA2QEP, mentioned that the area around the power supply gets quite hot when it's been on for awhile.

I didn't notice that the transformer became dangerously hot over a two-hour period, but it did get very warm, so I would recommend adequate ventilation when using the internal supply. If the unit must be in a confined area, use a muffin fan to keep cool air flowing through the supply. Bill mentioned that other TS-811A users mentioned this condition as well when he worked them on OSCAR, so apparently the problem is not isolated.

The ICOM IC-471A

Enough of Kenwood. Let's go over to the ICOM and review its controls in the same fashion.

Starting with the front-panel layout, you see concentric controls for AF/RF GAIN, SQUELCH/TONE (yes, an actual tone control on receive audio!), and MIC GAIN/RF PWR. Directly above these are push-button switches for VOX, noise blanker, AGC time constant, METER (in FM it's a discriminator meter), PREAMP for the optional AG-1 mast-mounted preamp, and mode selective scan, which selects only those stored memories for the mode in use to be scanned.

Directly to the left of these controls are the mode switches (FM, USB, LSB, and CW) and the desired front-panel TRANSMIT switch. Above it are the offset write control, CHECK control (a repeater reverse switch), +Duplex and −Duplex switches, tone encoder control, and tone select (which selects the subaudible tones available on the built-in subaudible encoder).

To the right of the vfo are controls for tuning speed; dial function select, which chooses either vfo or memory-select operation; SPLIT to split vfo's; UP/DOWN for stepping through the band in 1-MHz steps; a continuously variable RIT that has an excursion range of 9.9 kHz either side of the center frequency. Finally, the upper right corner contains the A=B, A/B, WRITE, SCAN, VFO/M, and M>VFO switches, which function as their counterparts on the TS-811A do.

The display on the 471A contains a lot of information similar to the TS-811A display and is equally easy to read. It displays frequency in use, along with the mode selected, offsets, memories in use, tone switch on, and RIT engaged with frequency excursion displayed. The vfo selected is also displayed.

Looking at the rear panel, you find the antenna jack (type-N), CW key jack, dc power socket, external speaker jack, and the provision for an optional computer interface unit, as well as the cover plate for the optional IC-PS25 power supply which fits quite snugly inside the transceiver.

Now for the human engineering part: The IC-471A wins hands down when it comes to the sensible layout and engineering of its controls. Nothing is confusing, and the most needed and frequently used controls are the biggest and are very accessible. The two hams who accompanied me to our test lab site felt much the same way—that the Kenwood had way too many "bells and whistles" and was confusing to operate. I did like the detent tuning option on FM built into the TS-811A, however. It's quite easy to overshoot your intended station with the silky smooth dial on the IC-471A, which isn't needed when tuning in FM stations 15 kHz apart.

The fact that the IC-471A is a bit larger doesn't hurt either! Having more room to space out all of those controls makes selecting them less confusing. Call it what you will, I maintain that the IC-471A is simply more user-friendly.

The Kenwood does get good marks for the audio reinforcement of the mode selected via audible Morse code. This feature is good when changing to SSB from CW during a contest and making sure you've picked the right sideband. The vfo dial is very smooth and a little tighter than the IC-471A dial, which I prefer since it's similar to the vfo knob on my Kenwood TS-430S.

Performance

Now let's move on to performance evaluation. For the critical tests, I used a Hewlett-Packard 8640 rf signal generator and 8554 Spectrum Analyzer with a 141T i-f unit. The power source was an Astron RS35M at 13.8 volts dc. The output of each radio was fed through a 200-Watt, 30-dB, 50-Ohm attenuator and into the analyzer for transmitter spectral purity measurements.

As you can see from Photo B, the Kenwood is phenomenally clean! It exceeds the FCC requirement of spurious emissions, being more than 60 dB below the carrier. We couldn't find the second harmonic! The IC-471A, on the other hand, just barely made the FCC spec (see Photo C) and hovered right at the −60-dB mark as shown on the scope display. The third harmonic is not much more attenuated at −65 dB.

Both radios feature continuously variable power output. In the minimum position, the TS-811A had 1.8 Watts of rf across 50 Ohms. This swung smoothly up to a maximum of 28 Watts with the control at maximum. On the IC-471A, the minimum power was 6 Watts; with the control fully open, the power output was 30 Watts. Both radios met the claimed power specification of 25 Watts. These tests were made with a Bird Model 43 wattmeter, using a 10- and a 100-Watt slug into a Termaline coaxial resistor and short 9913 coaxial jumper.

Receivers

Now, on to the receivers. We first evaluated minimum discernible signal (MDS) on both receivers. For the TS-811A and the IC-471A, that number was the same at −140 dBm, or .023 uV. A reading of S1 took .26 uV of signal on the IC-471A, while a similar reading on the TS-811A required .5 uV. Neither radio met its claimed performance specifications for sensitivity (less than 0.30 uV for 10 dB S+N/N for the IC-471A and less than 0.14 uV for 10 dB S+N/N for the TS-811A), although the ICOM was a bit closer.

In FM mode, the MDS for the TS-811A was −130 dBm (.07 uV), while the IC-471A needed −123 dBm (.16 uV) to register. The TS-811A achieved full quieting signal (20 dB of quieting) with −103 dBm or 1.5 uV of signal, and it took the same amount to create 20 dB of quieting on the IC-471A. This figure was not as good as ICOM claimed, and the Kenwood didn't measure up either.

Selectivity and Sensitivity

As regards selectivity, both radios passed with flying colors and exceeded their claims. For the TS-811A, selectivity of more than 2.2 kHz @ −6 dB in SSB/CW and more than 12 kHz @ -6 dB in FM was in agreement with our measurements. Same thing for the IC-471A, with claims of more than 2.4 kHz @ −6 dB in SSB/CW and more than 15 kHz @ −6 dB in FM mode. These radios are selective, indeed.

Squelch sensitivity was next. For the TS-811A, the claim was less than 0.16 uV at the threshold level. We measured .2 uV in SSB/CW, and .09 uV in FM mode. On the IC-471A, the claim was less than 1.0 uV in SSB/CW mode and less than .3 uV in FM mode. We showed .23 uV to break the squelch in SSB/CW and .1 uV in FM mode. Incidentally, the S-meter readings varied wildly between units. It took .026 mV to register S9 on the IC-471A and .01 mV to make the grade on the TS-811A. Finally, we measured FM bandwidth to be about 9 kHz on the IC-471A with some noticeable distortion and 7 kHz on the TS-811A with noticeable distortion.

Summing up, both radios exaggerate their sensitivity claims, but are better than their claimed selectivity figures. Both units would definitely benefit from a well-designed preamplifier ahead of the front end. (The front end in the TS-811A is a 3SK129, while the IC-471A uses a 3SK48 MOSFET.) There's no reason why these units could not have been outfitted with a well-designed GaAsFET front end. Kenwood is already putting GaAsFETs in its 144-MHz FM rigs! The 3SK48 is a good MOSFET, but it really doesn't have the noise figure of a good microwave transistor or GaAsFET. The casual user might not notice the difference on FM, but it'd be very obvious in the SSB/CW mode. My advice? Buy a good external preamp.

Testing

Last but not least, I put the units on the air for comparison. The control station was my Kenwood TS-430S with a Microwave Module ahead of it, using a microwave transistor in the front end. I used a Bird Coaxial Switch to instantly switch the antennas—4 x 21 element F9FT beams—to the three radios.

Reports were surprising. Using identical microphones on the TS-430S and TS-811A, the stations I worked preferred the audio quality of the TS-811A better. But the IC-471A gathered the best reviews for audio with the standard HM-12 microphone from every station polled except one. I discovered that the speech processor made little or no difference on the TS-811A as compared to the TS-430S. The IC-

471A, of course, has no processor. Received audio sounded best to me on the TS-430S, with the TS-811A second and the IC-471A a distant third. The unit really does need the tone control, as the ICOM's audio is very bassy on receive.

I measured the starting frequency to be 432.100 for our tests, confirmed with the station on the other end using a counter. The display on the TS-811A read 432.100.1 and the IC-471A read 432.099.2. We noticed some drift on both radios, and after about one hour, my TS-430 system and the listening station's system were still on frequency to each other at 432.100, but the 471A had to be readjusted to 432.099.1 and the 811A to 432.100.3. Acceptable, considering the frequency.

I switched to CW and all three radios received nice reports for the waveform with no perceived key clicks. The TS-430 and IC-471A both offset nicely in the CW mode, giving the listening station an 800-Hz note. The TS-811A had no offset whatsoever and had to be tuned in to obtain the beat note, which is a pain in the neck. A steady signal to produce an S9 +10 signal here on the TS-430S registered about S7 on the TS-811A and S9 on the IC-471A, confirming our previous measurements. As stated earlier, the agc is adjustable on the IC-471A but not on the TS-811A, being selected with the mode in use, so I couldn't evaluate it fairly.

All told, the two multimodes performed about as I expected against the transverter/HF-radio combination. Both multimodes really need preamplifiers to make the grade on 70 cm. Both acquitted themselves well in a short period of FM repeater operation, receiving good audio reports. Note that the microphone gain on FM with the TS-811A is fixed and not controlled by the front-panel MIC control! Now, why the heck is that? It's adjustable in all modes on the IC-471A, which is a real plus. Another strange engineering design from Kenwood, perhaps?

The Final Evaluation

Overall, if I had to buy one or the other, I'd go with the ICOM IC-471A over the Kenwood TS-811A for two reasons: First, the front panel is very well laid out and the controls easy to use. Second, the receiver is a bit more sensitive than the TS-811A, and ICOM makes a companion mast-mounted preamp for the unit, which Kenwood either doesn't make or isn't importing at this time. The quality of the ICOM transmit audio also impressed me.

Although the Kenwood has some clever features and by far the cleanest transmitter, I wouldn't use most of the bells and whistles in day to day operation, and they are so closely integrated into the basic operation of the radio that they become somewhat confusing. I will say in its favor that the TS-811A has a nice feel on the vfo and the channelized detent tuning option is great to have on FM, as opposed to a smooth spinning dial.

Thanks to Joe Dolan KA2KWS for the use of his IC-471A and to Bill DiCarlo KA2QEP of QEP's Electronics for the use of his TS-811A.■

MFJ-1270 TAPR-2 Packet TNC

by Marc Stern N1BLH

MFJ Enterprises, Inc.
Box 494
Mississippi State
MS 39762
MFJ-1270—$129.95

At last, someone has made packet radio available to the common ham. MFJ Enterprises of State College, Mississippi, has introduced a TAPR TNC-2 clone that's every bit as good, if not better, than the original.

And, in what may come as a surprise to many who expected the MFJ unit to work well but be inexpensively made, the MFJ-1270 Packet Radio Terminal Node Controller (Photo A) is a very well made unit. MFJ has done it right.

Look at the printed circuit board (Photo B). It's a class act and definitely not a simple phenolic board. Instead, it is double silver-plated with plated-through holes. The motherboard looks as if it comes right from a computer room. All of the components are socketed, which is another plus because it allows you to keep up with the latest changes in software. All MFJ has to do, in this case, is burn new programmable read-only memory chips and send them out to customers who can then insert the new software.

As it is, the MFJ TAPR-2 clone has the latest revision of the TAPR-2 software. The date on my evaluation unit read 12/30/85, and I have to believe that this is the latest or one of the latest revisions of the TNC software.

A tiny unit, it is 7-3/8" wide by 1-1/2" high by 9-1/2" deep, and it weighs about two pounds. This puts it on a par with other low-powered, portable units on the market. In fact, the MFJ TNC is built to run off 13.8 V dc. That means it is perfect for portable low-power operation, such as in an emergency when you have to move and handle high-speed traffic in the field.

It's a far cry from the TNCs of a year or so ago that were anchored to 120 V ac and wall outlets. This definitely limited the effectiveness of the TNC.

Essentially, the MFJ board is a plug-and-play unit. Since it contains the latest TNC program, all you need is a computer and a terminal program in the computer. The TAPR board acts as if it were a remote system—which it is, really—and the computer communicates through its telecommunications program with the TNC. You don't need any special program to use the MFJ TNC because everything is built in.

Connecting the TNC and computer is easy because a standard serial interface has been implemented. This means that a straight-through RS-232C cable attached to a serial port will work quite nicely. MFJ also includes an eight-pin Kantronics-style connector and cable, as well as a five-pin DIN cable with which you connect your radio and the TNC.

A series of DIP switches on the rear (see Photo C) sets the speed of the TNC's serial port. I left the evaluation unit set for 1200-baud, a 7-bit word length, and 1 stop bit. I then reconfigured my computer's communications software to conform, which was the easy way of doing things from my point of view.

You needn't do it that way, of course, because the TNC is actually a tiny computer in its own right. And since it is a computer, it's programmable. That programming is handled via the built-in terminal software used by the TNC to communicate with the computer. You hit the CTRL-C combination (on an IBM PC, anyway) which puts you into command mode where you can set just about any parameter you care to think of—including word length, parity, and the like.

This programming also sets up the TNC for use at your station. Your station's call is used as the TNC's identifier to the packet network. It recognizes the standard AX.25 network protocol and, like any TNC, will also act as a digipeater, as well as a beacon. This feature is

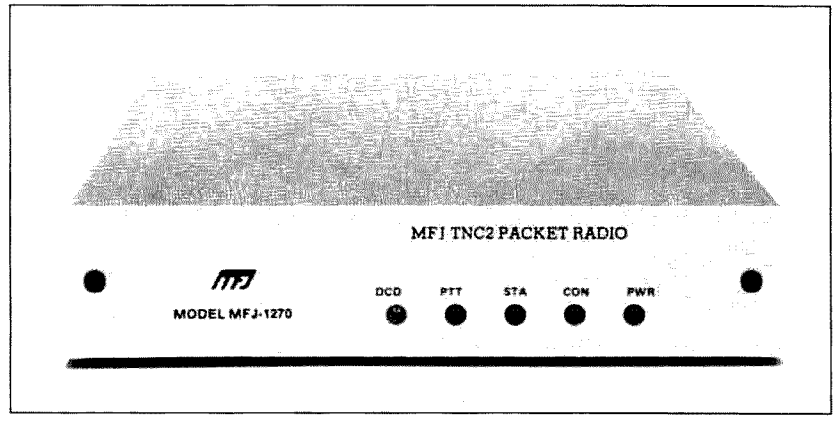

Photo A. The MFJ-1270 TNC-2.

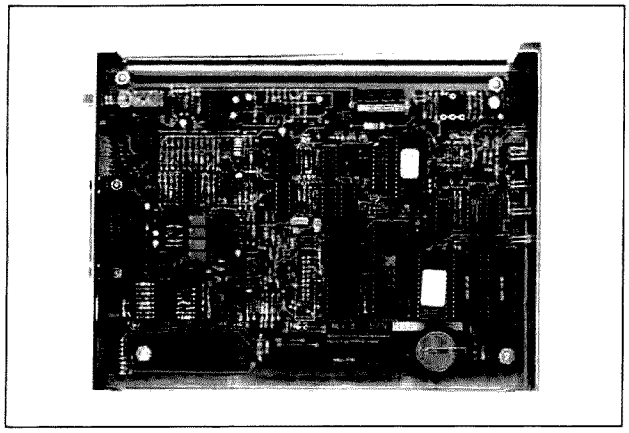

Photo B. The printed circuit board.

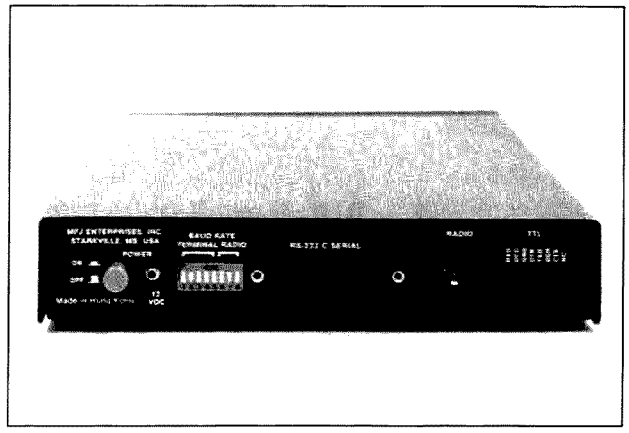

Photo C. A rear view of the MFJ-1270.

user-selectable, as is the TNC's ability to recognize both V 1.0 and V 2.0 of AX.25. Just about every feature of this TNC is user-selectable.

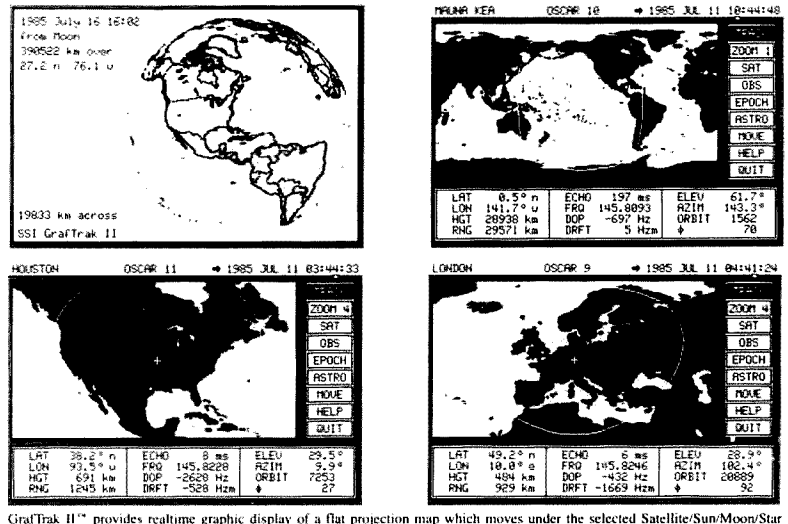
The CPU of the MFJ-1270 TNC-2 is a Z-80. It is backed by 16K of RAM and 32K of ROM. The ROM holds the monitor routine for the TNC, as well as the firmware program. The RAM is the user scratchpad.

There are so many features to the TNC-2 that I'll just have to touch on the highlights. In action, the MFJ-1270 TNC-2 is ready to go right from the box. It's simply a matter of wiring up a microphone connector for your VHF FM rig and putting it on the air. MFJ notes correctly in its manual that using the TNC in this manner is inconvenient if you use the rig for FM phone work, too. It offers an interface box which allows you both packet and phone options. It looks like a good idea. Not only does MFJ offer such a unit, it also gives you the schematic so you can build your own. It's a nice touch.

I found that the 1270 was set up to work correctly from power-up. To MFJ's credit, though, the manual does tell how to remedy problems if the tones aren't set up correctly.

The switching time of my evaluation 1270 matched the Kenwood TR-7930 with which it was primarily used. Both the radio and the TNC handled my input with no problems. I used shielded cables for all the cabling; this also helped ensure reliability because it kept noise interference to a minimum—which can be a problem when you're dealing with cabling several pieces of computer equipment together. I suspect ribbon cable would create noise problems and would urge anyone considering packet to use shielded cabling.

I did run into one problem, though, when it came to cabling, and that was due to pilot error. As most hams do, I usually attempt to do something before reading the documentation thoroughly. Most of us will read enough to find the on-off switch and then start playing.



I did this with the 1270 when it came to cabling up the microphone connector, then followed the diagram rather than reading the text closely. After I had finished wiring the cable, I found it didn't work. When I read the documentation, I found that it noted that cables would vary from the diagram and that each buyer would have to check out the connections with a volt ohmmeter for continuity. The only correction I would urge is keeping all the cabling the same or just providing a DIN connector and a picture of the 1270's requirements. Leave the color-coding off the diagram because many people will follow it rather than read the documentation.

The manual is the best I've ever seen from MFJ. Over 200 pages long, it is readable and covers every aspect of the TNC from interfacing (with a comprehensive discussion of serial interfacing for major computers through setup—and a two-part tutorial) to a detailed discussion of the command set and error messages, as well as a technical discussion of the TNC. It also covers—as do all of MFJ's manuals—the TNC's theory of operation and provides a comprehensive set of schematics.

MFJ has done it and I still wonder how. The Mississippi ham radio manufacturing firm has brought in a sub-$130 TNC that's worth much more. It deserves a look by anyone serious about packet. Reader Service number 152.■

GET A BIRD'S EYE VIEW

From GrafTrak II™ and your IBM® PC

GrafTrak II™ provides realtime graphic display of a flat projection map which moves under the selected Satellite/Sun/Moon/Star coverage circle and updates once per second. Spherical projection views and graphic screen dumps to an IBM/Epson/Oki printer can also be produced. Requires an IBM PC, PC/XT, PC/AT, or true compatible, an IBM Color/Graphics Monitor Adapter or true compatible, 8087 math coprocessor, minimum 256K RAM with 512K recommended, DOS 2.0 or later, and either two 360K floppy drives or one 360K floppy and one hard drive.

SILICON EPHEMERIS™ provides tabular data output to the screen, printer, or disk file for the following operating modes: 1 observer to 16 satellites, 16 observers to 1 satellite, schedule for 1 observer to 1 satellite, window between 2 observers and 1 satellite, rise and set times for 1 satellite, time ordered rise and set times for 16 satellites, Almanac for Sun and Moon, 16 observers to Sun/Moon, schedule for 1 observer to Moon, window between 2 observers and Moon, schedule for 1 observer to Sun. Requires either an IBM PC, PC/XT, PC/AT, or true compatible, and IBM Monochrome or IBM Color/Graphics Monitor Adapter or ture compatible, an optional 8087 math coprocessor, 256K RAM, DOS 2.0 or later, and one 360K floppy drive.

Each package includes SED, an editor program to construct and modify Satellite/Observer database files. These products can be run from a hard disk and are not copy protected.

GrafTrak II™ and SILICON EPHEMERIS™ are priced at $119.95 each or $199.95 for both. Texas residents add sales tax. Order by check, money order, MasterCard, or VISA.

A Walk Through the VHF/UHF Spectrum

KT2B surveys ham radio's biggest allocation—the bands and modes above 50 MHz.

In this article, I'll try to provide a brief but concise overview of the amateur spectrum space above 50 MHz. In doing so, I'll try to answer questions such as: (1) How many frequencies do we have up there? (2) Who's using them? (3) How can I (the reader) better use them? (4) Who makes equipment for those bands anyway? (5) You mean I can actually work England and South America on 6 meters?

Actually, we in the amateur service are quite fortunate with our spectrum allocations. Table 1 shows the most active bands. The only group with access to more spectrum space is the U.S. government itself! Yet, much of this spectrum space lies largely dormant, either due to ignorance or just laziness. As time marches on and pressure mounts from groups outside the amateur radio service, we'll be hard pressed to justify retaining these privileges unless we make better use of them, for as you well know "possession is nine-tenths of the law!"

The 6-Meter Band

For starters, consider the lowest frequency allocation: 6 meters. This band occupies the frequencies from 50–54 MHz and is a rather unusual animal. For example, although it is truly a VHF band based on spectrum position, it often behaves like an HF band owing to different types of propagation that may occur. The most common is sporadic-E, *Es* for short. This condition is prompted by sunspot activity and results in sporadic ionization of the E layer of the ionosphere. (Typical HF propagation occurs in the F layer of the ionosphere.) When this happens, contacts may be made with stations located thousands of miles away, often with low power levels. Severe thunderstorm cells frequently accompany this phenomenon, which has been extensively researched over the years.

A type of propagation that occurs less frequently nowadays on this band is F2 layer propagation, similar to that which occurs on the lower frequencies. Right now, the sunspot cycle has bottomed out but is climbing up again; so in about five years, F2 propagation will be at its peak on this band. Here the possibilities are greater for DX: It's quite common to work into Japan from the West Coast or into England and Africa from the East Coast. One fine example of what F2 can provide is a contact made by Mike Crawford WA2VUN from his home in N.J. to a ZL in New Zealand, running 80 Watts to a single seven-element yagi.

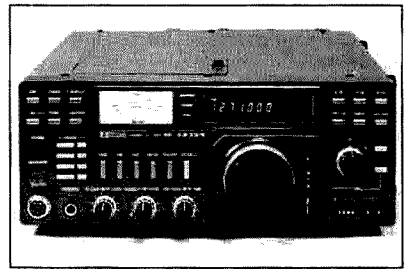

Photo A. ICOM's IC-1271A 1.2-GHz transceiver.

Many 6-meter fans have WAC certificates, largely due to F2 propagation. Now that amateurs in Great Britain have received 6-meter privileges (although somewhat limited), it will be possible to make the W2-G2 contact path more readily when the sunspot cycle peaks out. Many stations have already worked the British Isles via Es, which occurred several times last summer, forming paths from the Atlantic Coast states 3,000 miles across the sea to England. With the eventual abandonment of TV channel 1 in Europe in favor of UHF color channels, most of the continent should receive the 50-MHz allocation in time for the next sunspot peak, providing new DX enjoyment for 6-meter types.

Aside from these modes, another popular form of DX and one that takes a considerable amount of skill is Meteor Scatter, which involves the use of ionized meteor trails to reflect 50-MHz signals over several-hundred-mile paths. It takes a lot of patience and repetition to make a scatter contact since most of these meteor "bursts" or "pings" are very short in duration and occur during the early morning hours or during intense meteor showers.

Normal 6-meter propagation is on the order of a few hundred miles at best. You can detect enhanced propagation by watching TV channel 2, 3, or 4 for distorted, breaking-up video with heterodyne beats as another distant signal is received. Often during Es, the distant signal will replace the local station completely for a few minutes, and you'll have the rare pleasure of watching a Miami weather report on your screen in Cleveland! (Neighbors who know you're a ham will blame *you* for this condition by attributing it to TVI!)

For the average station, 50 to 100 Watts and a single five-to-seven-element yagi will do the trick for SSB/CW work. The higher your antenna, the better. (This also helps to reduce possible TVI, as the increased vertical spacing between your 6-meter antenna and the nearby TV yagi also increases the attentuation of out-of-band overload products.) Most transceivers made for 50 MHz could stand the help of a good, well-designed MOSFET preamplifier with 12–16 dB of gain. Some of the transceivers available (like the ICOM 551/551D series) make provision for such a preamp.

Don't let TVI scare you away from the band, either. In many areas, the penetration of cable service has all but eliminated this problem (assuming the system operator runs a clean shop!). Most often TVI is caused by using high-gain yagis and placing them at the

same height as most of the neighboring TV antennas, which is just asking for trouble. Get it up in the air as high as you can! Of course, there's no reason why you can't go 6-meter mobile or portable with horizontally polarized antennas as well, and take advantage of the nearby hills to chase DX on 50 MHz.

Another mode of operation that has achieved some popularity on the band is FM operation. Although there aren't many, 6-meter repeaters are distributed throughout the United States and can be accessed with a few Watts from a portable or mobile rig. When Es is present, you can have quite a time with FM, working through repeaters hundreds of miles away! Unfortunately, there aren't too many FM mobile rigs being made these days by the major manufacturers, so you'll have to dig around to see what you can come up with used. The 50-MHz band is a valid allocation in Japan; so, when the sunspot cycle was at its peak, we were flooded with all sorts of 6-meter radios—portables, mobiles, and multimode base stations. They're still around at flea markets for a good price.

Right now, the choices for new 50-MHz radios are somewhat limited to the ICOM 551D, ICOM 505, and Yaesu FT-726R with 6-meter module installed. You can also go the transverter route with Microwave Modules' MMT-50-28 or 50-144 units, the new Mutek TVVF-50 transverter, or kits from SSB Electronics and Hamtronics. Used radios that fit the bill include the Kenwood TS-600, Drake TR-6, Heath SB-110, Yaesu 627RA, and ICOM 560 mobile radios. Portable choices include the ICOM 502 and the Yaesu FT-690. Kenwood and Yaesu also make transverters to match their HF radios, which you can often purchase very reasonably. Antenna manufacturers include KLM, Hy-Gain, and Cushcraft. Sources for amplifiers are somewhat limited. Mirage is the only U.S. manufacturer making a 100-Watt solid-state unit at this time—perhaps more will come on the market as the sunspot cycle approaches its next peak.

6 METERS	
50.000–50.100	CW, Beacons
50.100–50.500	CW, SSB, AM
50.110	Calling Frequency
51.000–51.100 and 52.000–52.100	Pacific Calling Frequency
50.500–54.000	FM and Repeaters

1295.000 MHz–1297.000 MHz	CW, SSB
1296.090 MHz	Calling Frequency
1297.000 MHz–1300.000 MHz	Mixed Use

Table 1. Modes used on the most active VHF/UHF bands.

The 2-Meter Band

Moving up the dial, switch your attention to the 144-MHz or 2-meter band, as it is more commonly called. This is the most densely populated amateur allocation in the entire world, largely due to the phenomenal popularity of FM and repeater operation. It's also the band on which the OSCAR Mode B downlink frequencies are located. In North America, South America, and Japan, the 2-meter allocation runs from 144–148 MHz, while in Europe it's limited to 144–145 MHz.

Normal propagation is considered to be line of sight on this band, and with gain antennas and some power, the average distance worked is in the range of about 50–100 miles. Most of the activity on 2 meters consists of FM repeater operation, with SSB/CW operators usually found down around 144.100–144.200 MHz. Packet operators have carved out frequencies near 145.000 MHz for their simplex operations. Moonbounce types frequent the area below 144.050, and the OSCAR downlinks are in the range near 145.800 MHz. More equipment is sold for this amateur band than for any other in the world, as well!

Enhanced propagation on 144 MHz comes in many forms: First and most commonly encountered is tropospheric propagation, or tropo for shorthand. This phenomenon occurs when temperature inversions are present—that is, for a given increase in altitude, the air temperature actually increases instead of decreases. When this happens, layers of warm air are often sandwiched between layers of cold air and a duct is formed along the boundaries, carrying signals along much like a waveguide. Users of repeaters are very familiar with this condition in the late summer and early fall, usually in the morning hours.

Strong storm systems in the area can induce tropo, with the intensity of the ducting effect proportional to the areas of the cold and warm air masses as they overlap. Tropo ducts also form at higher altitudes, and stations below the duct are often unaware of activity inside the duct. In this country, most tropo occurs along the coastal regions—mainly the Atlantic Coast and the Gulf of Mexico, and the Pacific Coast to a lesser degree. The path from Hawaii to Southern California has been worked many times on 144 MHz via tropo.

A form of propagation that can show up at any time on 2 meters (and on 6 meters, as well) is aurora, which is related to sunspot activity. During auroral propagation, signals are reflected off the auroral curtain and received 800–1,000 miles away, depending on the intensity of the aurora. This type of propagation occurs more frequently at higher

latitudes, with stations in the Northeast, Upper Midwest, and Canada able to take best advantage of it most of the time. When aurora is very intense, stations from the southern United States will often be heard off the curtain.

Still another form of enhancement is Es, which occurs much the same way as it does on 50 MHz, but far less often. Usually strong storm cells over the Midwest and Southwest provide the best conditions for long-haul DX, observed mainly during the months of June and July. You can often detect sporadic-E by listening to FM broadcast stations or watching TV channels 7–13 for interfering stations outside the normal coverage area. The higher the channel it's observed on, the more intense the Es. A rule of thumb is to watch the Es on 6 meters, and when it becomes quite short—200 to 300 miles—move to 2!

Just as on 6 meters, you can work meteor scatter with patience and determination. It's more fruitful to pick a major shower to do it, though, as the pings from everyday meteorite trails are harder to detect than on 10 and 6 meters. Good, high-gain antennas and schedules are a must, as well as a fair amount of power to make it worthwhile. And as I mentioned earlier, moonbounce operation, or EME (Earth-Moon-Earth), is very popular on 2 meters. Stations here usually run large four-bay or larger antenna arrays with legal limit amplifiers to overcome the 200+ dB path loss from here to the moon. Low-noise GaAsFET preamplifiers find favor in this application.

There is a bewildering array of equipment for 2 meters currently available! At least eight Japanese and one U.S. manufacturer have FM handie-talkies available for the band, not to mention mobile FM radios. In addition, there is a preponderance of 2-meter multimode radios for both base station and car, as well as the world's only multimode handie-talkie (Santec LS-202). Three companies in Europe have gone the other route and manufacture transverters for the band, so as to employ HF multimode transceivers as i-f frequency TX/RX sources, most often in the 10-meter band. Examples of these would include the popular Microwave Modules' MMT series, as well as Mutek and SSB Electronics.

There's a plethora of antennas to choose from as well—KLM, Cushcraft, Jaybeam, CueDee, Hy-gain, and Tonna to name a few. Most users of FM employ vertically polarized antennas, such as ground planes and J-poles, while SSB/CW users employ horizontally polarized yagis, with as many as 19 or 20 elements. This is often the reason why newcomers to weak-signal work can't hear any activity, as they are still using their vertical arrays!

There are many manufacturers of amplifiers for 144 MHz as well, with Mirage, TET, Alinco, THP, and Microwave Modules being among the more popular solid-state models. Henry Radio manufactures several versions of a 2-meter amplifier using 3CX800 and 8877 tubes, which find use largely with the moonbounce set and weak-signal enthusiasts.

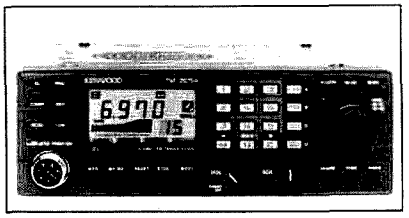

Photo B. The Kenwood TM-2570A 2m mobile radio.

As far as the OSCAR users are concerned, multimode transceivers for 432 MHz and 144 MHz or transverters are the order of the day, with "twist" polarization (antennas using both horizontal and vertical elements) yagis and 100-Watt amplifiers.

Two meters is a perfect example of what happens when amateurs take to a certain band and populate it: The amount of equipment available goes up in direct proportion! It's probably the most secure allocation we have above the HF bands, directly due to the activity. Unfortunately, the same cannot be said for the next band, 220 MHz, which has long been the stepchild of our VHF allocations. In fact, you can consider 220 MHz to be a UHF allocation in the scheme of things, lying above TV channel 13 at 220–225 MHz.

The 1-1/4-Meter Band

The 1-1/4-meter band is a rather unique allocation; in all the world, only we in North America can use it! This certainly explains the lack of commercially made equipment for the band, with nothing being manufactured here in the United States and the only transceivers coming in from Japan—where the allocation doesn't exist. At present, only ICOM makes a mobile FM transceiver for the market. Kenwood, ICOM, and Yaesu make hand-helds for 220, as well. In addition, for some time Hans Peters VE3CRU of Transverters Unlimited has been making modified 220 Microwave Modules that work with HF multimode radios. SSB Electronics is also introducing equipment for this market.

What can you work on 220? For one thing, the propagation under normal conditions closely resembles 144 MHz, with line-of-sight conditions being the rule on low power. With a gain antenna and some power, 50–100 miles is possible. Enhanced propagation takes several forms, with the most common being tropospheric propagation as on 2 meters. This occurs mostly from late summer through fall and can result in contacts in excess of 500 miles, mostly along coastal areas.

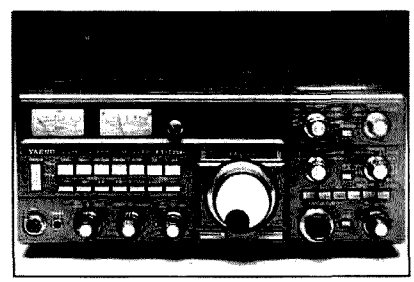

Photo C. Yaesu's FT-726R multimode, multiband transceiver.

During periods of sunspot activity, 220 contacts can be made via aurora, again in the same manner as 2 meters, with stations in the northern regions of the United States having the best propagation. Meteor Scatter is also quite popular on 220 during strong showers, such as the Perseids in early August. Again, schedules are a must here; otherwise, you'd never hear the minute-to-minute "pings" from random meteorites entering the atmosphere. As far as Es is concerned, there haven't been any strong documentable cases for it lately, though this will likely change when the sunspot cycle peaks out in about five years.

Operation on 220 mainly consists of FM and repeaters. In fact, many users of 220 have tired of the crowded conditions on 2 meters and have moved up to what they consider to be a more "civilized" band, especially in urban areas. In those areas, most of the coordinated repeater pairs have long been assigned, yet many of the machines are "dormant" much of the time. Down at the far end, you'll find the weak signal chasers and moonbouncers, with the former around 220.110 and the latter around 220.050. Moonbouncers in particular like this band since it is relatively "quiet" as opposed to its lower frequency brother. And with the band falling above TV channel 13, TVI is rarely, if ever, a problem, even with high power levels.

These advantages haven't been lost on other potential users of the band, so 220 continues under siege from a variety of special interests, who've come up with all sorts of "shared spectrum" proposals, as well as schemes to take the band away from hams outright and parcel it out to commercial users. The big problem is activity—there just isn't enough to ensure the long-term use of the band. So the big manufacturers in Japan are loath to come out with lines of full-featured multimode radios for 220, not trusting in its staying power. It's up to us to determine the fate of 220, and the old saw "use it or lose it" certainly applies here.

One group that appreciates the "quiet" on 220, as well as the abundance of repeaters, is the packeteers, who are multiplying on this band. Without the bother of continuous voice transmissions to contend with, the packet mode is a very viable alternative. Of course, the Novice Enhancement Docket before the FCC may change all of that, giving voice privileges on 28 MHz, 220 MHz, and 1260 MHz. It would result in more Novices on the band and in the long run may be what it takes to keep 220 in the amateur table of allocations.

As I said before, the equipment situation is somewhat tight. In addition to the 220 Microwave Modules, SSB Electronics will soon import a 220 transverter to the United States. As far as amplifiers go, Mirage and Tokyo HighPower make 220 units for 50–120-Watt

Photo D. Microwave Modules' MMT 144/28 R 2m multimode transverter.

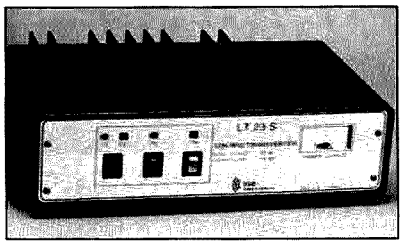

Photo E. The LT 23 S 1296-MHz transverter from SSB Electronics.

output, using HTs or mobile rigs as exciters. In the higher power range, Henry Radio makes a version of the popular 2004 for this band, using the 3CX800. Antennas are available from both Cushcraft and KLM, as well as mobile whips from Larsen. A good deal of the operators on 220 have rolled their own equipment, for obvious reasons.

The 70-Cm Band

Now, let's take a big step up to our next allocation: the 70-cm band, or 430–450 MHz. Originally, this band included the range 420–430, but recent FCC restructuring has removed the lower 10 MHz from amateur use. Here's a band that's larger than 6, 2, and 1-1/4 meters *combined*. It's also a worldwide allocation, so equipment is plentiful and not that expensive. Whatever your fancy—from weak-signal work to ATV, OSCAR, FM, and repeaters—there's plenty of room to engage in it on 70 cm.

Here is a true UHF band. Signals travel line of sight and can be affected by objects of varying density in the signal path, such as trees, buildings, and even clouds of moist air. Yet, since the 70-cm band is largely unaffected by sunspot activity (and subsequently any sporadic-E), it's a preferred choice for such services as commercial television in Europe. Since the wavelength is so small, high-gain multiple-element yagi antennas are possible using only 15 feet or so of boom length.

Propagation enhancement usually occurs via tropo. In some cases, it's so intense that astounding distances can be covered. For example, during the hurricane last September that hit along the East Coast of the United States, signals from Florida were heard into Connecticut and Massachusetts! Tropo ducting is quite common at this frequency, although you usually have to be up a bit in elevation to hook into the duct. Signals can also be worked via aurora on rare occasion, as happened this past February when intense sunspot activity resulted in auroral activity from 50 MHz through 432 MHz! Stations were heard working grid squares from the East Coast into Illinois, Ohio, Michigan, and Indiana via the "buzz."

Starting at the low end of the band around 432.010–432.050, you'll find the moonbouncers. This is a very popular band for EME since you can construct high-gain arrays that don't take up much room. Many European and Japanese EME enthusiasts go mobile or portable for their contacts, towing their arrays along on trailers. Power becomes somewhat more difficult to generate on 70 cm as many of the popular ceramic power tubes don't carry full ratings through 400 MHz. However, the problem of Faraday rotation, the slow shift of polarization on reflected signals from the moon, is less pronounced on this band. It takes longer for the wave to shift—often minutes—as opposed to 2 meters, where the shift occurs at a rapid rate.

Next, you find the weak-signal types around 432.110 MHz, the national calling frequency. SSB and CW work is plentiful on 70 cm, especially during contests. Many operators use multimode transceivers to cover these modes, and, of course, there are many transverters made for the band.

Going further up, you run into the OSCAR uplink frequencies in the range 435–437 MHz. These are the inputs for Mode B with corresponding outputs on 2 meters. The ATV crowd is next, for the 70-cm band is the lowest frequency allocation that permits Fast Scan Amateur Television. Many stations are on in color, and there are ATV repeaters located on tall buildings in urban areas.

Finally, you run into the FM crowd above 440 MHz. Like 220, the 440 allocations are largely used up in the major urban areas, but many of these repeaters are closed repeaters, using PL or tones to unlock the machine for use by members. The national simplex calling frequency on FM is 446.000.

As you might expect, there's no shortage of equipment to choose from on 70 cm. All of the major Japanese manufacturers make both hand-helds and multimodes for base and mobile operation. The major European manufacturers offer transverters for the band, as well as ATV transmitting and receiving converters. Since many of the radios on the market usually suffer from less-than-acceptable front-end sensitivity, there's an abundance of preamplifiers available for both station-mount and mast-mount application. Serious users of the band employ low-loss cables such as 9913 and hardline for transmission lines, since the average coax used at HF is too "lossy" here. Also standard in most cases is the use of low-loss 50-Ohm connectors, such as type N and BNC.

Amplifiers are also plentiful. Alinco, Mirage, TET, Microwave Modules, and Lunar make solid-state versions with outputs up to 140 Watts. For the higher power requirements, Henry makes the 2004 and 3004 using 3CX800 and 8877 tubes. Antennas are available through a variety of sources, including KLM, Cushcraft, Hy-gain, Larsen, CueDee, Tonna, and Jaybeam. OSCAR operators will employ the "twist" type of antenna for the uplink mode, while ATV operators will go for horizontally polarized yagis, along with the moonbouncers and weak-signal operators. All FM operation uses vertical polarization.

OSCAR Mode L, used less frequently than Mode B, employs uplinks on 1269 MHz and downlinks on 436 MHz. At this time, packet operation on 70 cm is sketchy at best. But due to the combination of spectrum space, worldwide popularity, and availability of equipment, 70 cm could easily become the next most popular band after 2 meters! Already in Japan, reports are made of the type of congestion we experience here on 144 MHz, with FM being again the predominant mode.

The 23-Cm Band and Above

Before closing, I'll touch briefly on the SHF bands, namely 23 cm and above. The 1260-to-1300-MHz band is coming on fast, especially in Europe and Japan. Here's a band that's twice as big as 70 cm! Again, the popular modes are SSB/CW, ATV, OSCAR, and FM. Propagation is essentially limited to tropo. I've never heard of any auroral contacts via 23 cm, although during the February conditions, there were those who certainly waited patiently to be the first!

Moonbouncers also like 23 cm since Faraday rotation is even slower here and they can construct high-gain arrays or dishes in a relatively small square area. Of course, power is more difficult to generate here, so most of the amplifiers you'll hear are home-brew, generally employing triodes such as the 7289/3CX100. Even 9913 exhibits high losses at this frequency, so hardline is the transmission medium of choice.

Equipment available includes the new ICOM IC-1271A 10-Watt multimode base for SSB, CW, FM, and ATV. ICOM also makes the IC-120 mobile FM radio with 1 Watt of output. Kenwood makes the TR-50 FM portable, also running 1 Watt from a self-contained battery-operated unit. High performance transverters are readily available from Microwave Modules and SSB Electronics, makers of the popular LT-23S 10-Watt transverter. GaAsFET preamplifiers abound at this frequency, since they are a necessary evil for serious weak-signal work.

Antennas are made by Tonna of France and Jaybeam. DownEast Microwave manufactures a fine line of loop yagis for 23 and 13 cm. Larsen makes a 23-cm mobile antenna, based on a cellular design for 800 MHz.

Most often, the inhabitants of this band like to roll their own antennas, but it's a tricky task as mast supports often exceed the length of the driven and parasitic elements! Hence, most users place the beams at the very top of their masts or make up side arms with vertical supports. Frequently, users of the band will experience reflection from such objects as airplanes and large buildings! Often refraction can occur over mountainous areas, and it's not unusual to hear lots of multipath on the signals when living in such an area.

At 13 cm, much the same conditions prevail, except very little is available for the band commercially except from Europe and a few specialty houses in this country. Loop yagis are very popular at this frequency, as are dish antennas. Transverters are available from such manufacturers as SSB Electronics of Germany, which sells a unit for 13 cm with an i-f at 144 MHz, running 3-Watt output. EME Electronics of Germany makes beautiful cavity amplifiers for both 23 and 13 cm, using two 7289 tubes to achieve 50-to-100-Watt output.

Amateurs have additional allocations at 10 GHz, 24 GHz, 48 GHz, and above, although it's hard to say who's active here other than the diehard experimenter and occasional contest stations. In addition, I've sidestepped the 902-MHz band, simply because it's such a new allocation that I'm not very familiar with it. I can tell you that there is activity on 902, as a repeater group was on the band the day it became available (from Texas—it figures!). SSB Electronics has indicated the availability soon of a 902-MHz transverter, as has Hans Peters of Transverters Unlimited. Many hams are modifying cellular equipment to cover this band with excellent results, seeing propagation similar to 23 cm.

Closing Remarks

That about covers our walk through the VHF/UHF spectrum, and as you can see there's plenty of room for expansion and experimentation. Indeed, these frequencies are the key to the future of the hobby, as we continue to try new modes that require greater bandwidths than our already-crowded HF bands can provide. If you haven't given one of these bands a try lately, why not pick up a transverter or HT and have a go! Many activities exist for the VHF/UHF operator, with no less than six national contests and many certificates to be had, such as the popular VUCC (VHF/UHF Century Club). It needn't take a lot of money, or a lot of space either. Set your sights high, for a change! ■

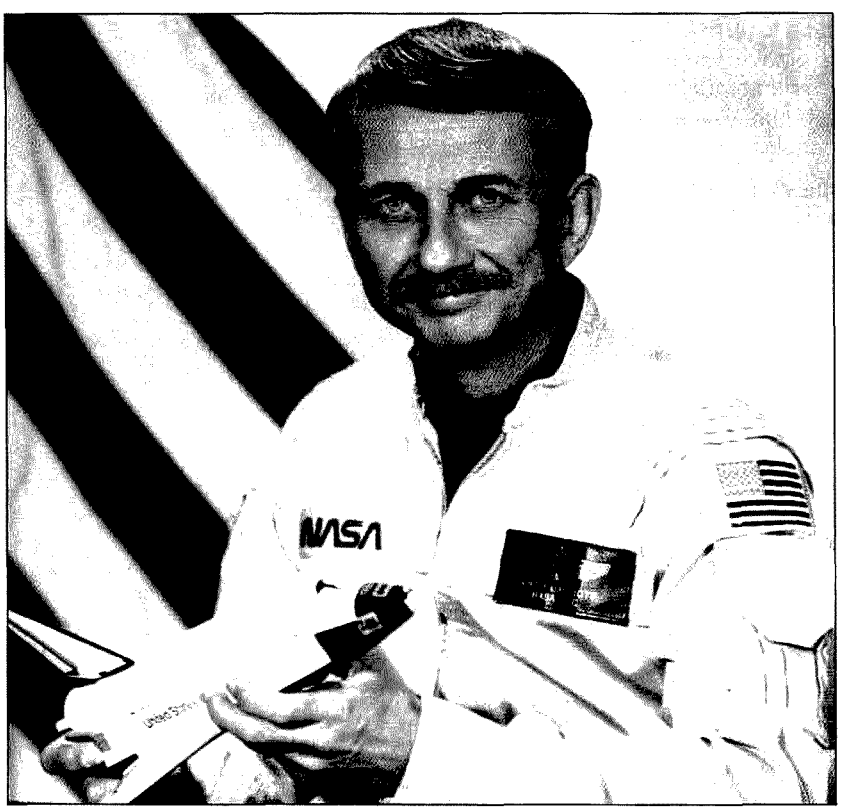
Hams in Space



An interview with Owen Garriott W5LFL and Tony England W0ORE.

The theme for this month's issue is "Above the Crowd—VHF and UHF Operation." Well, two guys who have certainly been above the crowd are NASA astronauts Owen Garriott W5LFL and Tony England W0ORE. Owen and Tony both have carried amateur radio into orbit aboard the space shuttle; we asked them to reflect a bit on their experiences, and on the past, present, and future of ham radio.—KW1O.

Owen Garriott W5LFL

KW1O: Owen, how long have you been a ham?

W5LFL: A looong time! I was still in junior high school when my father came home and said, "Son, a friend at the office is going to be giving code classes—would you like to go down and learn the International Morse code with me?" So we started; I was in 9th grade.

Owen Garriott W5LFL.

Then a little while later it was, "How would you like to go to theory classes?" We ended up getting our tickets together...that was during the latter part of World War II.

KW1O: Was there a club at school?

W5LFL: No, not at school. As far as I know there was no one else at school who was interested in this sort of thing. I took my classes at the local club in Enid, Oklahoma.

KW1O: Did your interest in radio lead you to a career as an astronaut?

W5LFL: Yes, I think that ham radio took me into electrical engineering and radio propagation—the heart of amateur radio. After graduating from the University of Oklahoma I had a three-year Navy obligation, and then went back to graduate school at Stanford and ended up in the radio propagation laboratory. After that I stayed on the faculty doing space research based on radio propagation, sending satellite transmissions through the ionosphere. Then NASA said they wanted people with my sort of skills involved in the manned space program. There's a pretty clear line of interest going from that code class to my present job.

KW1O: How much trouble was there talking NASA into letting ham radio aboard the shuttle?

W5LFL: Well, it wasn't an easy job. It isn't so much convincing people that it's a good idea as convincing them that there's nothing wrong with the idea. There are so many people who can say no, and that's so much easier for them to do. It's simple to get someone to say, "Yeah, that's a great idea, I hope it works." It's a much tougher job to convince people that this great idea of yours is not going to cost more, or interfere with the schedule, or reduce the time that their experiment might get, or set a precedent, or any number of objections that can be raised. And all along they're saying, "That's a great idea, I hope it works." There were at least a half dozen wickets to get through before the project left the ground. It's also very important

to have people supporting your project that are well-respected in the system—General Abrams, who was at that time head of the Office of Manned Space Flight, and Roy Neal K6DUE come to mind.

KW1O: You used a special Motorola-built hand-held with a window-mount antenna. Did Tony [W0ORE] take the same rig up?

W5LFL: It was either physically the same unit, or one functionally identical.

KW1O: How did it work?

W5LFL: We had a little antenna that attached to one of the windows. Of course, the rig had been pretty extensively ground-checked for interference and so on. Overall, it functioned very well.

KW1O: Would you do anything different if you took ham radio back into space?

W5LFL: Well, you always try to build on what you've done before. I think that for the first effort on Spacelab 1 we did just about the right thing. There are a few details that I might have changed, like letting people know not to transmit on the downlink frequency, but I think it went off pretty well.

KW1O: You worked a heck of a lot of people.

W5LFL: Yes, over 300. For the second effort, Tony went beyond that and took up SSTV. For the next time we should try something like packet, or a fast-scan TV uplink with a slow-scan TV downlink. Part of the trouble Tony had was that he couldn't hold a signal long enough to get a full frame of SSTV. It would have been OK if only one person had transmitted at a time, but that's not a very satisfactory way to operate. With a fast-scan uplink you only need to hold the signal for less than a second.

KW1O: What are you involved with at NASA?

W5LFL: I'm working on the space station project, making sure that the station design is an appropriate one for the various kinds of activities we'd like to do on it.

KW1O: Will there be a ham shack on the space station?

W5LFL: I would be very surprised if there was not. However, it is premature to start pushing in that direction. I think we'll get it on the basis of providing off-duty activities for the crew. There's a very good chance we'll have one for that purpose. We won't know for certain for three or four years—the station is scheduled for launch in 1992.

KW1O: Sounds like you have your hands full. Is there much time for on-the-air activity?

W5LFL: No, not really. I get on the local [Houston] repeater now and then, but that's about it.

KW1O: Well, Owen, thanks for chatting. And good luck with the space shack!

W5LFL: Thanks, it's been fun.

Tony England W0ORE

KW1O: Tony, you've been a ham for quite a number of years. What got you started?

W0ORE: Well, I started when I was about twelve. A buddy of mine and I built a couple of "secret transmitters" that we took to school. We got the plans out of one of the ham magazines. They were small CW transmitters, and the speaker was actually a vibrator that you could put against your arm.

KW1O: You must have done pretty well in class!

W0ORE: It certainly kept our interest up! But ham radio for me has been a series of peaks and valleys; when my professional life is particularly busy, hamming slides a bit. And when there's a lull in my professional life, I pick it right back up. My wife Kathi has always appreciated my hobby—it tends to keep me home.

KW1O: Is Kathi a ham?

W0ORE: No, she's not. I've tried, but I can't talk her into it. Actually, Kathi bought my last rig for me. When I was at school working on my doctorate, she thought it would help me keep from climbing the walls. Kathi thought talking on the radio was a lot of fun, but she just wasn't interested in getting a license.

KW1O: I wonder if some sort of Novice voice privilege would appeal to people like that?

W0ORE: I haven't been following all of the various proposals, but I can say that I'm very much in favor of some sort of digital class of amateur license. There are a lot of people who could really benefit from being amateurs, and who would bring their special skills to the hobby. Of course, there will always be people around who feel that the old way is the best way.

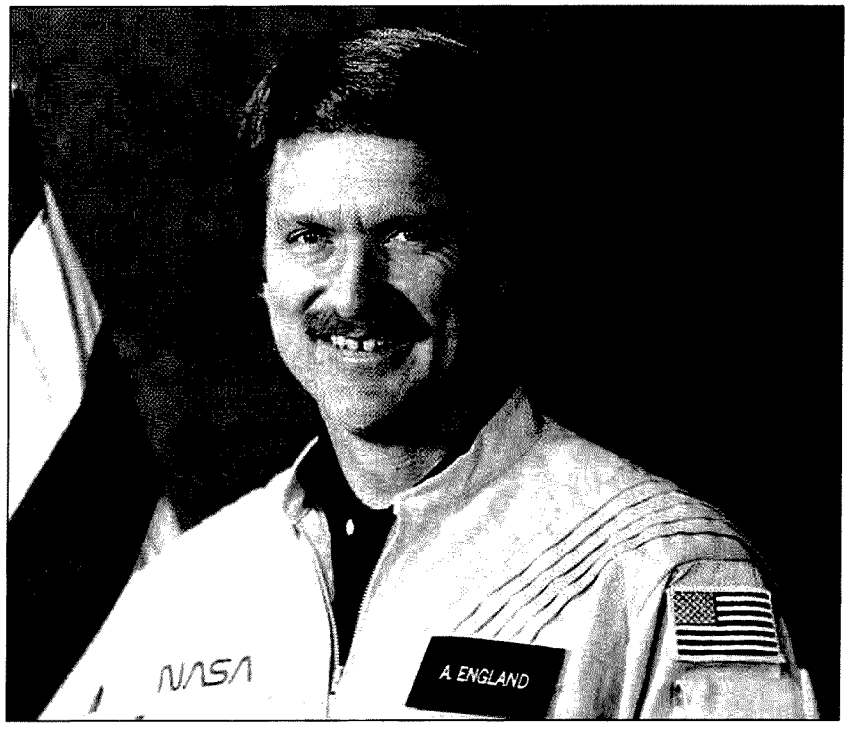
KW1O: Have you read of Don Stoner's proposal for a consumer packet service on six meters?

W0ORE: Yes, I have. I'm concerned that the service would be outside of amateur radio, essentially setting up a separate system of ham operators. Even worse, if we did establish a non-code digital class of license within the amateur service, I can see them being treated as second-class hams until they "grew up" and got a "real" ham license.

KW1O: Tony, are you on the bands much these days?

W0ORE: Well, I have more time than I have facilities. My neighborhood doesn't allow antennas, so I have to hide them. Most of them don't work, so I put 'em up and tear 'em down. I had a pretty good 40-meter wire beam up for a while, but the last hurricane we had wiped out the oak tree that was supporting it. I built a trap dipole, wound the coils and everything; it was a lot of pain and the antenna didn't work worth a darn. So I've taken that down and my next one is another wire antenna with an open-wire feed.

KW1O: You're using ladder line?

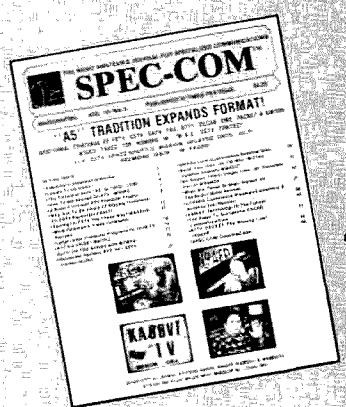


W0ORE: Oh, no, I'm going to make my own feedline. I've got about 30 of those little insulators and a big hunk of wire for it.

KW1O: You're one of a dying breed!

W0ORE: Well, I've got some spare time and don't know what to do with myself, so I thought I'd give it a try.

KW1O: I was surprised to read that your ham-in-space demo of slow-scan was the first instance of ground-to-spacecraft TV transmission. Doesn't the shuttle have two-way television?



W0ORE: I'm surprised too. Considering all of its facilities, the shuttle really should have two-way video. Part of the problem is the way the ground stations are configured...they just aren't set up for video. We're going now to a satellite-based commu-

HOT ROD ANTENNA
Achieve 1 or 2 db gain over ANY ¼ wave two meter telescopic antenna. The AEA model HR-1 Hot Rod™ antenna was designed by Dr. D.K. Reynolds (designer of the IsoPole) to deliver maximum performance for any hand-held transceiver with a BNC fitting.
The factory-tuned HR-1 is 20% shorter, lighter and places far less stress on your hand-held connector and case. It will easily handle over 25 watts of power, making it an excellent emergency base or mobile antenna. In the collapsed position, the Hot Rod antenna will perform like a helical quarter wave.
The Hot Rod antennas can be expected to make the same improvement to hand-held communications that the IsoPole brand antennas have made to base station operations. Why pay more when the best costs less?

nications system—part of it is in place right now—and that might handle video. We have a sort of FAX unit on the shuttle, but the thing weighs a ton; it's really low-quality. A real monster.

KW1O: Since your SSTV demo went so well, is NASA looking into replacing the FAX unit with a slow-scan system?

W@ORE: No, they're not. It's not that they don't appreciate the good results we had with SSTV, it's just incredibly expensive to design a unit and integrate it into the shuttle. The most expensive part would be updating all of the documentation for the orbiter . . .there are enormous piles of manuals.

KW1O: Had you tried SSTV before the flight?

W@ORE: No, I hadn't.

KW1O: It went pretty smoothly, didn't it?

W@ORE: Yes, very smooth. There's a lot to it, with all of the various formats and such. I practiced quite a bit on the ground with the local club station, and that helped. We had about a dozen two-way SSTV QSOs from space.

KW1O: Were most of those with youth groups?

W@ORE: Actually, no. The youth groups were tough for slow-scan; by the time we had established contact on voice and answered the kids' questions and so forth, the orbiter was out of range. The orbit was low to begin with, and there wasn't a lot of time for SSTV frames.

KW1O: Did the kids come up with crazy questions?

W@ORE: No, not at all. Mostly "What is it like?" and "What does it feel like?" and "What do you see?" They wanted to know which experiments were working best, and what we were finding out that we didn't know before. They were really good questions.

KW1O: How did the unpublished frequencies work out? Was there any trouble?

W@ORE: No, not too much trouble. There were a few guys on them that shouldn't have been, but it worked out just fine. On the published frequencies, an interesting thing happened. I started out by working like Owen did. I would listen for a minute or so, and then transmit all of the calls that I had heard during that minute. What happened was that nobody was stopping to listen to me! I would get some callsigns, and transmit them down, and the next minute these same guys would still be calling! I said, "Hey, this isn't going to work," and started doing it contest-style, acknowledging stations one at a time. That seemed to work much better. I also found that I really didn't need all of the channels on the radio. I think maybe two or three would do, so I could QSY if some ham had switched his receiver off.

KW1O: Gordon Fullerton made some QSOs. Is he psyched up for ham radio again? [Gordon once held a Novice license.]

W@ORE: Well, I tried to have that happen. He enjoyed making the contacts, but I don't think he's going to run out and get a license.

KW1O: Tony, it's been great talking with you.

W@ORE: Likewise, Perry. 73!■

Two to Ten

Plug into the excitement of 10 FM—your HT is the key!

Ten-meter FM is a unique operating experience. It combines the convenience of channelized operation with frequent DX band openings. Mobile operation is very successful on 10-meter FM, as just a few Watts of transmitter power are needed for direct DX contacts. Furthermore, a number of high-performance repeaters are now in service to support 10-meter FM operation worldwide.

While many of the new HF transceivers feature FM as a standard or optional mode, the availability of inexpensive low-power equipment for mobile or portable operation is somewhat limited. A number of hams have successfully adapted low-band commercial FM rigs and CB transceivers to 10-meter FM operation. Often, however, one or more of the following desirable features is found to be difficult to implement in such a conversion: tuning of all 10-meter FM channels, direct and repeater mode selection, good quality audio, and clean limiting (good noise rejection) in the receive mode.

This article presents an alternate approach to 10-meter FM equipment—a 2-meter-to-10-meter transverter. "2 to 10" is designed to translate the operation of a 2-meter FM transceiver to 10 meters. All the features of the 2-meter transceiver (synthesized tuning, memory, scanning, touchtone™ pad, etc.) can be used on 10 meters. 2 to 10 includes both direct and repeater offset modes. The inherent audio quality of the FM transceiver is preserved in its translation to and from 10 meters. The transverter operates from 12 to 14 V dc, making mobile and portable operation straightforward. 2 to 10 was designed with 2-meter HTs in mind, but it should work with any modern 2-meter FM transceiver with a low power output in the 150-mW-to-1-W range.

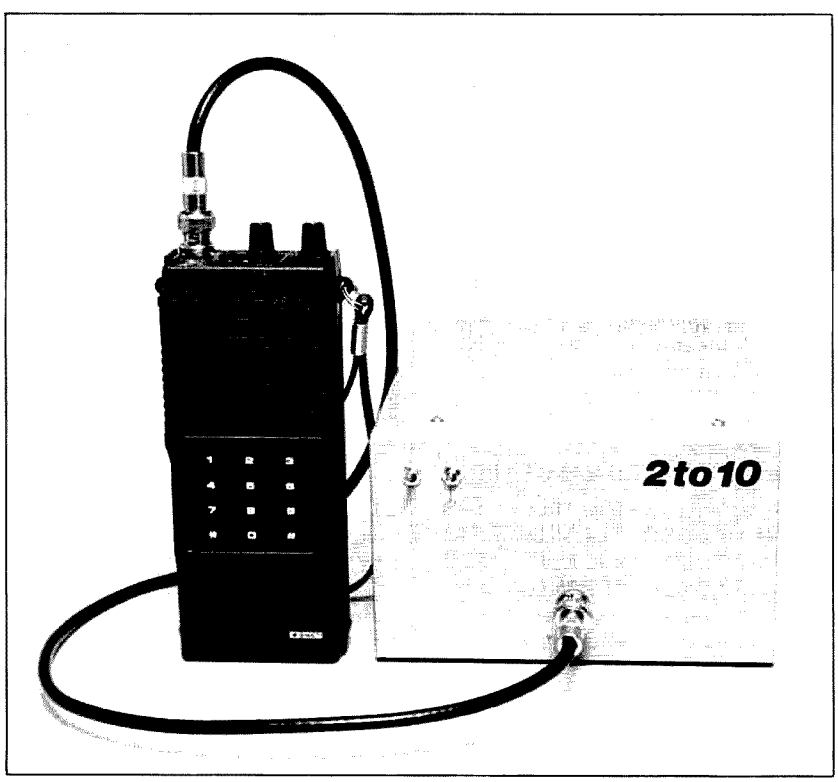

Photo A. 2 to 10 is a transverter that places your 2-meter FM rig on 10-meter FM.

2 to 10 uses low-cost components which are readily available from suppliers that cater to the individual rf experimenter. Construction costs for 2 to 10 run about $65, not counting junk-box discounts. If you already have a 2-meter transceiver, 2 to 10 can be an effective and inexpensive approach to getting on 10-meter FM.

Operation

When using 2 to 10, the 2-meter FM transceiver is placed in the direct (simplex) mode and is set for low power. The 2-meter transceiver is operated in the frequency band of 146.40–146.48 MHz. 2 to 10 translates this frequency band to 29.60–29.68 MHz for direct operation and offsets the transmit frequency −100 kHz for repeater operation. Note that the repeater offset is done by 2 to 10; the 2-meter rig is *always* operated in the direct (simplex) mode. Increasing the frequency setting on the 2-meter transceiver increases the operating frequency on 10 meters a like amount. (Note that this is different from satellite translator operation; do not get confused.)

Block Diagram

Let's first look at 2 to 10's block diagram, Fig. 2. We will then look at the circuits in

each block in detail. A dummy load is provided to present a reasonable match to the 2-meter transceiver during transmit. T-R switch circuitry senses the presence of 2-meter rf power and switches 2 to 10 to the transmit mode. A small sample of 2-meter rf is mixed with the local oscillator (116.80 MHz for the direct mode or 116.90 MHz for the repeater mode) in the transmit mixer, developing a difference frequency at 10 meters. Tuned circuits in the mixer and preamplifier stages reject other unwanted mixer outputs. The driver and final-amplifier stages boost the 10-meter output to about 3.5 Watts. The rf output is then low-pass-filtered and output at the 10-meter connector.

In the receive mode, the incoming 10-meter signal is mixed with the local oscillator (always 116.80 MHz for receive) in the receive mixer, developing a sum frequency output on 2 meters. This signal is bandpass-filtered and applied to the 2-meter connector.

The local-oscillator chain consists of a 58.4-MHz oscillator, a doubler stage, and switching to route the local oscillator to either the transmit or receive mixer. One or two crystals are switched in to control the oscillator, depending on the mode of operation. All T-R and rf switching is solid state.

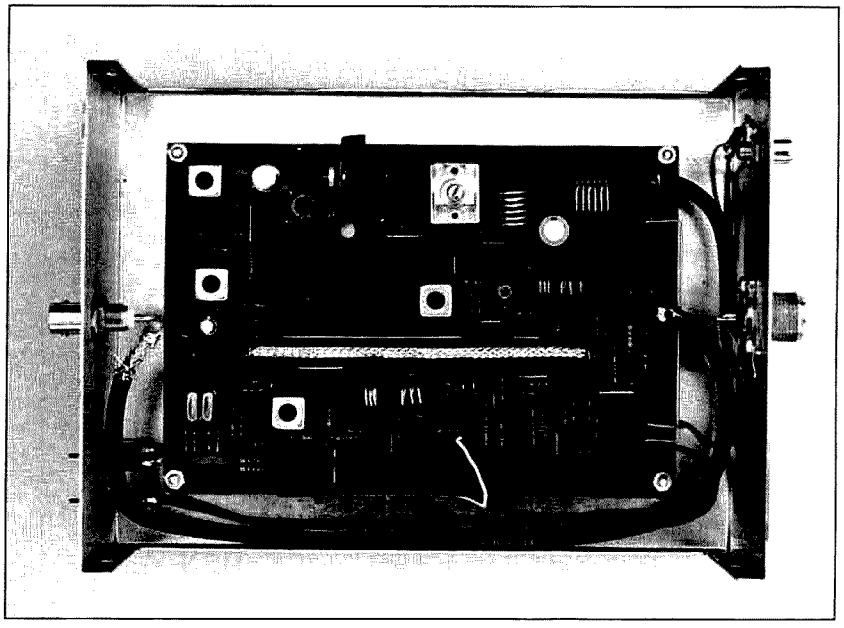

Photo B. Interior view of 2 to 10.

Dummy Load and T-R Voltages

For the following discussion, please refer to the schematic diagram, Fig. 3. R1 and R2 provide a dummy load for the 2-meter transceiver. When transmitting, R38 delivers 2-meter rf to the clamp network consisting of CR15-CR18. These diodes level the rf voltage detected by CR19 and C35 for various input power levels within 2 to 10's operating range. The detected rf switches Q8 on, which switches Q9 on to provide +T voltage. At the same time, Q8 switches Q10 and Q11 off, dropping the +R voltage. During receive, Q8 and Q9 are off and Q10 and Q11 are on, so that +R voltage is provided instead of +T. The diodes used in the T-R circuit are 1N914s or equivalent. The MPS2222 and MPS2907 are inexpensive plastic-package versions of the 2N2222 and 2N2907.

Transmit Chain

During transmit, R3 supplies 2-meter rf to clamping diodes CR1 and CR2, which provide a leveled rf signal of about 1.6 V p-p. This signal is further attenuated by the R4-R6 network and applied to gate 1 of Q1, a 3N211 dual-gate MOSFET mixer. About 3.5 V p-p of local-oscillator voltage is applied to gate 2 through C2. C4 and T1 resonate at 29.6 MHz, the 10-meter difference-frequency output of the mixer. The signal level across C4-T1 is about 600 mV p-p. Q2, an MPS918 rf transistor, provides about 20 dB of voltage gain, and C36-T2 provide additional filtering. Driver Q3 provides another 17 dB of gain. Broadband transformer T3 provides a suitable match between the collector of Q3 and the base of Q4. R14 helps ensure driver stability, as the 2N3866 is a high-gain device. Q4 further amplifies the 10-meter FM signal to about 3.5 Watts. The transistor chosen here is a rugged and inexpensive 2SC1909 which is used in many CB rigs. Broadband transformer T4 provides a suitable match between the 50-Ohm antenna load and the collector of Q4. C13-C15 and L1-L2 form a low-pass filter to attenuate harmonics of the 10-meter output.

Receive Mixer

The incoming 10-meter signal is first low-pass-filtered by C13-C15 and L1-L2, which attenuates unwanted signals above 30 MHz. C16 lightly couples the incoming signal from the low-pass filter to resonant circuit C17-L3. This type of coupling has a high-pass-filter characteristic, which helps reject signals below 10 meters. CR4-CR5 clamp the rf voltage at gate 1 of Q5 during transmit to avoid damaging the transistor. Gate 2 of Q5 is driven from the local oscillator through C37. Drive level is about 4 V p-p. The drain of Q5 drives a double-tuned bandpass filter consisting of L4-C21 and L5-C22. The double-tuned filter attenuates local-oscillator feedthrough and other unwanted signals

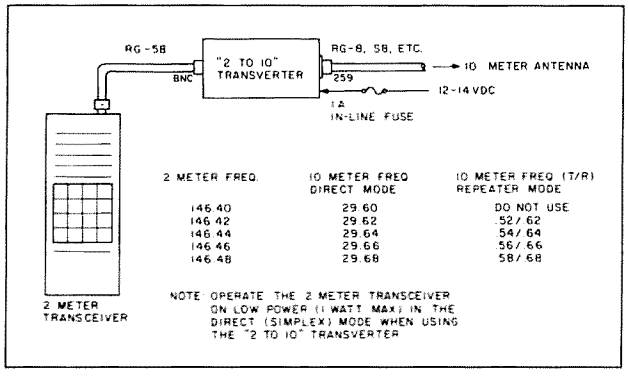

Fig. 1. 2 to 10 hookup.

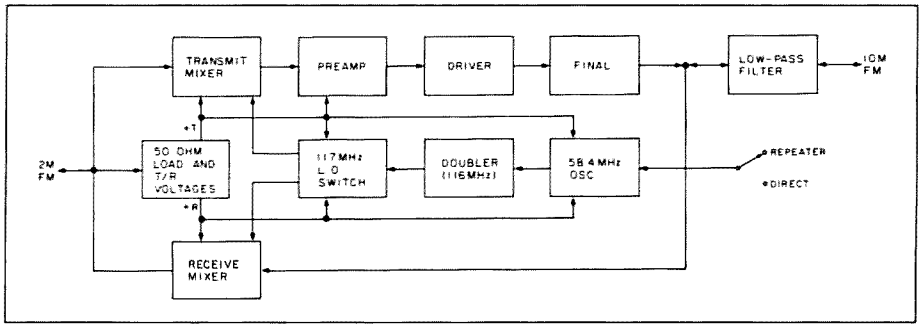

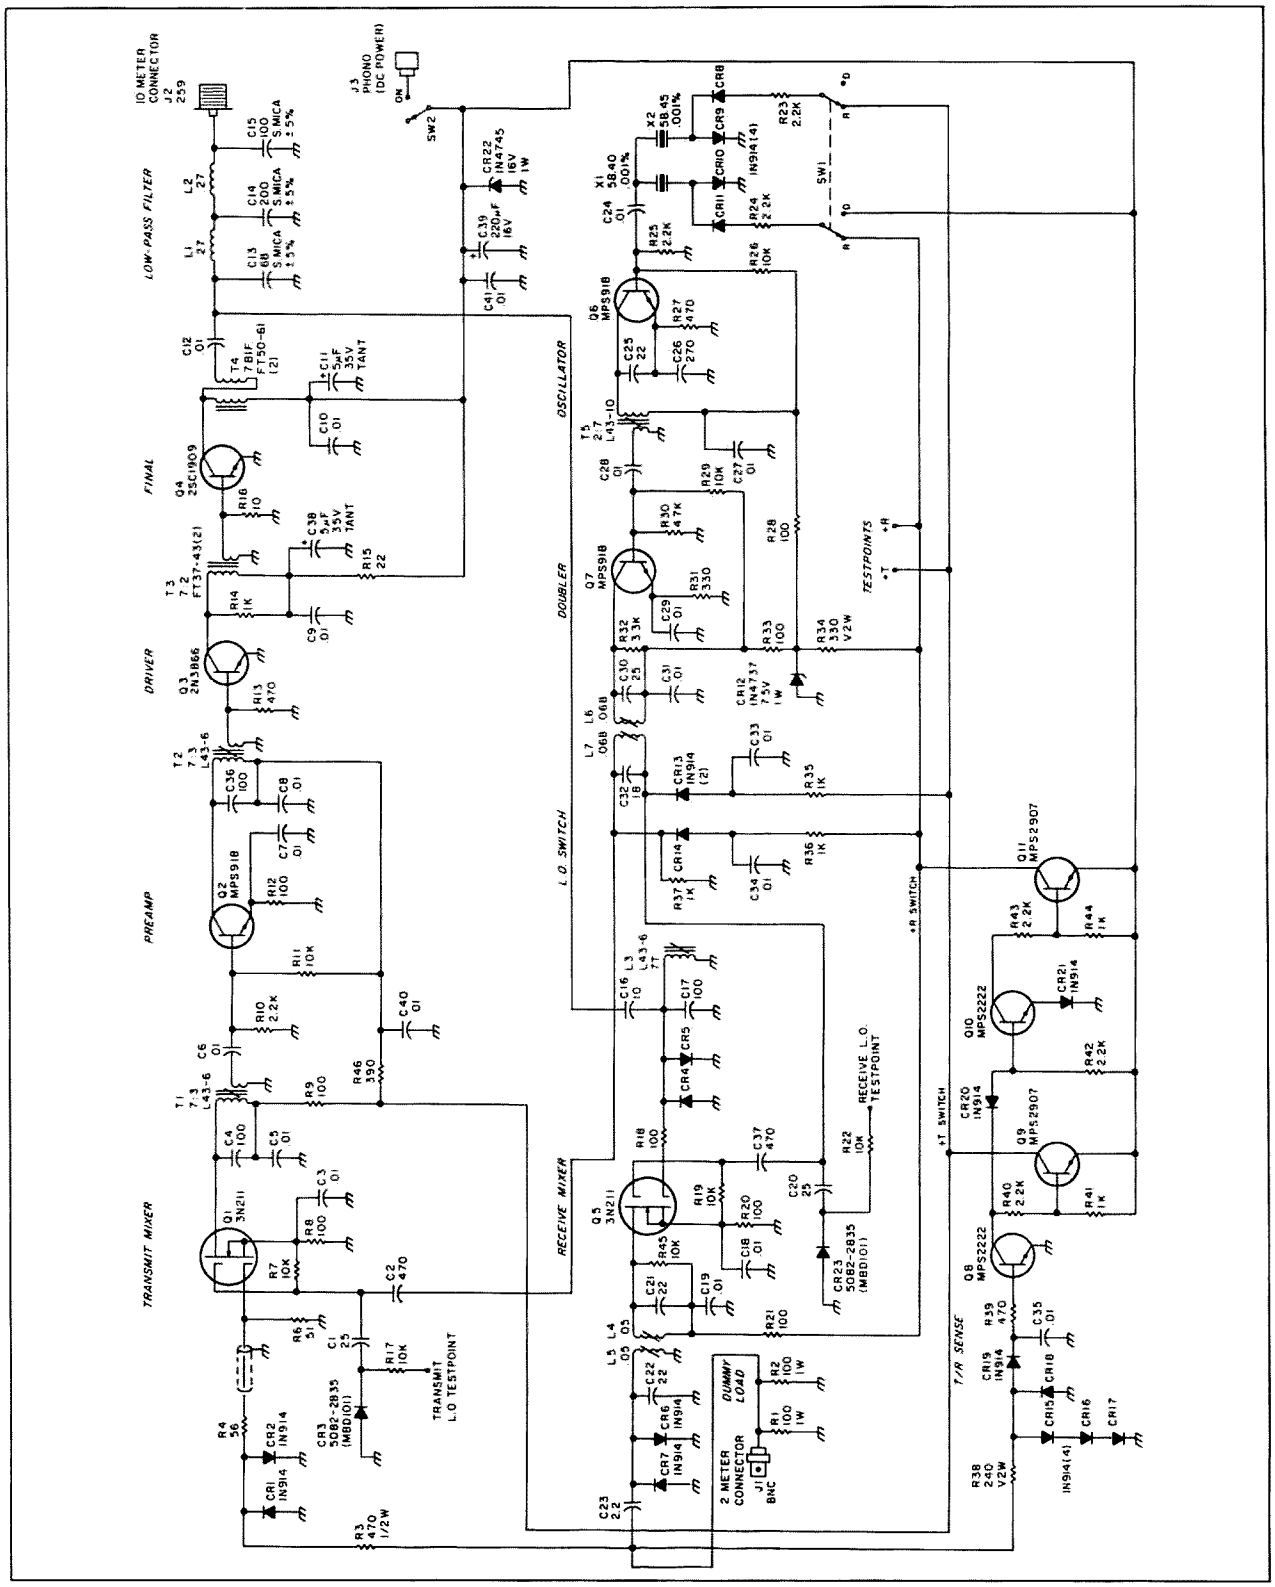

Fig. 2. Block diagram.

1. Unless otherwise marked: resistors are ±5% carbon film or carbon composition, 1/4 W; capacitance values greater than 1 are in pF, less than 1 are in uF; capacitance values between 1 and 82 are 500 V dc NPO ceramic, ±5%; capacitance values between 100 and 1800 are 500 V dc Y5P (temperature stable) ceramic, ±10%; capacitance values between .001 and .1 are 50 V dc Z4V (general purpose) ceramic, + 80, −20%.
2. Crystals are ±.001%, third overtone, series resonant, HC25/U holder.
3. See Fig. 8. for rf inductor and transformer data.

Fig. 3. Schematic.

in the mixer output before they reach the 2-meter receiver and cause intermodulation problems. C23 lightly couples the mixer output to the 2-meter connector. CR6-CR7 clamp the rf voltage fed back toward the drain of Q5 during transmit. The light coupling and clamp circuits on each side of Q5 allow 2 to 10 to switch from receive to transmit without needing isolation relays.

The conversion gain through the receive mixer is about 0 dBm, due mainly to the light coupling in and out. I wanted no conversion gain through the receive mixer to avoid overdriving the 2-meter receiver and creating intermodulation problems. I felt this was especially necessary for HTs, as they must often sacrifice "strong" front ends for low power drain and compactness. On-the-air testing with 2 to 10 using my ICOM IC-2AT has demonstrated satisfactory sensitivity and no evidence of intermodulation. A signal of −113 dBm (0.5 uV) at the 10-meter input of 2 to 10 will cleanly break the squelch of my 2AT.

Local-Oscillator Chain

Q6 operates as a grounded-base 58.4-MHz Colpitts oscillator. The ground path for the base of Q6 is through the series resonance (3rd overtone) of the crystal selected to control the oscillator. Adjusting the slug in T5 allows a slight frequency adjustment of the oscillator for "netting" it on frequency. CR9 and CR10 operate as current-controlled switches that select either crystal X1 (58.40 MHz) or X2 (58.45 MHz). When switch SW1 is in the direct mode, X1 is selected to control the oscillator in both transmit and receive. When SW1 is switched to the repeater mode, X1 is selected for receive by the +R voltage and X2 is selected for transmit by the +T voltage (providing the needed transmit offset).

The output of the 58.4-MHz oscillator is doubled by the Q7 stage. The collector of Q7 drives a double-tuned 117-MHz filter consisting of C30-L6 and C32-L7, which attenuates the 58.4-MHz fundamental and the unwanted oscillator harmonics. This is necessary to suppress unwanted responses in the mixers.

CR13 and CR14 are used as current-controlled switches to route the 117-MHz local-oscillator output to the transmit or receive mixer. In transmit, CR13 conducts, rf grounding the receive-mixer side of C32-L7 through bypass capacitor C33. Local-oscillator voltage is then routed from the ungrounded side of C32-L7 to Q1. During receive, CR14 conducts, rf grounding the transmit-mixer side of C32-L7 through C34. Local-oscillator voltage from the receive side of C32-L7 is now supplied to Q5. C20-CR23-R22 provide a dc sample of the receive-mixer local-oscillator voltage for tune-up and testing. C1-CR3-R17 provide the same function for the transmit-mixer local-oscillator voltage.

Components

As I mentioned earlier, the components used in 2 to 10 are readily available. Fig. 4 provides a listing of mail-order distributors for the components in 2 to 10. I recommend that you avoid substitutions. One exception would be C23. You can use a 2-pF silver-mica capacitor if you have difficulty finding a 2.2-pF NPO ceramic capacitor.

Construction

Above 100 MHz, the circuit board itself becomes an important component. For this reason, I strongly recommend that you duplicate the circuit-board layout shown in Fig. 5. Fig. 6 provides recommended hole sizes and corresponding number drills. Use .062"-thick G-10 glass-epoxy circuit board with 1-oz. copper on one side. Be sure to fully etch the board and inspect it carefully before beginning construction.

Rf Inductors and Transformers

I recommend winding all transformers and inductors before you start to load the circuit board. The winding data is provided in Fig. 8. All air-core inductors are wound on screw mandrels. You can pick up a set of screws (2- to 3-inch lengths) at your local hardware store. Radio Shack markets a packet of magnet wire (278-1345) which includes one roll each of 22, 24, and 30 gauge. The enamel on this wire can be stripped with hot solder, so it is ideal for rf-coil and transformer winding. Notice that T4 is bifilarly wound. I used a variable-speed electric drill (go slow!) to twist a pair of wires to about 5-6 turns per inch. Epoxy the two stacked cores used in T3 and T4 together before winding. Use an ohmmeter to identify each winding of T4 at both ends. I painted a small dab of black enamel on each end of the primary winding for later identification.

All slug-tuned transformers and inductors are wound on L43-style Micrometals forms. The primaries of these transformers and inductors are close-wound single-layer solenoids. They are wound at the bottom of the form. Secondary windings are also single-layer solenoids, wound over the primary windings at the bottom of the form. Note that there are 3 pins on one side of the L43 form and 2 pins on the other. A primary winding will always have its leads terminate on the side with 2 pins; the leads of a secondary winding will terminate on the outer posts of the 3-pin side. The circuit board is keyed this way, so do it right.

All air-wound coils are made from 18-gauge bus wire. As mentioned, the mandrels make winding these coils a snap. Dimensions are also given in millimeters, in parentheses, if you are more familiar with the metric system.

Circuit-Board Loading

Fig. 7 details the component placements on the circuit board. Photo B will also help (slight changes have been made since the photo was taken—note that C13 is now a fixed-value capacitor). I prefer to first install the jumper wires and the coax between the 2-meter input area and Q1. Note that the coax is RG-58 with the outer insulating jacket removed. Watch diode polarity and transistor orientation carefully. Keep leads short. Be extra careful in installing T4. Note that it is hooked up as a step-up autotransformer. Install Q1 and Q5 in the circuit board after all other components have been installed. This will reduce the chance of damaging these static-sensitive parts.

Parts List

Component	Supplier #
Crystals	2
MPS transistors	3,4
2SC1909	6
3N211	5

Fig. 4.

All circuit-board components are installed through the top of the board except R23, which is tack-soldered across L6 on the bottom (solder side) of the board. Note that resistors R17 and R22 are standing up as test points. Make a small loop in the top lead of these resistors. Note the ground reference points next to these resistors. Make small bus-wire loops for these points. It is best to use 1k resistors as test points for the +R and +T voltages. This will avoid a catastrophe if the test points are shorted together.

Make the hook-up wire leads going to and from the circuit board to SW1 about 6 inches long. Install one end of a 4-inch length of RG-58 at the 2-meter input/output point on the circuit board. Use a half loop of 22-gauge bus wire to both ground the coax shield and strain-relief it. Install a 13-inch length of RG-58 at the 10-meter input/output point of the circuit board. Be sure to ground and strain-relief this coax also.

Be sure to install a lightweight finned heat sink on Q4. Depending on the heat-sink design, you may need to clip one fin off the bottom of the heat sink to avoid mechanical

interference with C10 and C11. Secure T3 and T4 to the circuit board with RTV or Silastic compound if you are going to operate mobile.

After the circuit board is loaded, check carefully for solder bridges and cold solder joints. I found that shining a desk lamp through the component side of the circuit board helped in looking for solder bridges.

Enclosure

2 to 10's enclosure is made from a 6" wide by 3.5" high by 8" long aluminum minibox (Bud CU-3009A). Use the general layout shown in the photographs. I strongly recommend that you "key" the 2-meter connector by making it a BNC and use a 259 connector for 10 meters.

The circuit board is held in place with 4-40 screws, using 0.75"-long pieces of aluminum tubing slipped over each screw as spacers. The tubing has an inside diameter a little larger than 0.125 inches. Coordinate the mounting-hole locations of SW1 and SW2 with the length of the spacers to avoid mounting interference between the switches and the circuit board. Ditto on the connectors. Use bus wire to ground the coax shields at the connectors. Dress all wiring down one side of the chassis so that the circuit board can be stood up vertically for tune-up and testing.

Make a final careful check of the chassis wiring. Be sure all connectors and switches are tight.

Test Equipment

The equipment required to tune up 2 to 10 includes a 12–14-V-dc regulated power supply, a 2-meter transceiver, a sensitive 150-MHz counter, a FET multimeter or DVM, a sensitive swr meter and dummy load, a 29.6-MHz signal source, a tuning dowel, and a plastic tuning wand. Access to a good 30-MHz scope is desirable. A wide-range step attenuator(s) is also very useful. Refer to Fig. 9 for construction details of a suitable 29.6-MHz source and tuning dowel.

Coil Knifing

By now you may have noticed, and possibly with some concern, that there is not a single trimmer capacitor used in 2 to 10. This is deliberate. If you are going to use trimmer capacitors above 100 MHz, they must be good ones. Such trimmers are expensive and sometimes difficult to find. To avoid trimmer problems, I avoided using trimmers!

OK, how do we adjust those double-tuned circuits in the outputs of Q5 and Q7? We use a technique called knifing. Basically, we adjust the value of an inductor by stretching it out or compressing it. While it may sound crude, it is an excellent technique. Knifing is used extensively to adjust tuned circuits in TV tuners, broadcast radios, VHF/UHF ham equipment, etc. When done correctly it is both precise and stable. Best of all, it's inexpensive and easy to duplicate.

So much for the sales pitch. You need two tools for coil knifing—a tuning dowel and a stiff plastic tuning wand. A tuning dowel is a wooden (or plastic) stick with a ferrite slug on one end and an aluminum ring on the other. Bringing the ferrite-slug end of the dowel near the end of an air-core inductor will increase its inductance, whereas bringing the aluminum-ring end near the inductor will decrease its inductance. By monitoring a test point related to the tuning of the inductor, a decision as to how to adjust the dimensions of the inductor can be easily made by using the tuning dowel. You can think of the tuning dowel as a temporary inductor core.

Let's consider an example, the tuning of L6-C30 and L7-C32, the double-tuned collector load of Q7. The top end of R22 provides a dc test point for tuning (receive). Preset L6 by compressing it to a length of 0.20" (5 mm) and stretch L7 to a length of 0.25" (6.4 mm). With oscillator Q6 running, some dc voltage will be detected at R22 (0.5–2.25 V dc). We will tune for peak voltage.

Bring the ferrite-slug end of the dowel into the Q7 end (physical circuit-board layout) of L6. Note if the test-point voltage tends to rise or fall. If the voltage rises, compress L6 a bit and recheck the voltage. If the voltage decreased as the ferrite slug was brought near

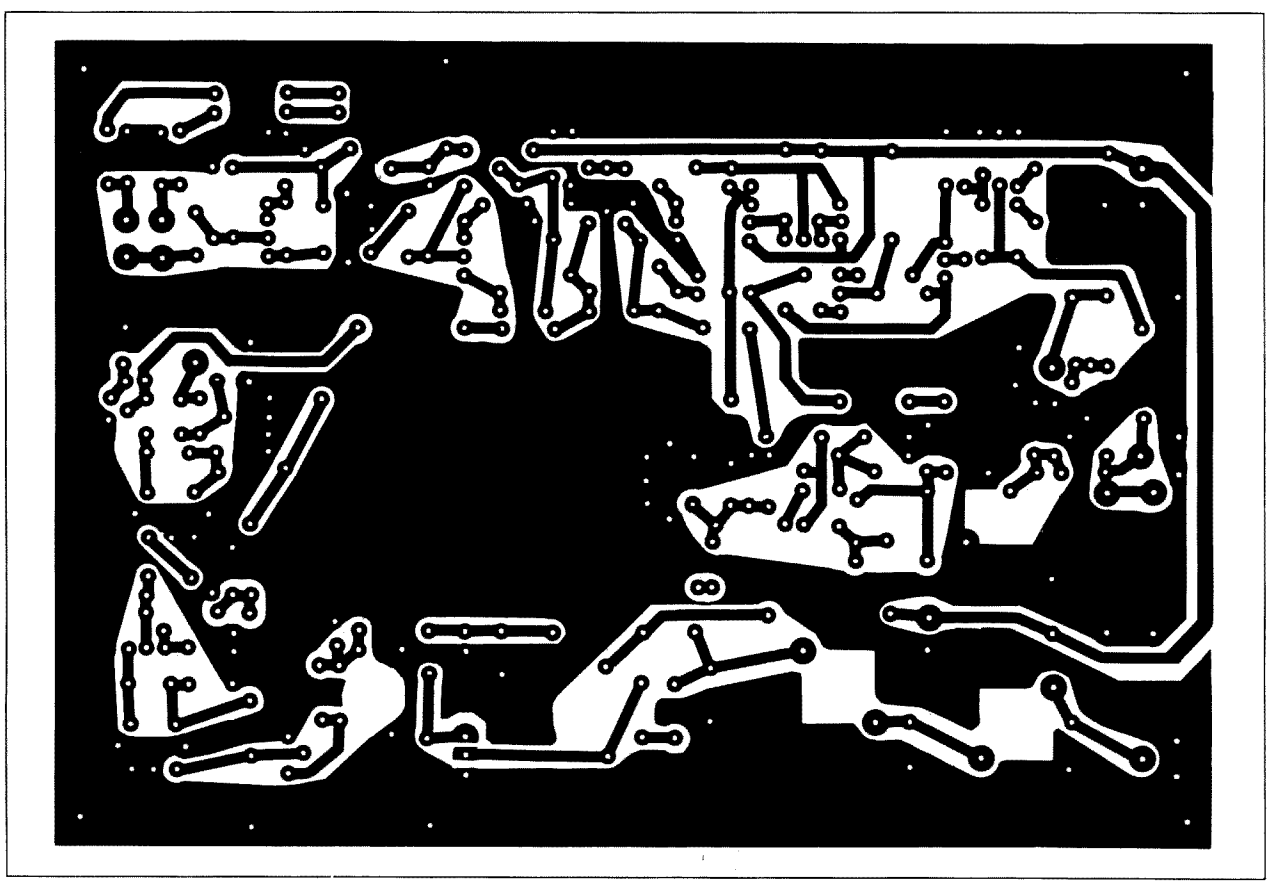

Fig. 5. Circuit-board artwork.

L6, try the aluminum-ring end. If the voltage rises, then stretch the coil a bit and recheck. When the coil is tuned on resonance, the test-point voltage will tend to decrease when either end of the dowel is brought near the end of the coil. After L6 is tuned, peak L7. The tuning of the two coils causes some interaction, so repeat the tuning process a couple of times. Once the coils are tuned closely, you can dispense with the tuning dowel and compress and expand the coils slightly with the plastic tuning wand (knife) while watching the test-point voltage. Push the coil far enough past the peak to take a physical "set" and let off. After about a minute of experience, you will be able to tune a coil by knifing about as fast as you could adjust a tuning slug or trimmer!

Tuning Setup

Hook up the regulated dc supply to the transverter, being sure to use a 1-Amp in-line fuse. Hook the 2-meter transceiver to the 2-meter connector of 2 to 10. Set the transceiver on low power (1 Watt maximum) and set it in the direct (simplex) mode. Tune to 146.400 MHz. Hook a dummy load to the 10-meter connector of 2 to 10 through a sensitive swr meter. Set the meter to read forward power.

T-R Voltage Check

Turn both the dc supply and 2 to 10 on. A lack of smoke at this point is a good sign. (You did get the polarity correct?) Check the +R test point. It should read within one volt of the dc supply voltage. The +T voltage should be off at this point. Bridge a 1k resistor between the supply voltage and the junction of CR19-C35-R39. Note that +T is now on and +R is off. Remove the 1k resistor.

Oscillator-Doubler Tune-Up

Back the tuning slug out of T5 so that it is about 0.20" (5 mm) above the top of the shield. Monitor the R22 test point. As the slug is slowly screwed in, the voltage at R22 should "jump" on, indicating oscillation. Bring the counter-sense loop near Q6. Adjust the slug for 58.400 MHz. Now tune L6 and L7 for a peak reading of at least 2 V dc (this corresponds to about 5 V p-p of rf) as discussed in the "Coil Knifing" section. Bring the counter-sense loop near L7. You should read 116.800 MHz. Fine-tune T5 as needed to obtain a 116.800-MHz reading at L7.

Material is green G-10 epoxy-glass, 0.062-inch nominal thickness, 1-oz. copper, single-sided. Reference hole A is unmarked.

Receive-Mixer Tune-Up

To adjust the receive mixer, a suitable 29.600-MHz source is needed. If you have access to a commercial signal generator with an adjustable output (down to 1 uV), use it. Otherwise use the source shown in Fig. 9. A step attenuator (or set of attenuators) with a 130-dB range is the best way to interface 2 to 10 with the source. If an attenuator is not available, leave 2 to 10 hooked to the dummy load and put a 2" bus-wire antenna into the BNC connector on the source. Move the source just close enough to the transverter so that the 2-meter receiver noise begins to quiet. (The bottom of 2 to 10's case is off for tuning.)

Remember, an increasing signal level quiets the background noise in an FM receiver. You adjust 2 to 10's receive mixer by tuning to "quiet" the noise output of the 2-meter receiver.

Start by compressing L4 to a length of 0.15" (3.8 mm) and stretching L5 to a length of 0.25" (6.4 mm). Back the slug in L3 out until it's about 0.05" (1.3 mm) above the top of L3's shield. You should be able to hear the 2-meter receiver quiet when you turn on your 29.600-MHz source. Start at 30 uV if you are using a signal generator, or switch in about 88 dB of attenuation if you are using the source in Fig. 9 with attenuators. Keep reducing (or increasing, if necessary) the signal level until some quieting is heard in the 2-meter receiv-

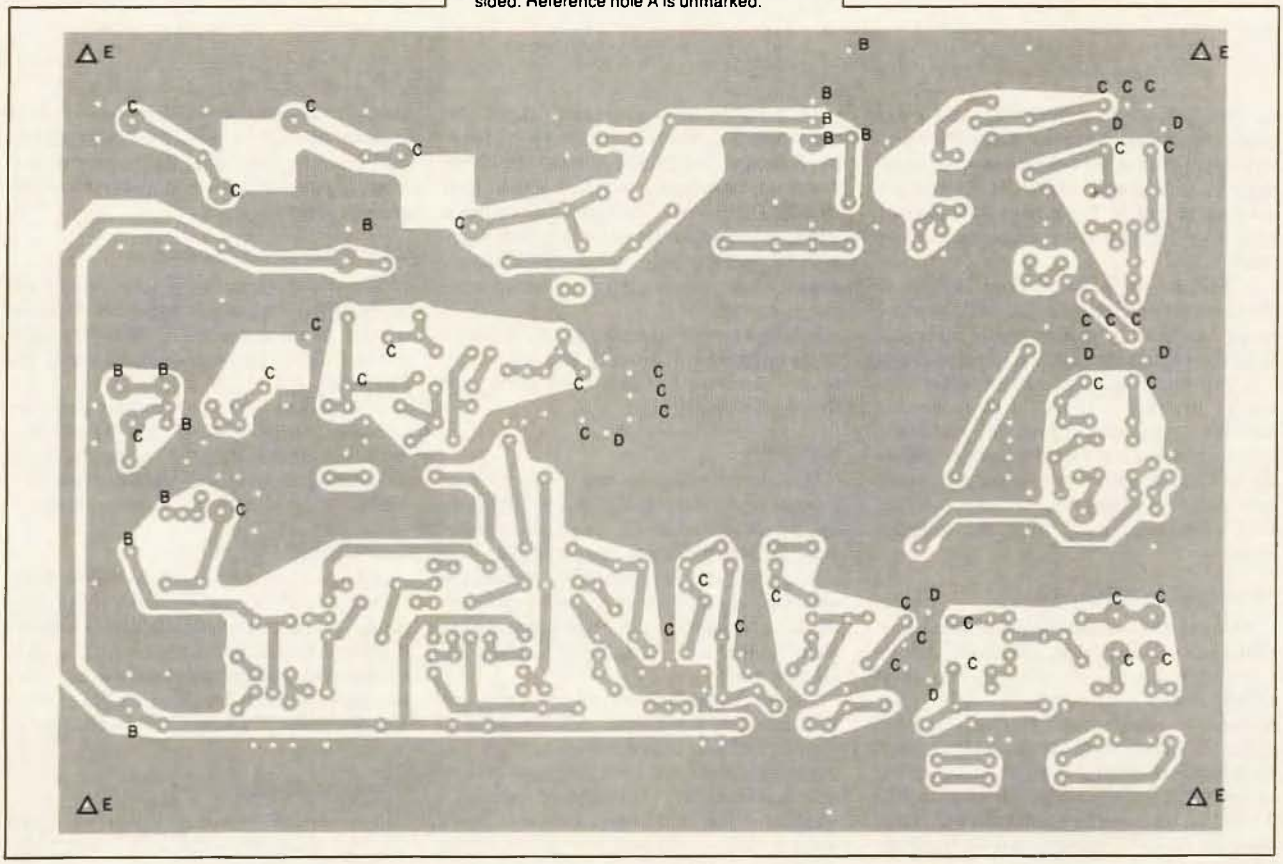

Fig. 6. Hole-size data.

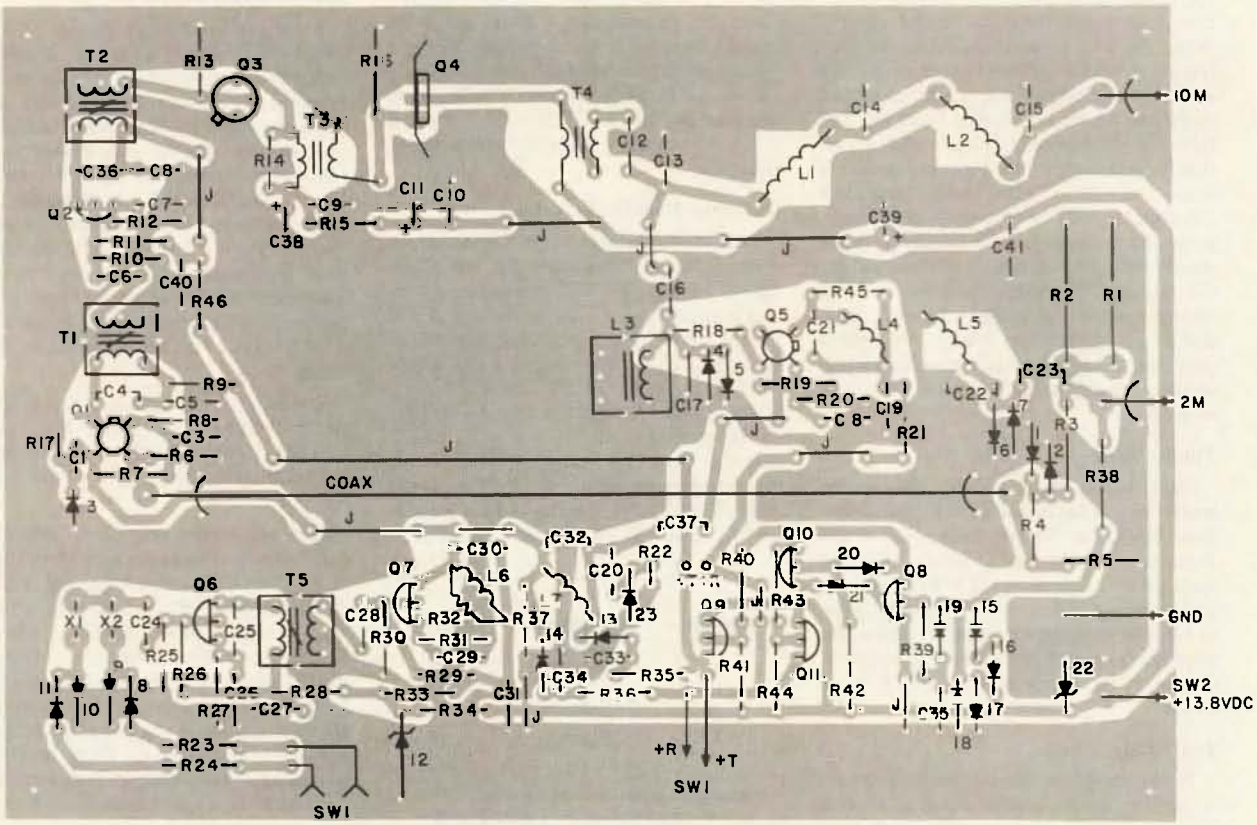

Fig. 7. Component placement.

er. Now adjust the tuning slug in L3 for greatest quieting. Keep reducing the input signal level as needed so that you have some noise to work against. Knife L4 for greatest quieting, then L5. These coils will interact some, so tune them in sequence several times.

If you are using the antenna instead of the attenuator with the 29.600-MHz source, simply move it to adjust signal strength. If you are using this method, I recommend that you touch up your receive-mixer tuning by hooking 2 to 10 to your 10-meter station antenna and by moving the source at least 30 feet from your transverter. Prune the antenna on the source (as needed) to reduce signal strength. I suggest that you do this final adjustment after tuning the transmit chain.

Transmit-Chain Tune-Up

Set 2 to 10 in the direct mode. While monitoring the +T test point, key down your 2-meter transceiver (on low power!). You should see +T switch high. With your transceiver keyed, confirm that you have about 1.5 V dc on the R17 test point. You will have some forward power showing on the swr meter. Carefully peak the tuning slugs in T1 and T2 for maximum output power. Then back the slug in T1 slightly out (counterclockwise) until the power just begins to decrease. Expect 3.5 Watts of output power. Key down your 2-meter transceiver and check the transverter's output frequency with the counter. It should read 29.600 ±.001 MHz. Now switch to the repeater mode. It should read 29.500 ±.001 MHz. Touch up the oscillator tuning so both readings fall within their tolerance. Notice that they tune up and down together. (You did use .001% tolerance crystals, didn't you?)

If things have worked out so far, welcome to 10-meter FM! If you run into any snags, review the theory of operation section for troubleshooting hints.

Operation

It is useful to tape a small card to your 2-meter rig (or the top of your 2 to 10) listing the 2-meter-to-10-meter frequency conversions for both direct and repeater modes. It is also a good idea to prominently include the note: *Operate the 2-meter rig on low power in the direct (simplex) mode when using the 10-meter transverter*. Remember: Garbage in, Garbage out!

2 to 10 draws about 50 mA in receive and less than 1 A in transmit. Always use a 1-Amp in-line fuse in the dc power lead going to the transverter. The 2SC1909 used in 2 to 10's final amplifier is reasonably forgiving of temporary load mismatches. However, don't abuse it. There is no reason to accept an swr greater than 1.3:1 since operation is quite narrowband. The lightweight heat sink used on the final is fine for the 1-minute-on, 1-2-minutes-off type of service that is typical of FM conversations. Beef up the heat sink if you are going to operate in transmit for long periods of time.

Direct/Repeater Operation

Most direct operation is found on 29.600 MHz. This frequency is monitored by many people, and a number of VHF/UHF repeaters have added crossband capabilities to this frequency.

The normal 10-meter repeater pairs are .52/.62, .54/.64, .56/.66, and .58/.68. Remember, *always* leave the 2-meter rig in the direct (simplex) mode. Use the DIR/RPT switch on the transverter to change modes!

Base-Station Operation

All you need is a regulated 12–14-V-dc, 1-A supply and a good vertical antenna. I am using a Cushcraft AR-10 with excellent results. Many people cut down CB ground planes with good success. As there is often a significant loss due to cross-polarization on 10 meters, it's best to use some type of vertical.

Mobile Operation

You can run 3–4 feet of coax between your 2-meter rig and 2 to 10, so mobile installation is fairly flexible. You will want comfortable access to the ON switch and the DIR/RPT

switch of the transverter. I prefer to take dc power from a point that disconnects automatically when the motor is cranked. This reduces the chance of damage due to an electrical transient. If you get a case of alternator whine, try a dc power filter such as the Radio Shack 270-050. 2 to 10 was not designed for operation at extreme temperatures. I suggest an operating temperature range of 40–100° F. On very cold or warm days, let 2 to 10's temperature normalize before operating.

Choosing a good antenna is the key to success for 10-meter mobile operation. If you already have a Hustler antenna, get the 10-meter resonator and use it. It's OK to trim down a CB antenna, but start with a good one! I am very skeptical of short antennas. I hope some of you antenna designers out there will work up a set of effective antennas for 10-meter mobile FM—maybe a good DDRR roof mount. Oh yes, avoid using crummy CB coax.

Coil Reference #	Nominal Inductance	# of Turns-N	Wire Gauge AWG.	Inside Coil Diameter D	Coil Length L	Spacing S	Mandrel

T5 Primary—7 turns of #30 (.25) close-wound at the base of a Micrometals Inc., L43-10 form, .34 uH; secondary—2 turns of #30 (.25) wound over primary.

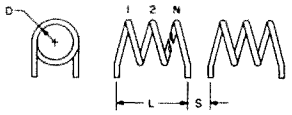

Fig. 8. Rf inductor and transformer data.

From Here

Ten has always been my favorite HF band because it provides local rag-chewing, surprising low-power DX contacts, and many operating modes. 10-meter FM ices the cake. I hope I have encouraged you to get on 10-meter FM some way. If you would like to write and ask a question about 2 to 10, please include an SASE. Please hold phone calls to Friday evenings, 7:30 to 10:30 p.m. Central time. No collect calls, please! See you on 10-meter FM. ■

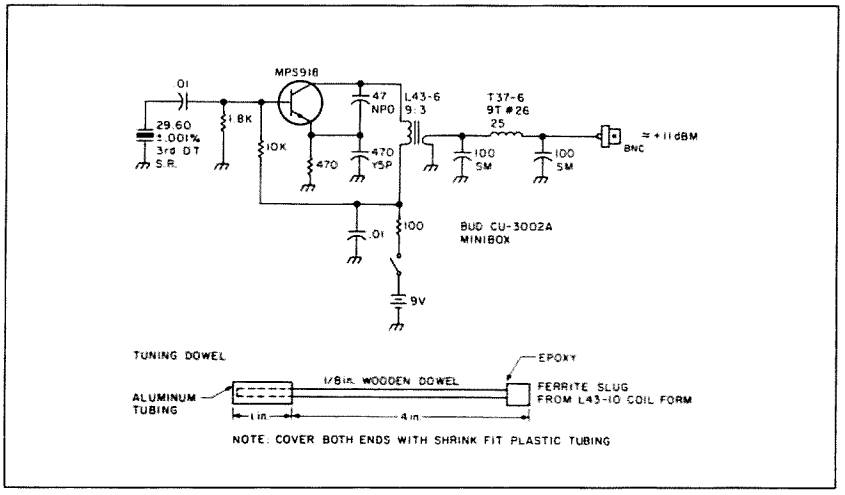

Fig. 9. 29.600-MHz alignment oscillator.

Jean Shepherd K2ORS

Some Guys Make It

. . . . . And then there's us

While digging through a pile of vintage 73s the other day, we came across this gem by Jean Shepherd K2ORS. It originally appeared in the December, 1963, issue. Since it's already paid for and it's still as funny as the day we bought it, we thought you might like to see it again.—Eds.

You know, when you really step off a cliff, you know you've done it. It's just like looking out from the observation tower at the Empire State Building, and suddenly you're in midair and you know that there's no going back. I mean, it's a great flight, while it lasts.

It's maddening. You notice that up and down the street, the guys in the big Cadillacs never get tickets? Have you ever yet seen a ticket on a fat Mercedes? Let me tell you, I used to come back with my motor scooter decorated like a Christmas tree. You know, all those little green tags hanging like tinsel all over it. And in front of me would be a tagless Cadillac, and behind me a tagless Mercedes. Both parked there since last Easter. My scooter. . .I'd slow down, and the fuzz would be running alongside me, tying 'em on.

Well, that goes in all directions. There are guys who always get it you-know-where, and there are guys who don't. It's just that way. Now I don't know how it's set. I don't know whether it's predestination. I don't know whether it's preordained, but some guys from the very minute they're born—and they can be born in a rotten neighborhood—but from the very minute they're born, they are preordained or something to Make It. And there are other guys who are born to be Sunk. I mean just born to it. Your ship is leaking. From the very minute you start to walk. Your shoes squeak. And you're phonying it up, and hoking it up from the time you're six. Other guys *win* the sack races. You know, legitimately. They can run faster.

Well, let me tell you what happened one time. I'm on the air, you see. I'm a ham, and this is when I began to discover this principle. I'm a kid, and I got this paper route—rout. It was both a route and a rout. It's terrible to have to admit that even when I was a paperboy, I was a paperboy for a paper that was about to go out of business.

Every week you'd come around and you'd try to collect, and they'd tell you they want to drop the subscription, it's a rotten paper. It's awful. I had a paper called the *Herald-Examiner*. Did you ever hear of it, the *Chicago Herald-Examiner*? And you know it was such a bad paper that they didn't even read it in my house, and we had a free subscription.

"I am calling CQ from 9 o'clock at night till 4 o'clock the next morning. All I am raising is our light bill."

I used to go running around the neighborhood at four o'clock in the morning, delivering this rotten paper. It was a losing battle. And on Saturdays, every morning, I would go up and I'd knock on every third door, trying to collect the dough, and they'd say:

"Here's forty cents for last week. Please don't deliver the paper any more."

Well, then I'd have to go back and tell George The Paper Man that they quit down there, on Cleveland Street, those people down there, and he'd say:

"Ah, they're rotten people."

George was fighting a losing battle, too, because he had the *Herald-Examiner* franchise in the neighborhood and he was going down with the ship. And all these poor little kids who were 12 years old and who were getting knobby knees from running around with this paper, they were going down, too. Whereas right across the street from us there were a bunch of wiseguy kids who had the *Tribune*. And this big fat guy who had the franchise for the *Trib*. And they all got fat. All those kids are Republicans today. And Cub fans. All of the rest of us kids that had the *Herald-Examiner*, look at us. Ha! Democrats, following the White Sox till the day we die.

So anyway, I'm a kid and I get my ticket, and I figure I'm licensed, like all the rest of the guys. Except, of course, the Cadillac has the same kind of license on it that you've got, you know. It's the same piece of metal on the back, but Boy, what a difference.

So I get my ticket. I'm really gonna swing. I'm on 40 CW for about six or eight months, when I get on phone. Now I'll tell you what I was doing as far as phone is concerned. I figure I'm gonna try and make it in the big leagues. And I have a single 2A5. Final driven by a 56 tri-tet osc. Do you know anything about the 2A5? Well, it was a Pentode, a Power Pentode. Receiving type. I got ahold of this 2A5, and I was using a Majestic B Eliminator, which I had found in the basement of somebody's house, to power this thing. And it put out 135 volts. I can tell you exactly what I was running, it was 135 volts on the plate at 10 mils. So you can figure out what my input was. Into an RCA mismatched

receiving doublet SWL antenna. A special design they had to mismatch on everything. Didn't match anything. I could have done better with the bedsprings.

And so I've got this thing tuned up, and I'm running a cool 135 volts at 10 mils on the plate. I built a modulator. Oh, when I think of it. . .how sad.

The modulator was another 2A5, and I am grid-modulating the final. Well, you can realize the kind of output I have. I'm probably running about 7/10ths of a Watt, and you will never guess what band I'm running it on. I'm on 160 meters. Where a low-power guy was running 200 Watts and the high-power guys ran all the way up to, well, I would say WNBC standards.

I had this poor little receiver. I don't know whether you ever heard 160 meters when it really was wild. You know what you could do on 160? You could tune into the band, and when you hit the band it was one heterodyne from one end to the other. One *solid* heterodyne, without a break. And the heterodyne was of such a magnitude that your S-meter was on the pin all the way across the band. It never fell off.

So one night I'm on there. I throw my 7/10ths of a Watt right into the middle of it all. I have a very vocal special sound, the bored sound of a high-power man, calling CQ. Nonchalantly:

"Hello CQ, CQ 160. Hello CQ, hello CQ, hello CQ." Then there's a little silence while I'm tuning. [Sound of arc being drawn by pencil from final plate.]

"Hello. One Two Three. . .hello. Hello CQ, hello CQ, hello CQ."

Where you really sound like a big leaguer is when you turn the radio in the next room all the way up, so you sound like you've got so much power and so much gain, so much preamp gain that you can't cut down the background noise in your house. It sounds real great.

I've got the cans on. I'm wearing cans monitoring myself on my receiver. I am the only guy who can hear me, the only guy who could hear my signal.

"Hello CQ, hello CQ, hello CQ, hello CQ."

It's 9 o'clock at night, and everybody in the country is on. Believe me, that band was so insane and my rig so weak that with my signal on and my receiver on, I could hear the heterodynes through my carrier. If you know what I mean.

"Hello CQ, hello CQ, hello CQ, hello CQ 160, hello CQ."

I am calling CQ from 9 o'clock at night till 4 o'clock the next morning. All I am raising is our light bill. That's all that's happening. So the next night I come on again. I get on the air again, and it's great, you know, just to throw on all the switches. The one thing I had that was heartwarming was that my BH tube was leaky. I had a gassy BH. Did you ever hear of the BH cold-cathode rectifier? Well, it was leaky. It was gassy; it made a beautiful blue light like an 866 when I talked. Made me feel like I had real power.

"Hello CQ, hello CQ, hello CQ, hello CQ, hello CQ." And I'd see that blue light flickering. It was just great.

"Hello CQ, hello CQ, hello CQ, hello CQ."

Well, this goes on for one solid week. They can't even hear me in the next room. I haven't raised even a BCL.

"Hello CQ, hello CQ, hello CQ."

Finally Friday night comes along. And my friend Chuck down the street is W9AHS. He is running 6/10ths of a Watt on 20. He has not worked anybody on 20 since the preceding spring, when he worked a guy who was mobile and who drove right past his house. So the two of us are in the same leaky rowboat.

Chuck comes home from school, and he says:

"You're on 160, huh? How're you doing?" And I say:

"Ah, pretty good, Chuck. How are you doing on 20?" Twenty is a real Big League band. He says:

"Oh, not bad. Not bad."

We both made Class A, you see, but I didn't have the guts to go on 20 yet, because the band scared me.

Chuck says, "What do you say we work a little crossband tonight?" Chuck lived 10 blocks away from me. So I say:

"Okay, Chuck."

So Chuck has got his receiver tuned to 160 and I'm listening on 20 and sure enough, between all the heterodynes I hear Chuck come in:

"Hello, hello W9QWN, hello W9QWN, W9QWN. W9AHS calling W9QWN." So I throw on my transmitter. I'm on 160:

"Hello W9AHS, W9AHS." And Chuck comes back to me! Fantastic! He could hear me. Right in between all the heterodynes he says he could hear this little squeak, this little thing. He says:

"You're coming in. You're about an S2. About an S2. Readability is very low. About an R3, I'd say, about every 3rd or 4th syllable."

So, without thinking about it, we slip into crossband work, into duplex. And I leave my transmitter on, Chuck leaves his on, and I'm talking to Chuck. We worked crossband, *duplex*, for not more than 30 seconds.

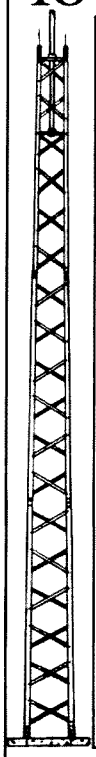
Illegal.

And I'm talking to Chuck, Chuck's talking to me, back and forth. It was great. Finally:

"73, Chuck."

"Okay, Dad."

"Hello CQ, hello CQ, hello CQ, 160 phone—hello CQ, hello CQ."



Six or eight weeks go by. When suddenly, in the mail, would you believe it? I get a card from the FCC. They got a listening station in San Diego. And they have ticketed me for crossband illegal operation. I am coming in there 599 XXXX. A ton of bricks! On 160!

Well, I figured, you know, there's some guys get ticketed and then there's others that don't. About that time I realized that there are born losers and there are born winners.

Oh well, it doesn't matter. It only gets worse. But the thing you got to keep saying to yourself is that it gets worse for everybody, simultaneously, all of the time. Maybe. ■

"When You Buy, Say 73"

TOWER VALUES

Rugged TRYLON ABC* towers designed and fabricated in Canada to survive the severe northern climate, now available in the USA at REASONABLE PRICES ranging from $330 to $2500 and heights between 32 and 160 feet.

EASY ASSEMBLY: Lightweight 8-foot triangular sections in a modular tapering design.

MADE TO LAST: High tensile strength steel and quality zinc coating (ASTM A-526 specification). Painting available. Zinc-plated steel bolts. Virtually maintenance free.

Guyed and free-standing versions available; shipped Factory Direct and guaranteed ONE FULL YEAR after installation.

Write or call BJX SUPPLY CO. for full information and price sheet.

For *Dealer Information* write TRYLON MANUFACTURING COMPANY, LTD. 21 Howard Avenue, Elmira, Ontario CANADA N3B 2C9

Simplex Repeaters?

What are they? And why would you want to use one?

CES, Inc., and local radio amateurs in Winter Park, Florida, have been testing and evaluating a simplified version of the simplex equipment discussed in this article. The purpose of this article is to generate more discussion and ideas on this subject, and not to set down any absolute standard or definition for such a machine.

With the advent of low-cost digital storage for voice retransmission, a new product to serve special amateur needs has become feasible—the Digital Simplex Repeater. The concept is very simple: A base station serves as the repeater, monitoring a standard simplex frequency and storing the received audio transmissions. Whenever a transmission ends, the receiver's carrier-operated relay (COR) signal goes off and the station transmitter will send out the previously recorded message. In its most basic form, the repeater automatically retransmits every received message. While obviously not a great way to carry on rapid-fire rag-chews and nets, this is a simple way for a base station to greatly increase the range of any hand-held or mobile radio unit. By using only simplex operation, all of the costs and technical drawbacks of full-duplex operation are eliminated. There is no input desensitization and no extra signal losses due to a duplexer.

Adding one slight refinement to the system makes it more than just a calling and testing machine: Reset On New COR. What this feature does is reset the digital store-and-retransmit logic whenever a second transmission is detected within two seconds of the first. This allows two stations to carry on direct communication without the delay or interference of the repeater. However, between buildings or in some other "dead zone" the operator needs only to delay two seconds, and the lost or garbled direct message is repeated loud and clear. The first station knows immediately when it is reaching the limits of direct communication when it hears the retransmission. The two stations now have the option of continuing with the repeater's help, signing, or coordinating a switch to an available duplex machine.

When no direct-path signals can be heard between two stations using the repeater, care must be taken to alternate turns using the machine so that doubling—or worse yet, both stations pausing for the other—does not occur. Since this is a valid and very useful mode, it makes sense to limit the storage time to a short period to minimize the "is he replying?" time. Fifteen seconds seems to be the maximum wait tolerance for "A-Type" (impatient) personalities. Fifteen seconds is actually quite a bit of time to relay information and ideas. The repeater, therefore, will only repeat the first 15 seconds of the last transmission. This may seem harsh to those who find two- or three-minute timeouts too fast on duplex machines, but it can be adjusted; it may even improve your operating habits. For a calling-frequency machine, 15 seconds is ideal.

Another possible feature of a simplex repeater is frequency sharing. This is possible when another refinement is added to the controller: Access Code Enable. Assume that the repeater can be activated by a single DTMF tone, such as "1." The tone should be required for two seconds to activate the repeater. This prevents voice "falsing" from inadvertently activating the repeater. Since for most applications the range of the repeater should not greatly exceed the range of the hand-helds or mobiles calling into it, most simplex repeaters should be modest—20 Watts to a 5/8-wave vertical, *not* a kW to a 200-foot-high yagi.

This modest (cellular-like) operation means that several simplex repeaters could be located on the same channel within overlapping areas, giving continuous coverage

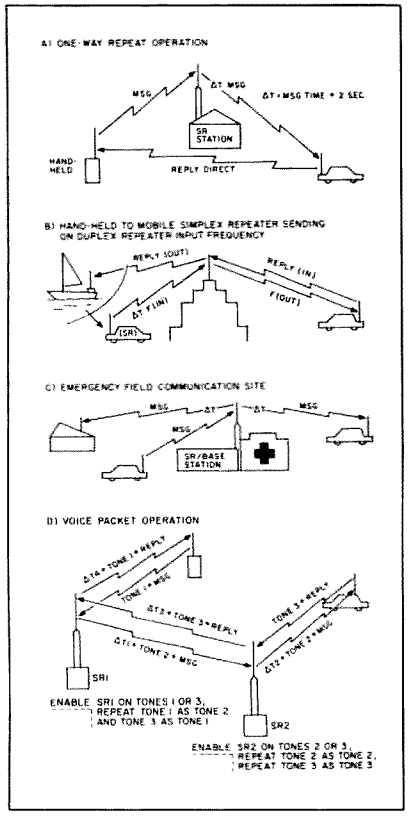

Fig. 1. Simplex repeater configurations.

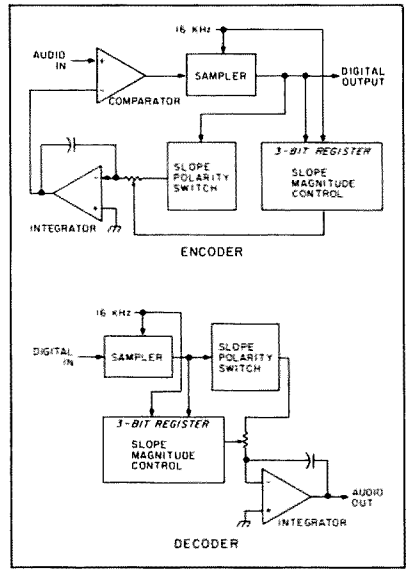

Fig. 2. CVSD encoder and decoder.

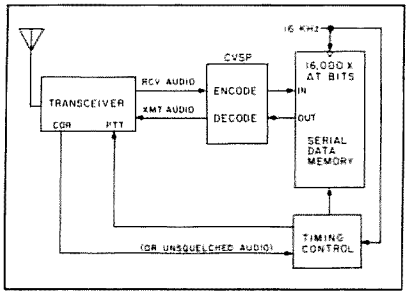

Fig. 3. Simplified block diagram for the simplex repeater.

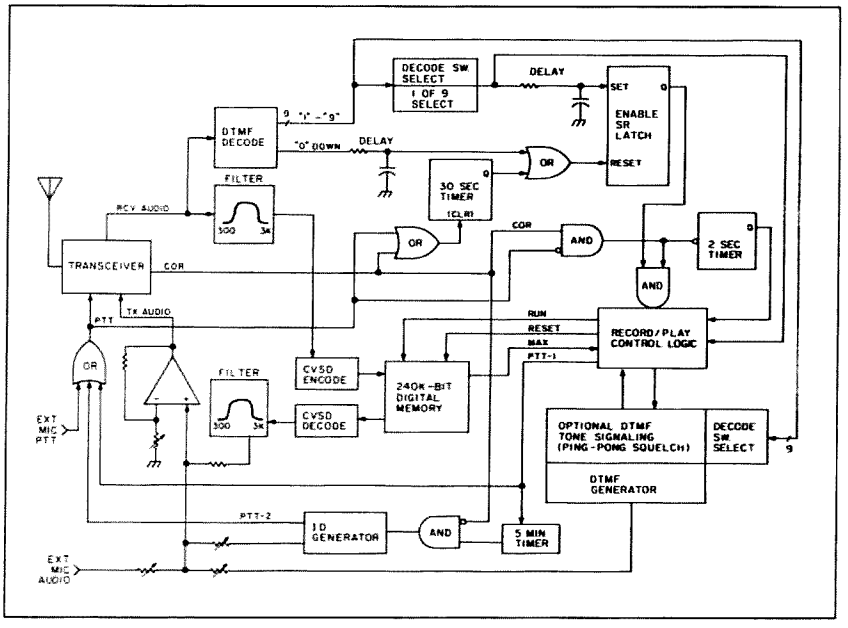

Fig. 4. Detailed block diagram for the simplex repeater.

throughout a major metropolitan area. If "1" and "2" are assigned to repeaters on the north end of the area, "3" and "4" to the east side of town, "5" and "6" to the south end, and "7" and "8" to the west, visitors would know which access code to try, depending on which part of town they were in. Multi-digit access codes could start with "9" and would be used for additional open, or private, repeaters. "0" would deactivate all repeaters within receiving range. With good planning and coordination, more than one repeater should be able to operate simultaneously without interfering with communications going through others.

The fact that one activation code automatically deactivates other machines within the listening range facilitates changing over to the best machine for your area of town. So, if you were using repeater 1 and then sent 2 at the beginning of the next transmission, repeater 1 would no longer repeat your message but repeater 2 would, if in range. This prevents two machines from repeating each other. This ping-pong mode would have occurred if machine 2 recognized its activation code and machine 1 were out of range by the time the changeover code was sent. If machine 2 sent a 0 tone burst as part of its initial ID message, machine 1 would still be deactivated and no ping-pong would occur. Having 0 as a universal deactivation code could be abused by pranksters, but it really is essential when skip conditions develop. Even the multi-digit activation stations should use 0 for deactivation.

As with any repeater, the ID should be automatically transmitted every five minutes (when in service) and must be readable through the repeated transmission. The operator should still identify at the beginning, end, and every ten minutes of the contact or test.

One very popular use of the repeater is for signal checks. It is easier to believe there is a problem if you can hear it yourself. Many DTMF decoder problems are really over- or under-deviation problems which can be readily fixed by just hearing your signal. Also, the simplex repeater is probably a more acceptable way to test for skip conditions—rather than tying up the local duplex machine (and two frequencies) just for a kerchunk and an ID.

Initial inquiries to the FCC indicate that no special authorization is required for the operation described. On 2 meters, repeaters and simplex are permitted between 146 and 148 MHz. So 146.40–146.58 and 147.42–147.57 (except for 146.52) are open for simplex repeaters (30-kHz splits are most common).

Another possible use of the simplex repeater is in your car, while you're out on a boat fishing (Fig. 1(b)). With a hand-held in the boat, you can hear your local repeater. However, without the repeater in the car, the hand-held is probably out of transmit range. If the hand-held starts making it on its own, a quick 0 takes the car "range extender" out of action. Note that the hand-held is in split mode, and the simplex repeater is set to the duplex repeater's input frequency.

For Field Day and for emergency field locations, the simplex repeater becomes a practical temporary-site repeater (Fig. 1(c)). The simplex repeater, whether temporary or part of a coordinated fixed system, could become a useful adjunct to amateur radio from 10 meters on down.

Simplex repeaters mean less congestion on the standard full-duplex channels and more effective direct simplex communications. With only a little imagination, you could set them up to relay messages in very much the same manner as packet radio does (Fig. 1(d)). Multi-digit DTMF tone enabling would most likely be used to signify the repeat paths for forwarding. You should probably consult the FCC before fully exploring this possibility.

The Circuit

The heart of the simplex repeater is the voice-to-digital (encoder) and digital-to-voice (decoder) converter circuit. The simplest way to digitize a voice is to store a digital image of the change of the voice signal, rather than store the digital value of the voice amplitude itself. The name for this type of converter is a Continuously Variable Slope Delta (CVSD) modulator/demodulator. This entire encoder/decoder function is available as a single 16-pin IC which operates on +12 V dc. Since only the change information is stored, the amount of memory required is less than that required by older analog-to-digital conversion techniques.

As with any sampled signal, the sample rate (bit rate) should be at least twice the rate of the highest frequency to be reproduced—this is called the Nyquist rate. The Nyquist rate implies that an 8-kHz sample rate should be sufficient for male voices in the 300–3000-Hz range. The ability of the CVSD encoder/decoder to handle amplitude variations (dynamic range) is enhanced by using higher sampling rates, making a sample rate in the order of 16 kHz more desirable than the minimal rate of 6 to 8 kHz. The total digital memory required for storage is simply the amount of timer storage time multiplied by the sample rate. Therefore, one 64K DRAM would store about four seconds of CVSD voice information, assuming a 16-kHz sample rate.

Fig. 2 shows a simplified diagram of the CVSD encoder and decoder. The encoder samples the difference between the voice signal input and the internal integrator which is being driven by the digital output to track the input signal. Each sampled output from the comparator drives the reference integrator either up or down in magnitude. This "louder/softer" bit is generated every 62.5 microseconds and is stored as one continuous bit stream.

A trick is employed by the CVSD manufacturers to allow an even wider dynamic range than that afforded by the 16-kHz sample rate. Motorola prefers to call this trick a "companding algorithm." The encoder and the decoder use the same algorithm so that the analog (voice) output is equivalent to the

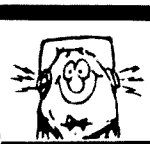
The experimental system works on 146.4 MHz, using 17 Watts to a vertically polarized gain antenna at approximately 100 feet. The repeater operates under station call WA4HHZ. Here are a few of the comments from on-the-air users:

- Hilory K3VMG: "I get a lot of calls on the hand-held I can't answer direct. With the simplex repeater, I can answer back without running over to the main rig."
- Bob N4NDW: "The vehicular simplex repeater will be great for me as an outdoorsman. The possibilities are tremendous."
- Dave K7AFK: "Every club should have one as an on-the-air test machine."
- Jack WD4AWV: "It works fine, but what do you do with it?"
- Andy K4YKZ: "I like the built-in blooper reset feature—just release push-to-talk and start again."
- Al N4BUS: "I would much rather carry a hand-held than a radio in the car. Now my hand-held has the range of my home station."

original input. Companding consists of loading the last three bits from the encoder into a 3-bit shift register and digital comparator. If all three bits in the register are 1's, the reference integrator's output will be set to ramp up faster; if all three bits are 0's, the output will be set to decrease faster than if the two previous bits were not 0's. This simple fudge control over the integrator's gain increases the ability of the CVSD to respond to rapid changes in amplitude without increasing the overall memory requirements.

Fig. 3 shows a simplified block diagram of the simplex repeater. The only signals needed to control the system are COR from the radio and PTT to the radio. COR is the internal radio signal that disables the radio's squelch. Some transceivers provide this signal to a connector output, but the signal must be found from the schematic on most amateur radios. A few radios do not have a signal that is suitable for use by the repeater. For these radios, COR must be generated by an additional circuit that senses background noise on the unsquelched audio signal.

The receive signals to the repeater's CVSD decoder can be speaker audio or unsquelched audio. If the speaker audio is used, the volume setting cannot be changed once it is adjusted for the proper output deviation level for transmission. So, if the repeater is also to be used as a base control station, the audio to the repeater should come from the audio circuitry that precedes the volume control.



The PTT signal to the transmitter is activated to the radio two seconds after the COR goes off and remains off. The timing control must also ignore false COR inputs that normally occur immediately after PTT is released.

Fig. 4 shows a more detailed block diagram for a system that includes more bells and whistles. In addition to the basics shown in Fig. 3, the following seven functions are shown: (1) DTMF decoder for repeater activation/deactivation, (2) analog pre-filter and post-filter for CVSD, (3) auxiliary microphone input with gain control, (4) 2-second "wait for COR" timer, (5) 30-second deactivation timer, (6) 5-minute timer and ID generator, and (7) optional ping-pong squelch generator.

With the cost and complexity of the digital encoder/decoder and with memory no longer a major factor, the success of the simplex repeater depends on two important factors:

- Acceptance of the concept and constraints by the amateur community
- Technical improvements resulting in more sophisticated operation and reduced costs

Other factors that will weigh heavily on the spread of the simplex repeater are the FCC and ARRL. The "voice packet" concept is bound to be tried using simplex repeaters. This operation most likely will require regulatory sanction before it can grow. The basic one-repeater system, however, should be well within the limits of the current regulations. The challenge today is to try it, then improve it, and—some day—standardize it. ■

Messing With Microwaves

Build a simple microwave transmitter and receiver for just pennies a MHz.

One area of electronics that seems to be sadly neglected by amateurs is microwave communication. This is due to the high cost of microwave components and the difficulties associated with microwave circuit construction. If this is what's holding you back from experimenting in this fascinating field, I think you'll enjoy this article on the construction of a simple microwave transmitter and receiver.

The transmitter and receiver described here are of such simple design that it is possible to build both in only a few hours and at a cost of less than $30. And since the design doesn't use exotic parts, you should be able to get all the components necessary to build both the receiver and the transmitter at Radio Shack.

First, let's begin with the transmitter since it's the more difficult of the two. Begin by getting a square piece of single-sided copper-clad PC board about 8 cm in diameter. In the center of this board, drill a hole large enough to accommodate a 1" 6-32 nylon screw. Before inserting this screw, take a small brass tube about 3.2 cm long and about 3 mm in diameter and solder it to the PC board—centering it just below the center hole (see Photo A). A good source for the brass tubing is a ball-point pen that uses the old brass ink cartridges. Once the brass tubing has been soldered to the PC board, you can insert the 1" 6-32 nylon screw in the center hole. This screw will be used to support the antenna once the components have been laid out on the PC board.

The next step in the construction of the transmitter is to drill another hole, in line with the first, 2 cm below the brass tubing. This hole will help form the variable capacitor which will be used to vary the frequency and power of the transmitter. A thin square piece of copper or brass, measuring ¼ cm along each side, is used to form the top plate of the capacitor. In the center of this small square, drill a hole that matches in size the hole drilled below the brass tube. Place a square piece of mica, somewhat larger than the square piece of brass, between the brass

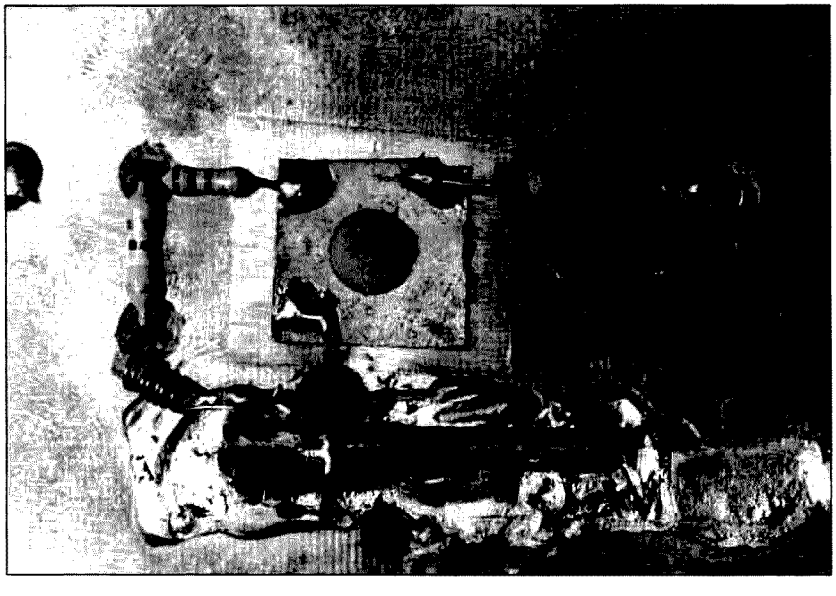

Photo A. The transmitter. The homemade capacitor is in the center, L1 is the long tube at the bottom and L2 is to the left of Q1.

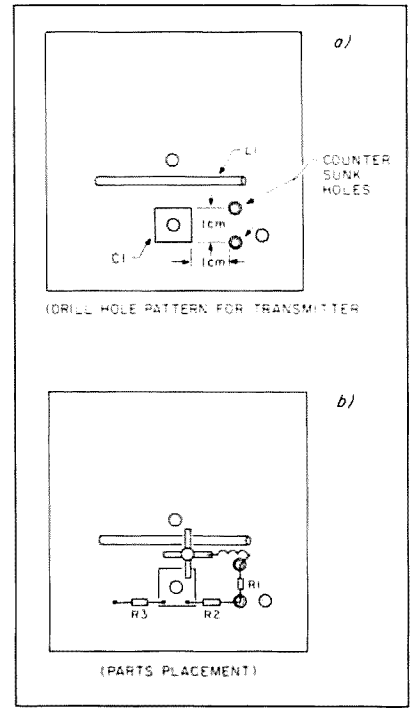

Fig. 1. (a) Drilling pattern for the transmitter board. (b) Parts placement.

square and the PC board. Transistor mounting kits sold in electronic supply houses are one source for the mica. A nylon screw is then inserted through the brass square, the mica, and the PC board. Complete the construction of the capacitor by attaching a nut to the screw on the back side of the board. By tightening or loosening the nut you'll be able to vary the capacitance on the homemade capacitor, and thus tune the transmitting frequency and vary the power.

After completing the variable capacitor, we must drill three more holes into the PC board to mount the four remaining parts. As you can see from Fig. 1, these holes are in line with two of the four edges of the variable capacitor. Two of these holes, 1 cm from the edge of the capacitor, must be drilled in a special way. Start by drilling two 1/32" holes 1 cm to the right of the right-edge corners of the capacitor (see Fig. 1a).

After these two holes are drilled, it will be necessary to countersink them by drilling in the same spot with a larger drill bit. With a ¼" bit, drill from about ¼ to ½ way through the PC board. The countersinking process is necessary for the removal of copper from around the holes, which prevents short-circuiting of the resistors to the ground plane. The third hole can be drilled anywhere along the bottom of the PC board, preferably close to the 1k-Ohm resistor.

Once the holes are drilled, the resistors are inserted as shown in Fig. 1b. On the right-hand lower corner of the capacitor, one lead of a 1k-Ohm resistor is soldered. The other end of the resistor is inserted through the hole immediately to the right. Directly to the left of this resistor (the lower-left corner of capacitor) a 4.7k-Ohm resistor is soldered to the top capacitor plate, with the other lead soldered to the PC board.

The final component, a 47-Ohm resistor, is installed in the two holes drilled that run parallel to the right hand side of the capacitor. After the leads of the resistor are inserted, you may at this time turn the board over and solder the leads of the 47- and 1k-Ohm resistors together. The other end of the 47-Ohm resistor is connected to a small inductor of your own making. It is formed by wrapping five turns of 30-gauge wire around a match stick. Once the wrapping is finished, slide it off the match and attach one end to the 47-Ohm resistor. The remaining end of the inductor is soldered to the emitter of the MRF 901 transistor (see Photo A). The base lead of the transistor is attached to the top plate of the capacitor, and the collector is attached to inductor L1 (the 3-cm-long tube).

The last bit of work involves soldering the power leads to the transmitter and installing an antenna. First, insert a red wire through the third hole, which we have not used as of yet, and solder it to the front of the PC board. Then take a black wire and solder it to the junction of the 47- and 1k-Ohm resistors.

This just about finishes the construction of the transmitter except for the antenna. The antenna is made by taking a thin strip of metal

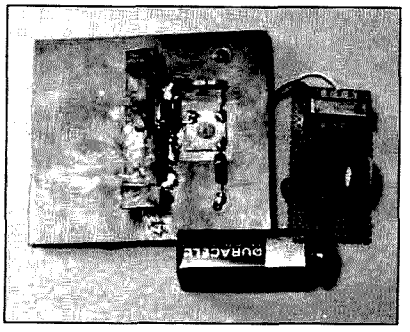

Photo B. With a power source, a modulator, and an antenna, the transmitter is ready to tune.

about 1 cm in diameter and 6 cm in length. At its center drill a hole to fit the nylon screw that formed the antenna mount described earlier. The height of the antenna should be adjusted (by the use of nuts) to a height of 1 cm above the ground plane for maximum signal transmission. For the antenna to function properly, it shouldn't touch any metal—such as the ground plane or inductor L1 (see Photo B). You may ask, how does the antenna work if it doesn't make contact with anything? It turns out that the microwave signal is transferred to the antenna by the inductive coupling with L1.

At this point our transmitter is fully functional and could be operated simply by applying power to it. However, I have found that many times it's more desirable to have the

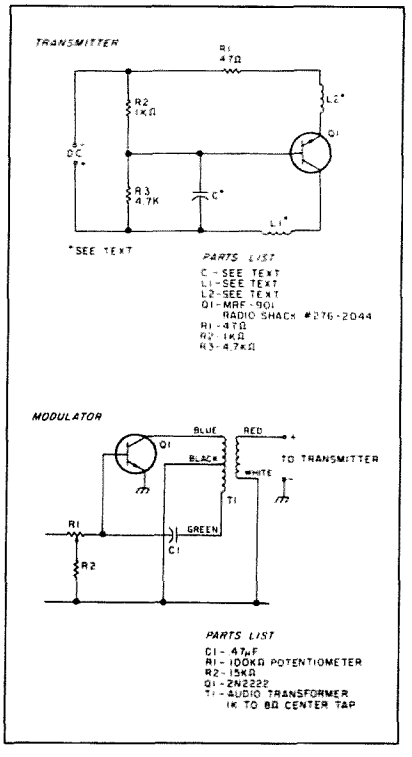

Fig. 2. Schematic diagram of the microwave transmitter and its companion modulator.

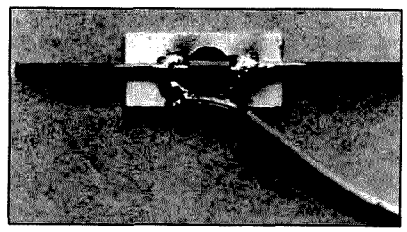

Photo C. The microwave receiver is a simple crystal detector.

transmitter modulated by the circuit shown in Fig. 2. This circuit is basically an oscillator that uses one side of an audio transformer as an inductor to provide the necessary feedback for oscillation to occur. To control the frequency of the oscillator you need only vary the resistance of potentiometer R2.

The Receiver

Once the modulator is constructed, the transmitter section of the project is finished. Now you are left with only the construction of the receiver. The receiver isn't far from the type built by most electronics enthusiasts at one time or another. It's the basic crystal radio receiver! The major difference is the length of the antenna and the type of diode used to detect the signal.

Start by finding the wavelength of the transmitter by using the following formula: $\lambda = v/f$, where f is the frequency in MHz, v is

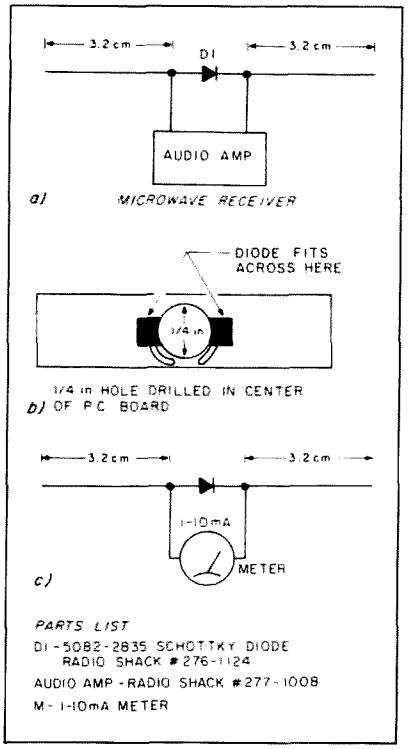

Fig. 3. (a) Schematic diagram of the microwave receiver. (b) Optional receiver PC board. (c) Using the receiver as a field-strength meter.

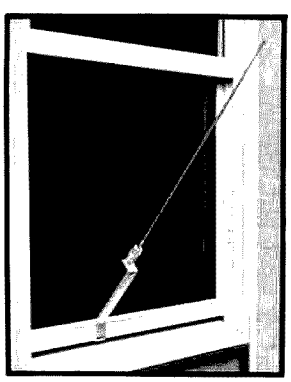
the speed of light in km/sec (300), and λ is the wavelength in meters. Using these values we find λ = 300/2400 = 0.125, or about 13 cm. For a dipole antenna, each leg should be ¼ of a wavelength long. So divide your answer by 4, giving you a value of 3.25 cm for each leg of the dipole. In truth, the antenna should be slightly shorter than this value due to end effects. However, since the transmitter can vary several MHz above and below the stated frequency of 2.4 GHz, this makes a good first guess.

To detect the signal generated by your microwave source, you must choose a diode capable of operating in the microwave spectrum. The diode that I use is the 5082 Schottky diode, available at most Radio Shack stores at relatively low cost. Other diodes designed for microwave use should work equally well, but as of this writing the only other diode I have tested is the 1N82A. This diode worked well, but it may be more difficult to obtain than the 5082. As can be seen from Fig. 3a and Photo C, construction of the receiver is trivial. Two stiff pieces of wire measuring 3.25 cm in length are attached to the ends of the diode to form the dipole antenna. A short piece of shielded cable is then connected across the diode, leading to an audio amplifier. In Fig. 3b, a PC board is shown for the receiver, if you wish to use it.

In Fig. 3c, the receiver is shown connected to a 1-mA meter for the purpose of peaking the transmitter output. This is done by first applying power to the transmitter and then placing the receiver at such a distance that the meter reads about half scale. The capacitor on the transmitter is then adjusted until the meter shows that maximum power is being transmitted. To truly maximize the power of the transmitter, it may be necessary to trim or lengthen the antenna, but in general the lengths given will work just fine.

Applications/Experiments



The first experiment is to measure the wavelength of the transmitter by a method called interferometry. Here we place the transmitter and receiver side by side, separated by a flat piece of metal to reduce interference with each other. A second piece of metal, somewhat larger, is placed a couple of meters away in front of the transmitter-receiver pair. This is done to cause the formation of a standing wave between the second reflector and the transmitter-receiver pair. To measure the wavelength of the transmitter a small third plate is inserted between plate number 2 and the transmitter-receiver pair. This third plate is then moved back and forth in between plate 2 and the transmitter-receiver. As this is done, a series of high and low tones will rush forth from the receiver. These tones, caused by constructive and destructive interference, will correspond to the nodes and antinodes of the standing wave. By simply measuring the distance that the plate is moved from one low tone to another, we can get a good estimate of the wavelength.

One possible use of the microwave transmitter-receiver came to me when I was performing the preceding experiment. As I was setting up the experiment, I noticed that as I walked around the room the same high/low tones were generated. It seems that standing waves are generated in the room as they bounce off the wall. As I walked around the room, some of the microwaves were bouncing off of me and causing the constructive/destructive interference needed to produce the high/low tones. But these tones were generated only when I walked about the room! So one possible use for the transmitter-receiver is for a very crude motion detector.

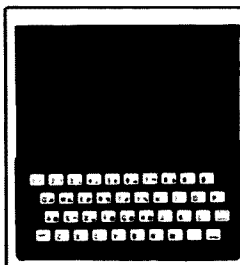
Another possible use is to construct a small radar system to measure the speed that objects are moving away from or toward you! Then, of course, there is always microwave communication to keep you busy. At this point, it's up to you to experiment and find uses for it.

One final word: The transmitter described here is one of low power output. However, its output *is* above the leakage level considered safe on microwave ovens. *Do not treat this as a toy!* It has great potential as a tool for learning about microwave radiation, but it should be respected at all times. ■

PORTABLE ANTENNA

MODEL AP-10

Designed for
APARTMENTS
MOTELS
VACATIONS



PRICE
$51.95

Add $3.00
Shipping and Handling

Quick Simple Installation. Operates on 2, 6, 10, 15, 20, 30 and 40 meters. All coils supplied. Only 22-1/2 inches long. Weighs less than 2 lbs. Supplied with 10 ft. RG 58 coax and counter poise. Whip extends to 57 inches. Handles up to 300 watts.
VSWR—1.1:1 when tuned

They Threw What Away?

Your tax dollars at work: This time it's a UHF swr bridge.

I want to stress right at the beginning that this is intended to be a fairly serious article, not a sarcastic put-on of the "101 Uses for a Dead... (Transmitter, Computer, Battery, etc.)" variety. My intent is to alert the ham community to a particularly useful piece of military surplus gear and to suggest some innovative applications. Granted, not all of these are strictly limited to amateur radio, but then, most active amateurs have other hobbies as well.

First to the device itself. It's called a "Transmitter Performance Monitor R.F. Failure Alarm," and the model number is LDWS 00685 AD000. It consists of an aluminum rack-mount panel 1-3/4" high mounted to a 9-1/2" x 5-1/2" x 1-1/2" chassis with a cover plate. Inside, there are two small circuit boards; a dc alarm buzzer; three precision crystal-can relays; an assortment of pots, switches, and lamps; and the "Main Goodie" (see Photo A).

The Main Goodie is the reason I became interested in this item and purchased several at a surplus house near a big Air Force base in northern Michigan. It is a very high-quality UHF swr bridge with N series connectors mounted on the back wall of the chassis. The bridge is about 1" square and 4-1/2" long and is conservatively rated at 60 Watts @ 225–400 MHz, though I've used one on 2 meters with no problem (see Fig. 1).

The manufacturer's label identifies the Main Goodie as a Directional Power Indicator, model 3023 made by Coaxial Dynamics, Inc., of Cleveland, Ohio. From talking to one of the alarm manufacturer's employees at a hamfest and from the four-digit serial numbers on the ones I purchased, it's my guess that there are at least several thousand of these floating around out there in the surplus community, so keep your eyes peeled. The dealer from whom I got mine was selling them for the scrap price of the aluminum, about $1.40 a pound!

The original purpose of the device was to measure the carrier output of an Air Force UHF transmitter and to sound the alarm if the output to the antenna array fell below or rose above certain limits, preset by the pots on the front panel. Only the forward current side of the bridge was utilized; the reverse, or reflected, side was not connected. Hooking the bridge up to a 2-Watt Wilson 1402 HT on 2 meters generated about 1.5 mils on the 50-milliamp scale of my VOM for about 1-3/4 Watts of forward power at 146.52 MHz; reverse current as measured on the other terminal was negligible.

"The dealer from whom I got mine was selling them for the scrap price of aluminum, about $1.40 a pound!"

Besides giving a good relative F/R power indication for tuning and matching antennas and the like, another application immediately suggests itself to the ingenious amateur on a budget. Borrow somebody else's high quality precision UHF power meter, such as a Bird. Put it in series with the model 3023, a good resistive dummy load, and your UHF or VHF transmitter. Using either a surplus meter movement or the appropriate scale on your VOM, calibrate the model 3023 for a useful range of forward and reverse power levels. Then when you return the borrowed meter, as you eventually must, you will still have a highly accurate

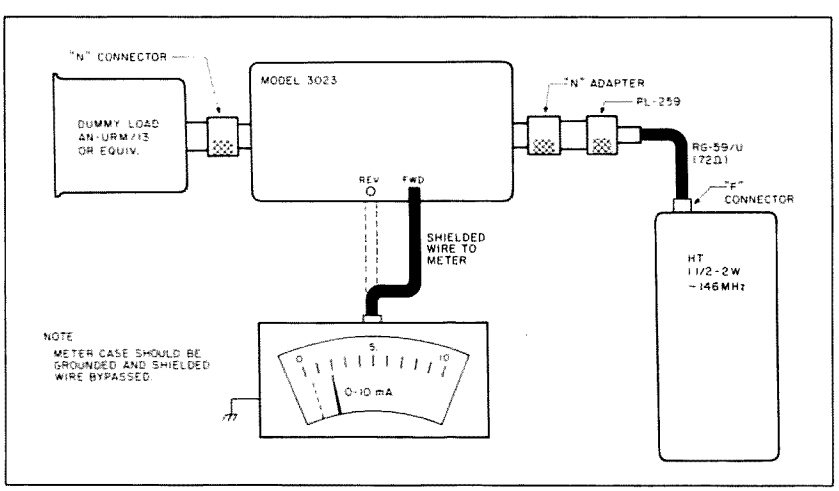

Fig. 1. Low-power 2-meter test setup.

power meter, adequate for most amateur purposes.

I have sold or traded several of these to other hams at hamfest flea markets. Most planned to use them as swr bridges or repeater monitors on 220 MHz. Besides the Main Goodie and its associated expensive silver-plated N connectors, several other parts in the assembly are worth scrounging. There are two very nice illuminated cartridge fuse holders, though you need to change the dropping resistor for the panel lamps if you use the fuse at some voltage other than 28 V dc. As is, the indicators are very dim when used at 12 V dc and *very* bright (but short-lived) at 110 V ac! There is also a matched pair of 2N3819s, common values of 5% resistors, etc.

Once you have salvaged the UHF bridge itself, there is one other small obstacle to be overcome before you put it directly into service. The current from the matched pair of diodes in the bridge is brought out to the alarm itself on a pair of miniature shielded coax connectors. Mating connectors for attaching your metering circuit are usually gold-plated and very expensive if purchased new. However, the same family of connectors is used in a lot of old avionics and other military surplus from the 1960s. I scrounged a few sets from some old Iranian terrain-following radar gear that a surplus dealer was going to melt down for the scrap gold. If you don't just happen to have an F-4 Phantom or similar jet fighter plane in your junk box, try the flea market at one of the big hamfests like Dayton or Orlando.

As a last resort, you can get out a small propane torch or a hefty (200-Watt+) soldering iron and carefully open up the cover of the silver-plated brass cavity of the bridge itself. It's perfectly possible to do this without destroying the diodes if you are careful. Once the plumbing is open, you can replace the connectors with insulated feedthroughs, RCA phono jacks, or some other more practical connectors. While you're at it, you might want to replace the N connectors with SO-239s or BNC fittings, though the N fittings are better. Adapters to UHF or BNC hardware are readily available in most surplus catalogs.

All right. Suppose you've got your hands on one of these and have pried out the UHF bridge for that new 220 FM repeater the local club is going to get on the air one of these days. You've carefully stripped the little circuit boards, and the miniature relays are going into the repeater controller. The 9-1/2" x 5-1/2" chassis will make a nice shielded enclosure for a home-brew direct-conversion or regenerative receiver for some Novice, maybe using the 2N3819s for the front end, if they're still good. That leaves the front panel, a 1-3/4" x 19" strip of 1/8" aluminum with some holes punched in it.

Before throwing the strip of aluminum away, or using it to beat the dog, reflect on the possible constructive applications. With the original chassis and shielded cover attached, the panel is almost a perfect fit for the standard 6-1/2" x 4-1/2" size circuit board with enough room left over in one end of the box for a hefty power supply. This size card is used by a number of different computer, video, and robotics companies and also fits several standard sizes of prototyping and perforated boards. It's hard to imagine a better way to mount a repeater controller, autopatch system, satellite antenna controller, etc. If you find that the 9-1/2" x 5-1/2" box is too small, almost any chassis up to about 17" wide can be installed on the panel utilizing the mounting holes already punched.

Photo A. The Main Goodie.

Even if you already have an excess of rack panel enclosures of all sizes, most amateurs can think of something to do with the panel itself with a little effort and ingenuity. A heavy strip of aluminum almost exactly a quarter wave long on 2 meters lends itself to all sorts of things, from a tuned line filter to a heavy-duty antenna element. Many times, I have been frustrated when I found that I needed a ruler or straightedge that was just a little longer than the standard 1-foot kind, but not so long and clumsy as the yardsticks that lumber yards give away. Scratching or etching metric or English measurements into a strip of aluminum like this takes only a few minutes and yields a very durable and versatile draftsman's aid.

If you have two strips like this, you can bolt them together by putting a countersunk flat-head machine screw through the central hole, the one originally intended for the alarm buzzer. This makes a great adjustable angle gauge for putting framing rafters on the new roof for a hamshack, tool shed, garage, etc. or for setting the angles when building antenna mounts, spiders for quad antennas, etc.

It has been my experience that 1-3/4" strip aluminum like this is very versatile, as it is soft and narrow enough for you to bend with pliers and a vise to make all sorts of brackets, mounting hardware, gamma match capacitors, and so forth. Heating the strip slightly with a propane torch to soften it before bending makes forming complex curved shapes like CRT mounting brackets and cable clamps even easier, though you should be very careful when doing this and take sensible safety precautions. ■

Those Tantalizing Twos

ICOM's 2-meter HTs have a secret! For about a buck your IC-2AT will cover 145–155 MHz. Have an IC-02AT? It's really a 140–163-MHz scanner. And the audio can be boosted . . .

How would you like to have a VHF high-band receiver and a 2-meter handie-talkie all in one? If your answer is yes, do I have good news for you. ICOM makes it easy.

Several years ago I purchased an ICOM 2AT hand-held. Being a curious type, I had the schematic out and the back cover off almost before I got it out of the box (not recommended if you like the convenience of warranty service should anything go wrong). Upon closer examination, I discovered that the 2AT could be made to cover a portion of the 150-MHz spectrum. It's simple, and it's cheap—now *that* should appeal to a few people!

The Procedure

First, remove the battery pack. Then remove the four screws that hold the battery-retaining bracket and set it aside. Remove the two screws that retain the rear cover, and carefully separate the front and rear assemblies from the chassis. Carefully unplug the flex board going to the DTMF unit on the front cover. A small pick or screwdriver will make this easier to reach. Be careful not to break the small wires going to the speaker and the mike! Now remove the two Phillips-head screws on the side of the chassis nearest the PTT switch. The chassis will now open up like a book.

Refer to the schematic and the parts placement diagram in your manual; I have included sections of these in Fig. 1 in case you've lost yours. Notice that there are some unused pads on the circuit board going to pin 15 of the TC9122 PLL divider chip. This is the D1 pin, in ICOM nomenclature. If it is tied high (+5 V), the PLL will tune from 150 to 159.99 MHz. Another pad is ground. What you need to do is put a small bypass capacitor from pin 15 to ground, and a switch from pin 15 to the R5V line (receive +5 V since the object is to receive and not transmit). FCC rules prohibit the use of non-type-accepted gear for transmitting on these new frequencies.

"One of the combinations I hit upon allows the 02AT to initialize at 00.00 MHz and range to about 327 MHz."

Switching

Here's where your creativity comes into play. You may want to mount a switch differently than I did, so feel free to do so. Here's one way: Since I do not use a speaker-mike option with my radio, I borrowed the mike jack position to mount a switch (Photo A). First, disconnect and tape the wires going to the jack. Then remove it from the radio. In its place you can mount a small toggle switch. (You will see what I mean by small when you open the radio and see the cramped quarters!) I found mine at Radio Shack. Connect a small wire (wire-wrap wire will do) from one switch terminal to pin 15 of the PLL chip. Connect the other terminal to the R5V line. See Fig. 1 for details. Use a small, low-wattage iron.

There is one more wiring change if you have one of the earlier 2ATs. To enable all switch positions on the thumbwheel switch,

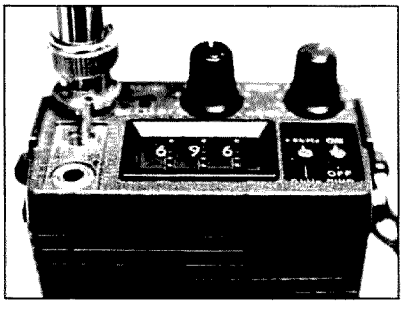

Photo A. Install the range switch in the microphone jack position.

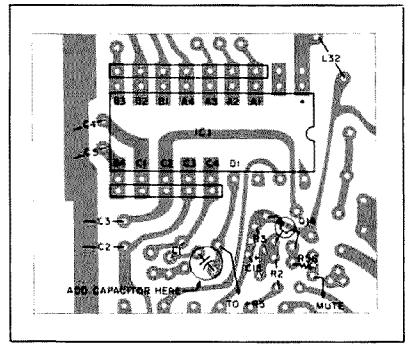

Fig. 1. Pulling pin 15 of the PLL divider chip high will cause the PLL to tune from 150 to 159.99 MHz.

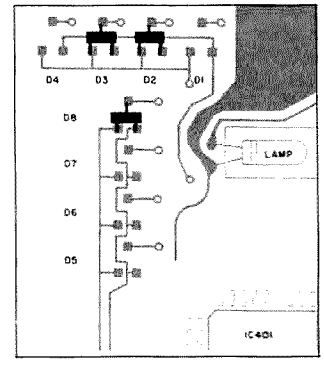

Fig. 2. Remove diodes D2 and D3 from the IC-02AT initialization matrix board.

do this: Find the flexible board running from the PLL divider to the thumbwheel switch. At the switch end, remove the jumper wire (see Photo B), and at the PLL end, bridge the gap in the trace at C4.

With the wiring done, you can close the chassis back up and replace the two Phillips screws. Replace the front cover. Don't forget to plug in the DTMF unit. Now temporarily replace the battery-retaining bracket using two of the four remaining screws. Install the battery pack. Now it's time to tune the PLL free-run frequency so the PLL will track over the new frequency range. Locate L3 in the vco can and, using a soft tuning tool, adjust for a voltage of about 0.75 volts at the lowest frequency desired at the test point. The proper resistor is identified by its lack of paint on the top lead.

The PLL will tune only over a 10-MHz range, so you can see that to get to 155 MHz you have to give up 144 MHz. This is not a problem in southeast Alaska since we have only one or two active frequencies, and all are at 146 MHz or above.

Receive sensitivity will be poor at the high end of the new frequency range but should be adequate for local listening. If you desire more sensitivity and have access to the proper test equipment, you can retune the receiver to favor the higher frequencies.

To use the modified ICOM 2AT, think of the switch as toggling between 140 and 150 MHz. Then just dial in the rest of the frequency as normal.

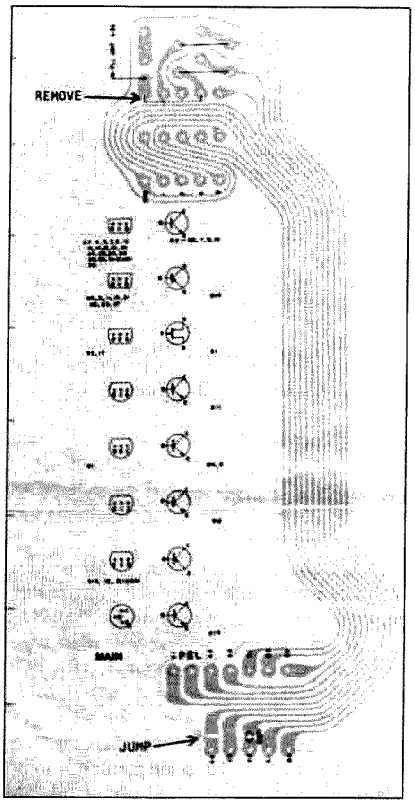

Photo B. If you have an early model of the 2AT, these two changes will enable all of the digits of the thumbwheel switch.

IC-02AT

As you can see, there are some limitations to this modification. After a year of using my modified 2AT I felt it was time to upgrade. Being partial to ICOM, I purchased the new 02AT. With the schematic in hand before the radio, I discovered that the microprocessor had an external initialization diode matrix. Aha, time to see what it would do!

After some experimenting, I discovered that I could make the microprocessor think it was an aircraft-band radio, a two-meter radio, a business-band radio, a 220-MHz radio, a 440-MHz radio, a 450-MHz business radio, a 1.2-GHz radio, and on it went. ICOM had designed a universal software program that would make the same processor work in all current and future products. Now remember, the actual radio is limited by tuned circuits to operation over a specific range of frequencies. Only the processor was being changed, not the radio. (Before you dig into your 02AT, check the serial number: It appears that rigs with numbers higher than 35,000 utilize different software. I'm working on a mod for these radios.)

One of the combinations I hit upon allows the 02AT to initialize at 00.00 MHz (dc) and range to about 327 MHz. In the middle of that range is two meters.

Changes to the initialization matrix cause the following to happen:

1. Direct frequency entry from 144 MHz to 165 MHz.
2. Offsets of up to 20 MHz.

The vco circuit will track over a 20-MHz range, but the bottom 4 MHz is not very linear, causing excessive deviation of the transmitted signal and a 1-kHz tone to appear on the audio. Deviation in the upper 5 MHz or so begins to fall off slowly with an increase in frequency, but that is of no matter since you won't be transmitting up there anyway.

How to Modify Your 02AT

1. Remove the battery pack, back cover, battery plate, and front cover, in that order. The front cover does not come free, but is attached with a ribbon cable to the main chassis.
2. In the front cover, locate the DTMF unit and remove the two screws holding it in place. Bend the metal tab of the matrix shield out of the way; then lay the DTMF unit over to the side.
3. Take out the three screws holding the matrix shield and remove it. These screws are tiny; don't lose them!
4. Using solder wick and a small flat-bladed soldering iron, remove diodes D2 and D3 (Fig. 2). Use an iron with a gounded tip since this circuitry is CMOS. Save the diode labeled with a "D."
5. Add three silicon diodes, 1N914, 1N4148, or equivalent, as shown in Fig. 3.
6. Solder the "D" diode you saved to the D5 position (Fig. 3) as shown in Fig. 1.
7. Replace the shield, taking care to look for solder bridges or short circuits.

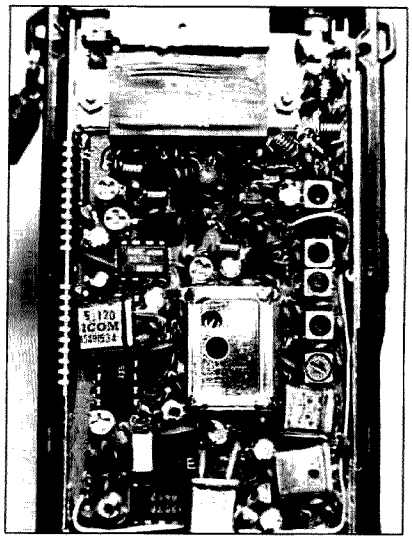

Photo C. L218, the vco frequency control, is located in the large silver box; the coil is under the lower hole.

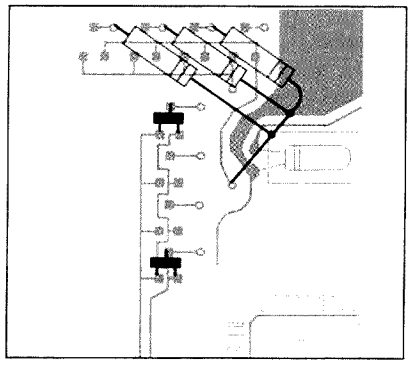

Fig. 3. Diode placement for steps 4–6.

8. Replace the DTMF unit.
9. Replace the front cover, the battery plate, and the battery pack. Leave the back cover off for now.
10. Turn on the radio and enter 140.00 MHz. Attach a dummy load to the BNC antenna jack. This is important as you will be testing out of the ham bands.
11. Key the transmitter using high power and adjust the vco free-run frequency so the display begins to flash. Adjust L218 (see Photo C). Usually the slug will have to be turned out of the can. Unkey and key the transmitter several times to refine the adjustment.
12. Enter 162.80 MHz and key the transmitter. The display should not blink (if it does it's not phase-locked).
13. Replace the back cover when you are satisfied with the range. If you wish to favor a different portion of the spectrum, just pick a frequency 4 MHz below the lowest frequency you normally will want to use and set the lower limit there. Total vco lock range is about 20 MHz on a typical 02AT. But remember that the bottom 4 MHz is nonlinear and not really suitable if you want a clean signal. If you are tempted to tune for a higher

range, and then expect to use the bottom end, beware the wrath of fellow hams, as you will over-deviate and splatter.

Receive sensitivity will be adequate above 155 MHz for local listening, but if you have access to a service monitor, this can be improved to better than 0.5 microvolts for 10-dB Sinad from 144 MHz to 161 MHz, and typically, 0.25 microvolts can be obtained over this range. I measured 0.15 uV for tight squelch at 145.00 MHz, and 0.60 uV for tight squelch at 162.00 MHz. I also noticed that transmit power was at the rated 5 Watts over this same range. This is, of course, only academic since you can legally transmit only in the ham bands with this radio, anyway.

More Audio

Now for a simple audio modification that will give an approximate 6-dB boost to the speaker volume. A quick check of the schematic will show that there is a 0.22-uF capacitor across the audio right after the detector. It is C117. While you have the front off the radio for the other mods, just snip this capacitor out of the circuit. See Photo D for the location.

Operation

There are a few things you will need to know about your radio after you make these modifications:

1. If you reset the processor by holding the function switch in while turning on the power, the display will initialize at 0.00. That's right, zero Hertz. To get up to the 100-MHz range, enter 9999; the display will show 99.99. Then use the up arrow to step to 100.000 MHz. Now you can enter the frequencies you desire.

2. You must now enter the 4 for tens of MHz, as well as the rest of the digits. Only the 1 (for 100 MHz) remains in the display.

3. When entering offsets, you must now enter all the digits. For example, for 600 kHz, enter 00.60. Offsets up to 20.00 MHz may be entered.

4. Any frequency from 140 MHz to 163 MHz may be entered into the memories to be scanned.

5. When entering a frequency outside of the ham bands, it is best to also enter an offset so that if you accidentally transmit, the frequency will fall in the ham bands.

There you have it. At least a dozen hams in this area have made these modifications to their ICOM 02ATs and all praise the mods and wonder how they did without. ■

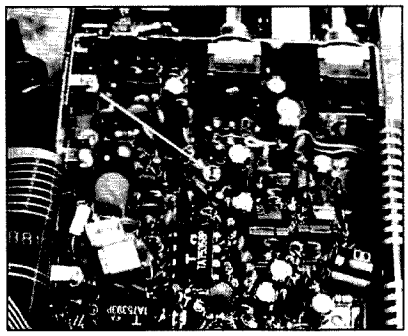

Photo D. Snipping C117 (see arrow) will boost the audio sent to the speaker.

Photo E. The fruit of your labor—an 02AT receiving weather broadcasts on 162.55 MHz.

PACKET RADIO GOES PORTABLE

GLB ELECTRONICS
presents

Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight.
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement: 9 to 15 Volts DC @ 25 mA typical
Dimensions: 4.6 X 5.90 X 1.0 inches
Total Weight: 12 ozs.

PK1L—Wired and Tested
List— $239.95
Amateur net— $209.95

Turn Your Computer Into A
DIGITAL
STORAGE
OSCILLOSCOPE
And More With The
MB230 WORKSHOP

OSCILLOSCOPE

INTERFACE UNIT

The MB230 is designed for use with your home or personal computer. It is a complete Electronic Instrument and Electro-Mechanical Workshop which contains Interface Unit, D.C. Motors, Gears, Sensors, Construction Components, Disk Based Software and instructions for 50 sample projects.

Included are:
- Digital Storage Oscilloscope
- Digital Voltmeter
- Digital Speech & Sound (Record/Playback)
- A/D-D/A Conversion
- D.C. Motor Control (Var. Speed)
- Infrared Control
- Motors, Gears, Generators
- Motorized Mechanical Robotics
- Cars, Cranes, Toys, Etc.

VOLTMETER

MOTOR AND GEARS

The heart of the MB230 Workshop is the B100 Interface Unit which connects to all types of sensors and is able to control lights, motors, relays and other external devices. The MB230 manual contains suggestions and instructions for many advanced projects such as antenna positioning and relay control.

Available for the following computers:
Commodore 64 ($129.95), Apple 2+, 2E ($159.95),
Atari 800 ($139.95).
Coming soon for IBM, Amiga, Atari 520ST.

Computer Rotor Control

The first step toward automating your shack.

Over the past few years, I have had the pleasure of spending many hours in the shack of a close friend who is a seasoned DXer. Watching him operate is always interesting, especially when an unusual call shows up on the band. Within the first minute after hearing the station, he has checked the log to see if he needs the contact, turned the antenna, and quite often established contact. Over the summer, he added a personal computer to the shack to help out with beam headings and the log. Not long thereafter, we got to discussing how great it would be if he could just type the DX station's call on the keyboard and have the computer rotate the antenna to the correct heading and display pertinent logging information. An interface between the computer and rotor control box was what we needed. An interface like this would also make satellite tracking easier and be a major step toward total computer control of the shack.

The rotor control board, tucked neatly inside, awaiting its next command.

I have constructed an interface which will allow any personal computer with a serial port to talk to the control box of a CDE antenna rotor, such as the CD-45, Ham IV, or Tailtwister. The computer need only output a single character representing the beam heading desired. The interface will then close the rotation contacts of the control box, bringing the rotor to the desired direction. The control box requires no modification, functions normally, and can be used instead of the computer to turn the antenna. Switching between operator and computer control of the rotor box is automatic, eliminating the need for the operator to do so. The circuit, an extension of K9AZG's "Automatic Beam Aimer" (*73*, November, 1982), uses 13 ICs and can be constructed by anyone with familiarity with digital circuits. I suggest reading K9AZG's article as it reviews the operation of the CDE control box.

Theory of Operation

The interface will begin to rotate the rotor as soon as a character is received from the computer. This character contains 8 data bits and can be calculated using a small subroutine or can be obtained from a lookup table.

As shown in Fig. 1, serial data is received by a Universal Asynchronous Receiver/Transmitter (UART) which converts the character to 8 parallel bits. Seven of the bits represent the desired beam heading and are transferred to the input of a digital-to-analog converter (D/A converter, or DAC).

The DAC generates a precise dc voltage specified by the digital input. This voltage represents what the control-box meter should read when the rotor is correctly aimed. This voltage is applied to one input of a comparator, with the other comparator input connected to the control-box meter. These two voltages are compared and an output voltage is generated which is equal to the voltage difference between the comparator inputs.

A negative output voltage indicates the rotor must be turned clockwise (CW). A positive output voltage indicates the rotor must be turned counterclockwise (CCW). Sensing the polarity of the voltage is accomplished using two comparators, one to sense negative polarity and one to sense positive polarity.

One comparator output drives the CW relay and the other drives the CCW relay. The contacts of these relays are in parallel across the rotation switches in the control box and therefore are able to turn the rotor. Brake release begins as soon as a character is received and ends shortly after the correct heading is reached in order to allow for rotor coasting.

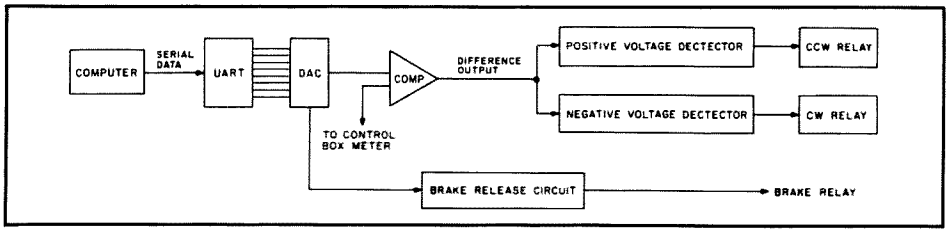

Fig. 1. Block diagram.

Construction

I have several suggestions which will save a great deal of time in building and testing this project. I strongly recommend that those building this project use wire-wrap construction. Point-to-point wiring is slow and messy, while design of a PC board requires a great deal of time. Wire-wrapping is fast, clean, and easy to learn. An electric wrap gun is cheap and will pay for itself within the first few hours of construction. Along with the gun, you will need an unwrap tool for correcting inevitable mistakes, as well as a special tool for stripping the wire.

The wire comes in different colors to make construction easy. Three small spools, each a different color, will be sufficient for this project. Use a different color wire for each stage and you will work faster with fewer mistakes. These items are available at Radio Shack and will become valued tools in the shack. [*I use an OK wrapping pencil available for about $30 from Jameco—it automatically strips the wire.* —Ed.]

Of equal importance is the construction technique. Since this circuit has several stages, I built and tested them one at a time. This way I knew exactly what worked as I went along. The most important benefit of this method is the opportunity for the reader to completely understand what each stage does. Other people's designs can be tough to get working without a logical approach. Build and test one stage at a time and you will be glad you did. In the following sections of this article, I have used this method so that testing can be performed as each stage is built.

Power Supplies

Four power-supply voltages are required, as shown in Fig. 2. The output of a 12.6-volt transformer is rectified and filtered to produce approximately +15 volts dc. This voltage is applied to the input of the positive voltage regulators and the relay coils. It's good practice to obtain relay drive voltage before the regulators since the relay coils present a heavy load in comparison to the logic and can produce transients on the supply lines.

+5- and +12-volt outputs are easily obtained using Texas Instruments regulators from Radio Shack. They should be heat-sunk to avoid thermal failure.

The +10-volt reference output supply may be obtained either of two ways. I used a 723 regulator and adjusted R2 to obtain 10 V. I had intended to use the less complicated LH0070 regulator, but none was to be found locally. If it's available, it will save some time and space; however, the 723 works equally well.

The −12-volt supply consists of a 12-volt transformer rectified and filtered to obtain approximately −15 volts for driving the negative regulator.

In order to test the supplies, disconnect the outputs from any loads and apply 120 V ac to the transformers. Feel the four regulators to be sure that they are not hot (warm is OK). Measure the unregulated voltage at the output of the bridge rectifiers. It should be at +15 or +20 V dc for the positive supply and −15 to −20 V dc for the negative supply.

Next, measure the +12-, +5-, and −12-volt regulator outputs. Finally, measure the output from the 723 regulator and adjust R1 for exactly +10-volts output from the regulator. Any supply output which is over the specified output probably has a wiring error or a bad IC. Any supply with a low output voltage should be checked to see if its output is being heavily loaded (it would also be very hot). Also check the input voltage to see if it's at least 2 volts greater than the rated output.

Serial-Data Port

I designed the serial-data input shown in Fig. 3 to be as flexible as possible for easy connection to various computers. Only two wires are required by the interface: receive data and ground. The serial-data input expects to see either EIA RS-232-level mark and space (−3 to −12 and +3 to +12 volts, respectively) or TTL-level input (0 volts and +5 volts). If an RS-232 interface is used, it may be necessary to make the interface look like a modem to the computer by connecting pins together on the DB-25 connector at the interface. This is accomplished by connecting pin 5 (clear to send), pin 6 (data set ready), and pin 8 (data carrier detect) to +12 volts. An alternate approach is to connect pin 4 to 5 and pin 6 to 20, as shown in Fig. 3. These jumpers are only required if the computer requires handshaking in order to output data.

RS-232-level data is converted to TTL-level (5 volts) data with an MC1489 line receiver and applied to the input of a UART. If the computer outputs TTL-level data rather than RS-232, it will be necessary to check whether the output data is inverted. In order to do this, measure the voltage at the computer's serial-data output. When no characters are being sent, the line should be in the mark state and be at +5 volts. When a character is being sent, the line should alternate between +5

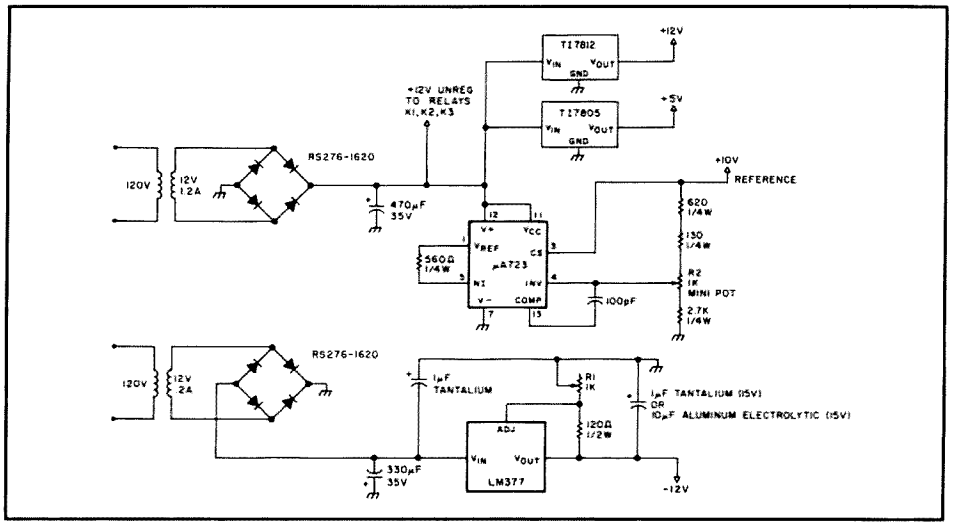

Fig. 2. Power supply.

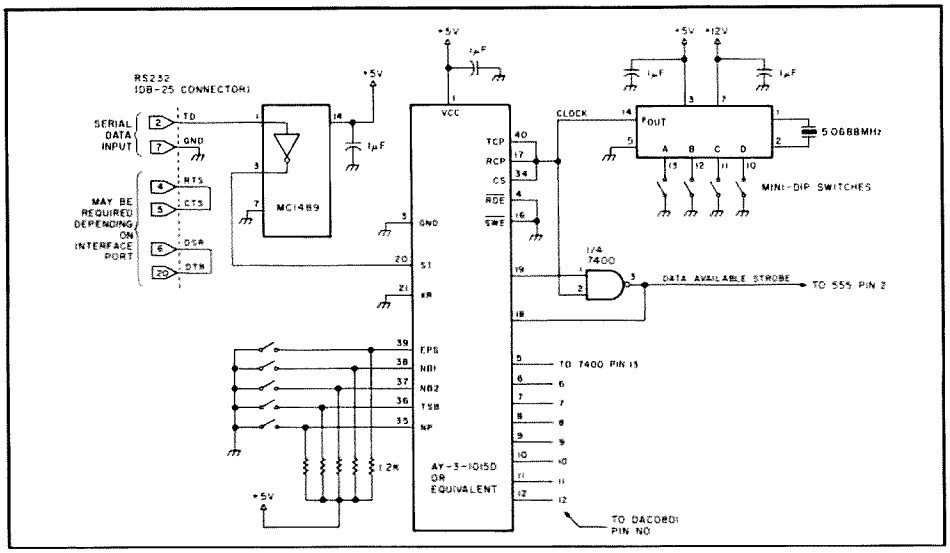

Fig. 3. Serial data input.

and 0 volts. If this is the case, disconnect the 1489 and apply the TTL-level data to the serial input of the UART. If the computer output is 0 volts when idle, apply TTL-level data to the input of the 1489.

The UART is a communications IC which receives, transmits, and buffers serial data. It is divided into two parts, a transmitter and a receiver. In this interface, only the receiver is used. Its purpose is to accept a character consisting of several bits sent sequentially and store these bits in a buffer. The bits are then output on pins 5 through 12 of the UART. For example, the transmission of 0111 1111 (7FH) from the computer to the UART is accomplished one bit at a time on the serial-data port. Pin 12 of the UART will assume the logic level of the least significant bit (the rightmost bit), in this case a logic 1, or +5 volts. The remaining 7 bits are applied to pins 11 through 5, with pin 5 being the most significant bit.

The serial character consists of several parts, each of which can be varied to accommodate specific purposes. The first bit sent is called the start bit; it is used to signal the UART that a character is coming in. Between 5 and 8 data bits are used, 7 to carry the beam heading and one to control the brake. Following the last data bit is one bit used for error-detection; this is called the parity bit. When odd parity is used, the computer will ensure that all characters sent will include an odd number of 1s. If, for instance, two data bits in the character are logic 1, the parity bit will be logic 1. If the three data bits are logic 1, the parity will be logic 0. A parity error will occur if a bit error occurs, as the wrong number of Is will be received. Pin 13 will go to logic 1, indicating the error. Finally, 1, 1-1/2, or 2 stop bits follow, signaling the end of the character.

Since there are many possible character formats, pins 35 through 39 are provided for setting up the UART. They are pulled up to logic 1 by 1.2k resistors and can be set to logic 0 by closing a DIP switch grounding the pin. It is an absolute necessity that the computer and UART be set up exactly the same, or the characters will be incorrectly received. The UART is flexible, so make it conform to the computer.

Parity must be disabled at the computer so that the parity bit is not transmitted. Open the switch tied to UART pin 35 so that it won't look for the bit. I closed the switch tied to pin 36 in order to set the UART for 1 stop bit. Opening this switch sets the UART for 2 stop bits. Pins 37 and 38 are set to logic one by opening the switches. The computer must also be set for 8 data bits and no parity. The state of pin 39 is irrelevant since pin 35 disabled parity.

As well as changing character format, it is possible to set the speed at which the character is received. Different speeds are made possible by applying different clock rates at pin 17, the receiver clock. These clock frequencies are generated by a baud-rate generator. Selection of a particular clock rate, and therefore UART speed, is accomplished with the switch settings on pins 10 through 13 of the baud-rate generator. See Fig. 4 for the proper switch settings for the speed you will run. I found 300 baud to be a good choice.

Testing the UART stage requires that 8-bit characters be output from the computer's serial-data port. Refer to the software section of this article and to your computer's user manual if you are unfamiliar with outputting hex characters. Testing is accomplished as follows:

Apply power and check to see that the UART and baud-rate generator are receiving their proper supply voltages. Now measure the voltages at the programming pins on the UART and baud-rate generator. Plus 5 volts indicates a logic one and an open switch on the pin. If a scope or logic probe is available, check to see that the baud-rate-generator clock output is running. Now transmit 0000 0000 (00H) from the computer to the UART and check to see that pins 5 through 12 are all at logic 0. Next transmit 1111 1111 (FFH) and make sure pins 5 through 12 are at logic 1.

If the outputs change when different characters are received but are not correct, it's probably that the format or speed is incorrect. If the outputs don't change at all when different characters are sent, the UART is not receiving. This can be checked by disconnecting UART pin 18 (reset data available) and typing it to +5 volts with a 1.2k resistor. Send a character to the UART and measure the voltage on pin 19 (data available). It should go to logic 1 as soon as a character is received and will remain at this level until pin 18 is momentarily grounded. If pin 19 never goes to logic 1, the UART is not receiving a character. Disconnect the resistor and reconnect UART pin 18 when this test is completed.

In operation, pin 1 of the 7400 goes to logic 1 when a character is received. On the next clock pulse, pin 2 of the 7400 goes to logic 1. At this point, both NAND-gate inputs are logic I, producing a logic 0 output on pin 3. This output is applied to the UART reset data available, which drops the data-available flag and allows the UART to receive another character. Pin 3 immediately returns to logic 1. This reset pulse on 7400 pin 3 is extremely short and difficult to see without a fast scope.

Digital-to-Analog Converter

Seven of the UART output pins are connected to the digital-to-analog converter (DAC) input pins. As shown in Fig. 5, the most significant bit (MSB) from the UART, pin 5, is not passed to the DAC since it is used to tell the interface that it is allowed to release the brake and turn the rotor. Each character received by the UART is converted by the DAC to an output current on DAC pin 4. By tying pin 4 to +10 volts through a pot, different voltages can be generated depending on the character received. Specifically, output voltage $=10\ V-[(2\ mA\ xR(D/256)]$, where R is the resistance of the pot (set for approximately 5k) and $D=128(B7)+64(B6)+32(B5)+16(B4)+8(B3)+4(B2)+2(B1)+(B0)$.

What this means is that 256 different output voltages between 0 and +10 volts can be generated by the DAC depending upon the input bits. Since only 7 bits are used to indicate the beam headings in the interface, 128 possible output voltages can occur. In order to keep the computer software simple, only 120 possible output voltages will be generated, 00H to 77H. Each of these output voltages corresponds to a specific beam heading. Since the rotor must turn through 360 degrees and 120 different output voltages can be generated, we see that the resolution of the interface is exactly 3 degrees. In operation, the MSB is set to logic 1 to allow rotation by releasing the brake. Therefore, it is necessary

to send the characters 80H to F7H to the interface.

In order to test the DAC, check to see that its +12-, +10-, and −12-volt supply inputs are operational. Now send 1111 0111 (F7H) to the UART and check to see that the DAC pins 6 through 8 and 10 through 12 are at logic 1. Pin 9 should be at logic 0 due to the 0 in the input word and pin 5 should be at logic 0 since it is grounded. Now measure the output voltage on DAC pin 4 and adjust R3 for exactly zero volts. This is the only way that R3 can be correctly adjusted. Now send 1000 0000 (80H) to the UART and check to see that DAC pin 4 is approximately +10 volts. Do not adjust R3 to set this 10-volt level. By setting this resistor, the DAC has been adjusted to output between 0 and +10 volts for digital inputs from 77H to 00H.

The output from the DAC is applied to the inverting input of a 1458 comparator. The non-inverting input is connected through a pot to the rotor-box meter. These inputs are compared and an output voltage is produced which is equivalent to the difference between input voltages. The polarity of the comparator output will be either negative or positive depending upon which input voltage is greater. For example, if the DAC output is +2.5 volts and the meter is +1.0 volts, the comparator output will be −1.5 volts.

Construct a test pot by connecting one side of a 100k pot to +12 volts and the other side to −12 volts. Connect the wiper of the test pot to the side of pot R4 labeled "meter input." The control-box meter should not be connected. With the test pot, it will be possible to simulate the voltages which appear on the meter of the rotor box. In order to test the 1458 comparator circuit, first check pins 4 and 8 to see that they are getting power. Send 1011 1111 (BFH) to the interface and check to see that DAC pin 4 is 5 volts. Adjust the test pot so that +5 volts appears on its wiper. Next adjust R44, the input attenuator pot, for +5 volts on its wiper so that it is not attenuating the meter input during testing.

Since the DAC is outputting +5 volts to the comparator and the meter input is at +5 volts, the comparator output should be 0 volts. Reduce the test-pot wiper voltage to +4 volts and check to see that the comparator output on pin 1 is −1 volt. Remember, 5 volts on the input from the DAC minus 4 volts on the input from the wiper equals −1 volt. Adjust the test pot for +10 volts on its wiper and check comparator pin 1 for +15 volts.

In short, the comparator output contains two pieces of information. First, the polarity of its output indicates which direction the rotor must be turned. Second, the magnitude of the output indicates how big the difference is between the actual and the desired direction.

Rotation Control

In order to translate the 1458 comparator output to contact closures for the rotor-control box, two comparators are used. One closes the CCW relay, K2, when the 1458 output is positive, and the other closes the CW relay, K1, when the 1458 output is negative. The contacts of relays K1 and K2 are in parallel across the CW and CCW rotation switches in the rotor-control box. R5 is a threshold adjustment which sets the maximum difference output on the 1458, which can occur before K1 or K2 is closed to rotate the antenna. In operation, this pot will determine how close to the desired direction the rotor will come before coasting to a stop.

Testing of this stage should be performed without any connection between the interface and the rotor-control box. Connect a jumper from unregulated +12 volts to the relay pow-

er wire so that K1 and K2 can be energized without closing K3 (see Fig. 5). This wire is connected to the side of the relay coil not connected to the transistor. Apply power and check for +12 volts on LM339 pin 3. Adjust R5 for approximately 1 volt on pin 4 of the LM339. Send 0111 1111 (F7H) to the interface and check for 0 volts on pin 4 of the DAC. Vary the input voltages on pin 3 of the 1458 by turning the test pot from one extreme to the other. The output on pin 1 of the 1458 should vary between +12 volts and −12 volts. When this output is positive and greater than the threshold voltage on pin 4 of the LM339, approximately 0.7 volts should appear on LM339 pin 2. This will drive Q2 into saturation, closing relay K2. When the 1458 output is negative, pin 1 of the LM339 will be approximately 0.7 volts, driving Q1 into saturation and closing K1. Make sure that K1 and K2 are not closed at the same time.

UART Pin #	Name	Function	
35	No parity	Logic 0	eliminates parity bit
		1	includes parity bit

		1 1	8
39	Odd/even parity	Logic 0	odd parity
		1	even parity

Table 1. UART configuration options. Closed switch = logic 0, open switch = logic 1.

Brake Circuit

At this point, the interface is nearly complete, as it is capable of receiving a character and rotating the rotor to the desired direction. The only remaining requirement is that the brake be released when the rotor is turned.

Looking at the schematic, one might wonder why so many components are used in releasing the brake. Consider what would happen if the operator wants to turn the rotor using the control box rather than the computer. After the rotor turns several degrees, the interface will detect that the rotor is no longer aimed in the direction last specified by the computer. The result would be that it would energize relay K1 or K2 in order to turn the rotor back to the correct direction.

This problem can be overcome by controlling K1 and K2 with the brake circuit. Coil voltage for these relays is interrupted by a set of contacts in K3, the brake relay. Unless K3 is energized, relays K1 and K2 will not close, regardless of what the comparators dictate. The purpose of the 555 timer and 7476 flip-flop is to energize K3 only for as long as is required to bring the rotor to the correct heading after a command from the computer. Once the rotor turns to the correct heading, the relays cannot be re-energized unless a character is received from the computer. Therefore, the rotor control box may be used without interference from the interface.

Operation of the brake circuit commences as soon as a character is received by the UART and the data-available reset is generated on pin 3 of the 7400. This strobe, which will occur every time a character is received, is applied to the 555 and 7476. The 7476 toggles to the on state, outputting a logic 1 on pin 15 which releases the brake. It will remain on until a logic 0 reset pulse is received on pin 3. The reset is normally generated when the rotor reaches the correct direction and K1 and K2 de-energize, allowing 7400 pin 10 to go to logic 1. Pin 8 of the 7400 will then go to logic 0, resetting the 7476 and applying the brake.

Several parts of this stage require explanation. When a character is received from the computer, the brake circuit will energize K3 before the DAC and comparators are finished energizing K1 or K2. Since the contacts of these relays would not be closed, the brake circuit will assume that the rotor is correctly aimed. It would then de-energize K3, stopping the rotation process before it started. The timer prevents the reset from reaching the 7476 for a second after the character is received, ensuring that the relays have time to energize.

Another function of the timer is to generate a reset if the computer tells the interface to turn a direction it is already aimed at. Addition of one gate of a 7400 at the output of the 7476 adds the capability of the computer to cancel or disregard a rotation command. Bit 8, the most significant bit of the character received by the UART, is used as a rotate-enable bit. It is applied to 7400 pin 13 and prevents the 7476 from releasing the brake unless it is at a logic 1. Therefore, to stop rotation, send any character to the interface with the most significant bit set to logic 0 (00H thru 7FH) and the relays will de-energize.

Testing of the brake circuit should begin by checking the 555 and 7476 for proper power-supply input. Turn the test pot to one extreme of its rotation and send 1011 1100 (BCH) to the UART in order to produce a large difference voltage at the output of the 1458 comparator. Notice the MSB is a logic 1 to release the brake. As soon as the character is received, 7476 pin 2 and 555 pin 2 should momentarily go to logic 0. Pin 3 of the 555 should go to logic 1. After a second, 555 pin 3 should return to logic 0. K3 as well as K1 or K2 should be energized due to difference-voltage output from the 1458.

Slowly rotate the test pot so that both K1 and K2 de-energize (the interface will think the antenna is correctly aimed). After a short coasting delay, K3 will also de-energize. The length of this delay should be set to at least a second by adjusting R6. In order to check to see that rotation can be canceled, turn the test pot to one extreme and send 1011 1100 (BCH) to the UART. K3 and either K1 or K2 will energize in order to rate the antenna. Send 0000 0000 (00H) to the UART and see that the relays drop out since the MSB is logic 0.

Installation and Adjustment

Before connecting the interface to the rotor control box, it is necessary that the interface be properly operating as outlined thus far. Disconnect the test pot but leave in the test jumper supplying +12 volts to K1 and K2. Open the rotor control box and locate the PC board which is attached to the back of the meter. Connect the positive lead to either side of the fuse on the PC board which is attached to the meter. Rotate the rotor back and forth and note that the dc voltage on the fuse varies with rotor direction. The voltage at this point tells the interface which direction the rotor is aimed. Connect the side of R4 labeled "to meter" to either side of this fuse. (*Not the 120-volt power fuse!*) Connect terminal #1 on the interface terminal strip to terminal #1 on the rotor box. Measure the resistance between interface ground and the control-box chassis. It should be about zero Ohms.

Apply power to the interfaced and turn to the rotor control box. Adjust R5 to obtain 1 volt on pin 4 of the LM339. Send 1111 0111 (F7H) to the interface and adjust R3 for exactly 0 volts on pin 4 of the DAC0801. Send 1000 0000 (80H) to the interface and check that the voltage on pin 4 of the DAC is between +8 and +10 volts. Using the control box, rotate the rotor fully clockwise to the south. The meter output voltage should be between +8 and +10 volts. With the rotor turned clockwise to the south, adjust R4 so that is wiper voltage is exactly the same as the voltage on pin 4 of the DAC0801. An easy way to do this is to measure the difference-voltage output on pin 1 of the 1458 comparator. Adjust R4 so that this voltage is exactly 0 volts. These adjustments have set the DAC and meter outputs to operate over the same range of voltages.

Instruct the interface to turn the rotor north by sending 1011 1100 (BCH) to the interface. K3 and K2 should energize. Turn the rotor north using the control box and note that K2 followed by K3 will drop out at some point during the rotation. The exact point at which K2 will de-energize is dependent upon the threshold setting of R5. This adjustment set how much before the desired heading is reached the rotor will begin to coast to a stop. Setting too tight a tolerance will cause the interface to hunt back and forth for an exact heading. I found a tolerance of about 5 degrees works reliably. The adjustment is made by turning the rotor 5 degrees clockwise from north using the control box and then sending 1011 1100 (BCH) to the interface. Adjust R5 so that K2 is just on the border of de-energizing.

Fig. 6. Matrix look-up table.

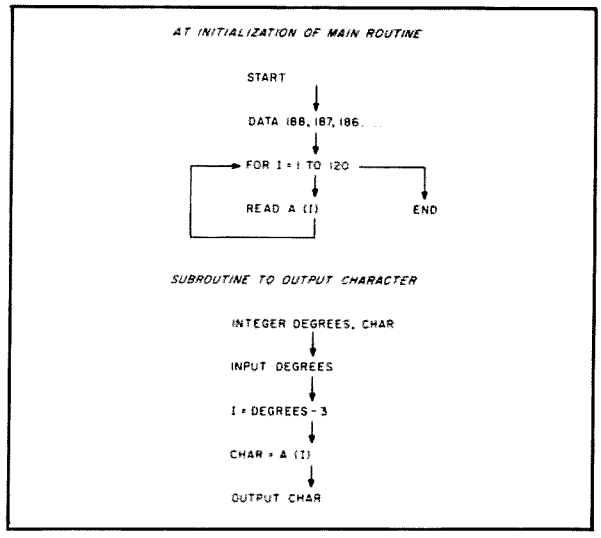

Fig. 7. Flowchart for look-up table in Basic.

Disconnect the test jumper and connect terminals 2, 5, and 6 on the interface terminal strip to terminals 2, 5, and 6 respectively on the rotor control box. Do not disconnect the wires already on these terminals. Relay K3 has two wires connected to its normally-open contacts labeled "to brake relay." These wires should be connected in parallel across the contacts of the brake-release switch in the rotor box. This will release the brake when K3 energizes.

Apply power to the interface and the rotor control box and send 1000 0000 (80H) to the interface and note that K3 and K1 will energize, turning the rotor clockwise to the south. After rotation has stopped, send 1011 1100 (BCH) to the interface and note that K3 and K2 will close, turning the antenna to north, where it will stop. Send 1111 0111 (F7H) to the interface and the rotor will turn counterclockwise to the south. Finally, test the stop function by sending the interface a command to turn followed by a 0000 0000 (00H). This will stop the rotation.

Software

Before reviewing the program which will send data to the interface, it is necessary to understand the software requirements. Normally, rotor direction is expressed as 360 points on a circle (called degrees). Zero degrees is north and the number of degrees increases with clockwise rotation. The interface uses a different system, however. This is due to the design of the meter circuit in the rotor control box. In this system there are 120 directions, each of which is 3 degrees in width. The software is able to control rotor direction by telling the interface to go to one of these direction.

Communication between the computer and the interface is in a binary string of 1s and 0s. Seven binary bits are required to specify 120 rotor headings, and the 8th (MSB) bit is used for brake control. The way the program specifies the string of bits varies with different computers and software packages.

In the hexidecimal system, 4 bits are grouped together to form a hex digit. Since 4 bits can form 16 different combinations, the hex digit must be able to represent all possibilities. This is accomplished by counting as follows: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F. Since we need to represent 8 bits, it will be necessary to form a word containing 2 hex digits. For use with the interface, the range of the word will be from 80 hex (1000 0000) to F7 hex (1111 0111), as shown in Fig. 6. Those that are writing the program in assembly language will send a hex word to the communications port of the computer.

A different method is used when running Basic. In this system, the decimal value of the output word is placed on the serial port. The decimal equivalent of the output string is calculated by assigning values to bit positions. The value of the 8 bit positions is as follows; 128, 64, 32, 16, 8, 4, 2, and 1. For instance, the equivalent of 1000 0010 is 128+2 or 130. Only 128 and 2 were counted since these were the positions where 1s occurred in the bit string. The decimal outputs corresponding to different directions are shown in Fig. 6. Check your software manual to determine how to send the character to your serial port.

I will describe two ways which the output character can be generated in software. Regardless of which method is chosen, I suggest that the program be implemented as a subprogram or subroutine. This way the software for driving the interface can be accessed at multiple points in a main program. The software will also remain constant regardless of which main program it is used with.

A simple program to implement is one which uses a look-up table to obtain the character to be sent to the interface. The table contains either hex or decimal output characters associated with different directions. The most elementary way of using the table would be for it to consist of 360 entries, each associated with a rotor heading in degrees. If, for instance, the software must turn the rotor to 70 degrees, it would go to the 70th entry in the table, obtain the character at that location, and send it to the interface. The output character for 250 degrees would be contained at the 250th memory location and so on. This system is easy to use because there is no need to relate rotor heading in degrees to the direction number and then convert to an output character. This is done when the table is written.

Since there are only 120 different directions, and therefore output characters, a table of this type would have each output character repeated 3 times in 3 adjacent memory locations. Since no purpose is served by wasting memory, the table can be reduced to 120 entries. The flowchart in Fig. 7 shows how a look-up-table program can be implemented in Basic. When the main program is started, the variables A(0) to A(120) are loaded with the decimal-output characters in the look-up table of Fig. 6. A(0) is loaded with 188, A(1) with 187, etc.

Also shown in Fig. 7 is a subroutine which retrieves output characters from the look-up table. When a rotor heading is received by this routine, an integer division is performed to obtain "I"—which is used as a subscript for A(I). The decimal-output character stored in A(I) is then output to the serial port. For example, suppose the rotor is to turn south to 180 degrees. The routine receives 180, then divides by 3 to obtain the integer 60. The decimal stored in A(60) is loaded into the variable "char" and sent to the serial port.

It is also possible to write this routine in assembly language. If this is done, the value of "I" is used as an offset from the base address of the look-up table.

Another way to generate the output character is to calculate it. Although more time will be required to run this routine, it requires less memory than the look-up table method. Fig. 8 shows the flowchart which creates the character through successive substations.

Regardless of which method is chosen, the software can be tested for proper output by inputting a rotor heading in degrees. Have the program print the character it would output to the interface. This way the software can be

tested without spinning the rotor back and forth.

Conclusion

When completed, the interface can be mounted in a case or inside the rotor control box on the bottom side of the chassis. If this is done, it will be necessary to fit the transformers and relays on top of the chassis. I experimented by using miniature relays instead of those specified and found that they can work for a limited time before the contacts melt. Don't waste time and money on them.

For those who would like the interface to notify the computer that the proper heading has been reached, all that needs to be done is to add a line driver on the serial output of the UART. Let the reset that goes to the 7476 trigger the UART transmitter. The character that the UART sends to the computer can be selected using the UART transmit-data pins.

Another idea that I've been thinking about is an improved brake circuit that detects when the rotor has coasted to a stop (rather than waiting several seconds and applying the brake). A differentiator could be constructed so that it outputs a logic 1 as long as there is a change taking place on the meter. When the meter stops changing, the circuit would output a 0. Therefore, when the rotor coasts to a stop, the differentiator output goes to logic 0 and the interface applies the brake. If the differentiator output were then connected to a circuit which looks at the comparator output voltage from the 1458, it would be possible to detect a stalled rotor. Stalling would be indicated if the comparator had a difference voltage present on its output but rotor motion was stopped. I did not include this in the article as it wasn't essential to operation.

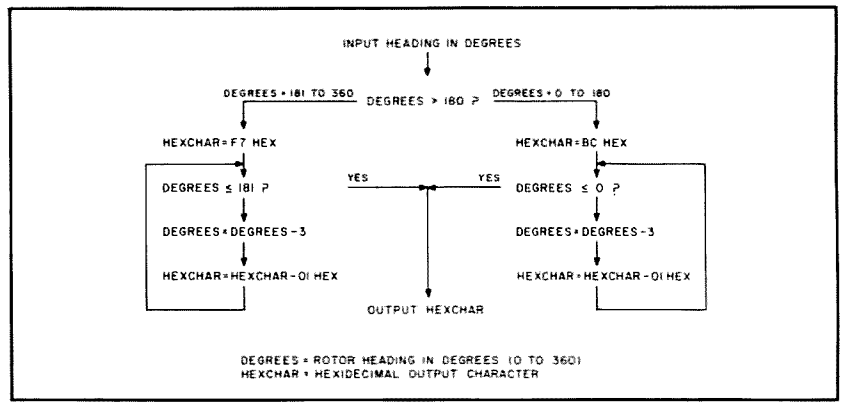

Fig. 8. Calculation of output character.

A final thought regarding the computer software. There are numerous applications for this circuit which can be implemented in the main program: rotation linked to a great circle program, direct heading entry via keyboard, timed rotation slaved to the computer clock (satellite tracking), etc. Who will be the first to implement total computer control of the shack? All the pieces are available: computer-interfaced HF rigs, CW/RTTY readers/generators, and now an antenna.

Good luck, and happy rotoring! ■

Parts List

ICs			
1	TI7812 regulator (12v)	RS276-1771	$1.59
1	TI7805 regulator (5v)	276-1770	1.59

CONTESTS

Robert W. Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL VHF QSO PARTY
Starts: 1800 UTC June 14
Ends: 0300 UTC June 15

The object of this ARRL-sponsored contest is to work as many amateur stations in as many different ARRL sections and countries as possible using authorized amateur frequencies above 50 MHz. Note that these rules were taken from previous year's contests, with 902 MHz now counting 3 points. No other changes were anticipated. Check *QST* for any last-minute changes.

Operating categories include single operator using multi- or single band, or multi-operator. Single-operator stations must use one person for all operating and logging functions. Single-operator stations may submit single-band scores for 50, 144, 220, 432, and 1296-and-up categories. Contacts may be made on any and all bands without jeopardizing single-band entry status. Such additional contacts are encouraged and should be reported.

Multi-operator stations must locate all equipment (including antennas) within a 300-meter circle.

Stations may be worked once per band regardless of mode. Each QSO must be acknowledged; one-way exchanges do not count. Foreign stations may work only stations in the U.S., Canada, and U.S. possessions for contest credit.

Retransmitting either or both signals, or use of repeater frequencies is not permitted. Contest entrants may not transmit on repeaters or repeater frequencies on 2 meters to solicit contacts. Use of the national calling frequency, 146.52, or immediate adjacent guard frequencies is also prohibited. Only recognized simplex frequencies may be used, such as 144.90–145.10; 146.49, .55, and .58; and 147.42, .45, .48, .51, .54, and .57. Local option simplex channels and frequencies adjacent to the above that do not violate the intent of the contest rules or the spirit and intent of the band plans as recommended in the *ARRL Repeater Directory* may be used for contest purposes.

All operation must be fixed, portable, or mobile and under one call from one ARRL section. A transmitter used to contact one or more stations cannot be used under any other call during the contest period, with the exception of family stations where more than one call is assigned to one location by FCC/DOC. Also, one operator may not give out contest QSOs using more than one callsign from any one location.

Only one signal per band at any given time is permitted, regardless of mode. While no minimum distance is specified for contacts, equipment should be capable of real communications (i.e., able to communicate over at least a mile). Multi-operator stations may not include QSOs with their own operators except on frequencies higher than 2.3 GHz. Even then, a complete, different station must exist for each QSO made under these conditions.

Above 300 GHz, contacts are permitted for contest credit only between licensed amateurs of Technician class or higher using coherent radiation on transmission (e.g., laser) and employing at least one stage of electronic detection on receive.

EXCHANGE:

Name of section, VE province, or DX country. Must be acknowledged by both operators for credit by either.

SCORING:

Count one point for each complete 50- or 144-MHz QSO, 2 points for a 220- or 420-MHz QSO, and 3 points for 902-MHz or 1215-MHz-and-above QSO. Crossband QSOs do not count.

Mutipliers count once per band: each ARRL section in the contiguous 48 states (63 max.), each Canadian province (12 max.), and each DXCC country (excluding W and VE).

REPORTING:

Entries must be postmarked no later than July 11th and sent to: ARRL Headquarters, Newington CT 06111. Official entry forms are available from the same address for an SASE. Usual ARRL disqualification rules apply. Usual awards to top scorers in each ARRL section, some limited to where significant effort or competition is evidenced. Multi-operator entries are not eligible for single-band awards.

WORLDWIDE SOUTH AMERICA CW CONTEST
Starts: 1500 UTC June 14
Ends: 1500 UTC June 15

Sponsored by *Electronica Popular* magazine of Rio de Janeiro, Brazil, this contest will be held annually on the second complete weekend of June. Use all bands from 160 through 10 meters on CW only; crossband contacts are not valid. Work stations worldwide. Entry classes include single operator/single band or all bands, and multi-operator/single transmitter (multiband only).

EXCHANGE:

RST and consecutive QSO number starting with 001.

SCORING:

Each QSO within your own country counts zero points—it only counts as a multiplier. QSOs within same continent are 2 points; QSOs outside your continent are 4 points each. Contacts with South American stations (only for outside South America) count 8 points per QSO. Multipliers are the number of different DXCC countries and different South American prefixes worked on each band. Final score is the total QSO points multiplied by the sum of total multipliers in each band.

AWARDS AND ENTRIES:

Certificates will be awarded to the three top-scoring stations in each class for each country with a reasonable score provided. A separate log for each worked band must be sent no later than August 31st to WWSA Contest Committee, PO Box 18003, 20772 Rio de Janeiro, RJ, Brazil. Include a self-

ZERO BEAT

NEWSLETTER OF THE MONTH

This month's winner is Zero Beat, the newsletter of the Hampden County (Massachusetts) Radio Association. Most of the most recent issue is taken up with a reprint of an article from *73* (that isn't why it won–we're trying to make a point here). If you see something in *73* that you'd like to reprint in your newsletter, drop us a note saying what you'd like to do. That's what Zero Beat did, and we were only too happy to help 'em out.

To enter your club's publication in *73*'s Newsletter of the Month Contest, send it to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: Newsletter of the Month.

addressed envelope with IRCs for a copy of the results. (*Note: See Brazil column in 73 International.*)

ARRL FIELD DAY
Starts: 1800 UTC June 28
Ends: 2100 UTC June 29

Note that these rules were taken from previous years' contests and no changes were anticipated other than the availability of the 24-MHz band. Check *QST* for any last-minute changes.

Sponsored by the ARRL, the contest is open to all amateurs in the ARRL Field Organization plus Yukon and NWT. Foreign stations may be contacted for credit, but are not eligible to compete. The object is to work as many stations as possible under less-than-ideal conditions. Operating times are limited depending on your operating class; check rules below.

Entry categories are classified by the maximum number of simultaneous transmitted signals, followed by the designation of the nature of the individual or group participation. Below 30 MHz, a transmitter must remain on a particular band for at least 15 minutes once used for a contact on that band. During this 15-minute period, the transmitter is considered to be transmitting a signal (even if it is not) for purposes of determining transmitter class. Switching devices are prohibited.

Class-A consists of club and non-club portable stations specifically set up for Field Day. Such stations must be located in places that are not regular station locations. They must use neither facilities installed for permanent station use nor any structures installed permanently for FD use. Stations must be operated under one callsign and under the control of a single licensee or trustee for each entry. All equipment (including antennas) must lie within a 300-meter circle. All contacts must be made with transmitters and receivers operating independently of commercial mains. Entrants who, for any reason, operate a transmitter or receiver from commercial mains for any contacts will be listed separately at the end of their class.

Any Class-A group whose entry classification is two or more transmitters (non-Novice) may also use one Novice/Technician operating position (Novice bands only) without changing its basic entry classification. This station (including antennas) should be set up and operated by Novice and Technician licensees and should use the callsign of one of these operators.

Class-B consists of non-club portable stations set up and operated by not more than two licensed amateurs. Other provisions are the same as for Class-A.

Class-C consists of mobile stations in vehicles capable of operation while in motion and normally operated in this manner, including antenna. This includes maritime and aeronautical mobiles.

Class-D consists of stations operating from permanent or licensed station locations using commercial power. This group of stations may count only contacts made with Class A, B, C, and E Field Day groups for points.

Class-E stations are the same as Class-D except they use emergency power for transmitters and receivers. They can work stations in all classes.

Operators participating in FD may not contact for point credit the FD portable station of a group with which they participate. Any station used to contact one or more FD stations may not be used under any other call during the FD period, except for family stations.

Each phone and each CW segment is considered a separate band. All voice contacts are equivalent, and RTTY/ASCII is counted as CW. A station may be worked once on each band; crossband contacts are not allowed. The use of more than one transmitter at the same time in a single band is prohibited, except that a Novice/Technician position may operate on any Novice band segment at any time. No repeater contacts—but the 24-MHz band may now be used.

EXCHANGE:

Stations in any ARRL section send Field Day operating class and ARRL section. A four-transmitter station in NJ would send "4A NJ." Foreign stations send RS(T) and QTH.

SCORING:

Scores are based on the number of valid contact points times the multiplier corresponding to the highest power used at any time during the FD period, plus bonus points. Phone contacts are one point each; CW contacts are two points each. Power multipliers are: 5 for using a dc input power of 10 W (20 W PEP) or less (or 5-W-dc output/10-W-PEP output) if a power source other than commercial mains or motor-driven generator is used; 2 for using a dc input power of 200 W or less on CW and 400 W PEP or less on SSB; 1 for using anything higher.

Batteries may be charged while in use for Class-C entries only. For other classes, batteries charged during the FD period must be charged from a power source independent of the commercial mains.

Bonus points will be added to the score (after the multiplier is applied) to determine the final score. Only Class-A and -B stations are eligible for bonuses:

1) *100% Emergency Power*—100 points per transmitter for 100% emergency power. All equipment and facilities at the FD site must be operated from a source independent of the commercial mains.

2) *Public Relations*—100 points for public relations. Publicity must be obtained or a bona fide attempt to obtain publicity must be made, or operation must be conducted from a public place (such as a shopping center). Evidence must be submitted in the form of a clipping, a memo from a BC/TV station that publicity was given, or a copy of material that was sent to news media for publicity purposes.

3) *Message Origination*—100 points for origination of a message by the club president or other FD leader, addressed to the SM or SEC, stating the club name (or non-club group), number of operators, field location, and number of ARES members participating. The message must be transmitted during the FD period, and a fully serviced copy of it must be included with the FD report. The message must be in standard ARRL message form or no credit will be given.

4) *Message Reply*—10 points for each message received and relayed during the FD period, up to a maximum of 100 points. Copies of each message, properly serviced, must be included with the FD report.

5) *Satellite QSO*—100 points can be earned by completing at least one QSO via satellite during the FD period. The repeater provision is waived for satellite QSOs and a satellite station does not count as an additional transmitter. Show satellite QSOs as a separate band on the summary sheet.

6) *Natural Power*—FD groups making a minimum of 5 QSOs without using power from commercial mains or petroleum derivatives can earn 100 points. This alternative power source also includes batteries charged by natural means (not dry cells). The natural-power station counts as an additional transmitter. If you do not want to change your entry class, take one of your other transmitters off the air while making the natural-power QSOs. A separate list of natural-power QSOs should be enclosed with your entry.

7) *W1AW Message*—A bonus of 100 points will be earned by copying a special ARRL FD bulletin sent over W1AW on its regularly announced frequencies just before and during FD. This message can be received directly from W1AW or by any relay method. An accurate copy of the received message should be included in your FD report.

REPORTING:

Entries must be postmarked by July 24th; no late entries can be accepted. A complete entry consists of a summary sheet and a list of stations worked on each band/mode during FD, plus bonus proof. The list of stations worked on each band or mode may take the form of official ARRL dupe sheets or an alphanumeric listing of callsigns worked per band and mode. This list may be computer generated. Incomplete or illegible entries will be classified as check logs. A copy of FD logs should be kept by your FD group but should not be sent in unless specifically requested by ARRL. Normal ARRL disqualification rules apply.

All entries and requests for official forms should be addressed to: ARRL, Newington CT 06111. Include a 9 x 12 self-addressed envelope with 3-oz. postage for a complete Field Day entry package.■

HAM HELP

Does anyone know where I can get two of the vinyl cases that were available in Canada for awhile for the ICOM 2AT and 4AT with BP-5 batteries? I'm also looking for information on SSTV—right now I can only receive. I need active frequencies to monitor.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Ahem, now, if you all will just kind of hum along...

Old Macintosh had some disks,
E-I-E-I-O
And on each disk was a program,
E-I-E-I-O
With a spreadsheet here,
And a data base there,
Paint a house,
Click a mouse,
Even programs for his spouse;
Old MacIntosh had some disks,
E-I-E-I-O
But when he wanted TTY,
E-I-E-I-O
There was no program he could buy;
E-I-E-I-O
So he checked on CIS,
And the BBS,
Log on in,
Search around,
Not a damn thing he has found!
Then Old Mac had one last hope...
Write to RTTY Loop! [Lope?–Ed.]

Only one problem, I am hard pressed to find anything either! I have received several letters in the last few months, all of which are asking for help in putting a Macintosh computer onto RTTY. Agust Bjarnason TF3OM in Gardabaer, Iceland, is just one of the hams trying to get onto MacRTTY. Sorry to say, but I have asked around to all my usual sources, including HamNet on CompuServe, and have come up blank. As of today, even the sysop on that system acknowledges that MacRTTY programs have been few and far between.

Well, are any of you out there willing to share your secrets? There must be someone who has interfaced a Mac to RTTY. I know there are many more who want to find out. Please drop me a line at the above address, and I will pass along the information to the mass MacMultitudes (sorry!).

One system I have obtained some recent information on is the "expanded" CoCo. A few months ago, I reviewed several accessory boards available for the Radio Shack Color Computer® which added a true serial and parallel interface, real-time clock, and 80-column display. All of these boards were produced by PBJ, Inc., and appeared to represent real improvements to an already fine machine.

With the introduction of the new version of the OS-9 operating system, several changes have surfaced with these boards, and I would like to quote you from a letter received from Donald Beane of PBJ. In a press release, he states, "effective February 1, 1986, we started shipping a new version of the WordPak. It is being manufacturered for Radio Shack's new version of OS-9, Rev. 2.0, and is available through their Express Order Catalog. In order to conform with Radio Shack's planned expansion devices, the new WordPak has been relocated to a new address (HFF76-79). This was required to avoid conflict with existing and/or planned devices. The cartridge is essentially the same as the original WordPak, except that it provides the larger character matrix of the WordPak II, and inverse video is implemented in the same manner as on the WordPak II. The price of the WordPak-RS is $99.95 and it is supplied with the OS-9 driver."

Mr. Beane indicated that nei-

Table 1.

ther the original WordPak nor the newer WordPak II will be produced any longer, and that "owners of WordPaks, WordPak IIs, and WordPak-RSs should contact the individual software houses with respect to specific applications software."

While there will be updated drivers to install older WordPaks and PC-Paks into newer systems, "there will be no driver module or update for the 2SP-Pak. The reason for this is that the driver is built into OS-9 Ver. 2.00.00."

I cannot speak as to any of the new drivers; I have yet to see any of them myself. I am aware of several posted in the data libraries of CompuServe but have not looked at those yet, either. If you are a user of one or more of these boards, you might want to drop PBJ a line at their new address, 503 East 40th Street, Paterson NJ 07504, attention Mr. Donald Beane. Be sure to tell him you are interested in the information printed in this column.

Hardly a month goes by that one ham or another does not write me and request information on press wireless frequencies that can be copied on RTTY. Often, my response has been a reference to one of the several books on the market that provide extensive lists of such frequencies. This time is different. Thanks to Scott, the sysop of CompuServe's HamNet, Table 1 is a rather extensive list of some of the signals he has logged over the last few years. This list is from personal monitoring over the last 10 years and is not copied from any other lists. These press stations all transmit in English—some all the time, others just occasionally.

In the table, the "SB" column indicates USB or LSB to be selected for normal copy. The apostrophe next to the L or U indicates that the station is still on the air as of the beginning of last year.

The "SH" column indicates the shift (Mark-to-Space frequency difference) used. Note that most use 425-Hz shift.

The "BD" column indicates the baud rate, not words per minute. This is standard Baudot RTTY code. Most foreign stations use "FIGS J" as the bell and "FIGS S" as the apostrophe, which is the reverse of American machines.

The "M" in the BD column indicates that the station is a frequency-division multiplex (FDM) transmission, usually with 16 subcarriers. The shift is usually 85 Hz, and many terminal units will not copy this. Receiving these FDM stations with the bfo off sounds like a buzz-saw. These stations are the best source of AP/UPI news, quite similar in format to the wire-line press service sent to radio stations. The best way to tune these in is to select USB and tune onto the station from the high-frequency side to the uppermost subcarrier. This subcarrier is usually the one carrying the news.

The "SVC" column shows the abbreviation of the news service.

The "CALL" column is obvious. Not all stations give identify with a callsign. Some use the same callsign on all frequencies at once, and some have calls for each frequency in use, but do not indicate which call is for which transmitter.

Not all stations of a particular service carry the same text. The VOA, for example, carries as many as four different "programs" at the same time. The ARF, however, has the same text on all four frequencies at once.

I have not given times of transmissions. That is too difficult to pin down accurately. Many stations are on continuously.

The frequencies given are within 2 kHz. Some stations do slide up or down a little and reverse their mark and space frequencies on occasion. My receiver readout also does not include the amount of bfo offset (about 1.5 kHz).

Happy tuning. . . de K9EUI!

Now, if all of my stateside readers will forgive me, let me stay overseas for awhile. Jose Vargas HP1XJZ has been trying to get onto RTTY from Panama City, Panama, with his friend Peter HP1XPM. He has a few questions about specific items of equipment advertised for RTTY and packet interfacing. I know I have said this before, Jose, but I try to print whatever information I receive. If you have not seen a particular piece of gear mentioned here, it is because I have not received anything—not personal experience, users' input, or even a manufacturer's blurb—on that item. I try not to review from ads. Check through some back issues and see if what you're looking for is not there; be sure to let the manufacturers know that you would appreciate reading about their products in RTTY Loop before plunking down hard-earned money.

Bill Pearson writes from Upper Hutt, New Zealand, (I have a dermatologist friend by that name, who happens to be a ham as well, here in the Baltimore area) asking about several RTTY programs for the Apple II+ computer. I mentioned the new source for one of them, SuperRATT, a few months back but have heard nothing about the so-called "Galfo" program. He relates that one of the difficulties he faces is that a program which costs $140 here sells for NZ$280 there, and he has to pay for it before even seeing if he likes the way it works. Anybody around willing to stick a hand out and help a brother on the other side of the world?

Another reader in yet another corner of the globe is Gilbert Marazzini in Milan, Italy. Gilbert relates his enjoyment with the materials presented in this column and appears to be interested in learning more about some of the RTTY basics. Don't go anywhere else, Gilbert, there will be more to come, right here.

Dr. Girish Shah, in Ahmedabad, India, has been trying to put a C-64 computer onto RTTY, and it seems that this column and the magazine that contains it are about the only sources for RTTY information available to him. I do hope that some of the material presented here over the last few months has helped, and I look forward to hearing about your success on the Green Keys.

"Green Keys." I wonder how many of you newcomers know where that one comes from? I think I'll just let it dangle for now.

Another Apple user in another land is Geoff Dover G4AFJ in Leicestershire, England. I am sending Geoff the current reprint list, at his request, which details some of the materials gleaned from past columns. The list can be yours, as well; just send a me a self-addressed, stamped envelope to the address at the head of this column and ask for the current reprint list. Naturally, other comments, questions, and prods are welcome at the same time.

The last ham on this whirlwind trip around the world is Alex Deligiannis SV8QG in Chios, Greece. Alex is the proud owner of a CoCo and believes he is the only one in SV-land trying to put one on the air. Well, again, I hope that some of the material I have presented here helps. I have planned some specific programming help for the CoCo if there is sufficient interest. With the paucity of programs comparable to those on other systems, there should be some demand here for a CoCo RTTY program that would be able to access disk functions and have a few bells and whistles to boot. Let me hear all of your opinions.

Now, take a deep breath folks and hear this. This month begins the *tenth year* of this column in *73* Magazine! That's right, TEN YEARS! Wow! I do want to take a moment to thank Wayne Green, without whose foresight many of the developments we take for granted might not have come to pass and who helped me get this column started—back in the dark ages. And my sincere thanks to each and every one of you, the readers of *73*, who have pushed our hobby to the technological limit, then broken even that limit, only to push ahead to a new future.

Table 2. SVC abbreviations.

As always, I remain available to you, either by mail at the address at the top of the column or on CompuServe, with my user number 75036,2501. If you want to get to me on CIS, EasyPlex (E-mail) is the best way. Messages left on HamNet or the CoCo or OS-9 SIGs may get to me as well, but they depend on my being there to see them before they scroll off the system. Remember, for those of you who send questions via the USPS, a self-addressed, stamped envelope is required if you would like a personal reply; otherwise, watch the column for a reply. Don't forget that I write each column about two to three months before you see it, though.

Summer's coming, with Field Day, picnics, and swimming parties. Who's going to be the first with a terminal at poolside? Send me a picture, then look for it in next winter's RTTY Loop!■

NK6K > PACKET

Harold Price NK6K
1211 Ford Ave.
Redondo Beach CA 90278

COMING ATTRACTION

Wake the kids and call the neighbors. The August issue of *73* is going to be all packet! And no, it won't just be this column with a thyroid condition. Nine or ten packet people will address such topics as: Intro to Packet, Intro to Networking, Better HF Operations, Packet Common Sense Operating Guide, Packet in Space, How to maintain digipeaters up where the air is thin, How to be a bulletin board/mailbox sysop, and more. For those of you who are worried that the inmates have finally taken over the asylum, don't worry; *73* will return to its regular fare the next month.

Packet Basics

For this section, I take as my text *73* Magazine, April 1986, page 82, RTTY Loop column. I'll review the question "What does packet provide to justify the cost?" and touch on some of the differences between RTTY, AMTOR, and packet. We know that packet is used to move characters between ham stations—something RTTY and AMTOR already do. What makes packet different?

Digression one. It is not my goal here to rate one mode over the other. Comparing the three modes is a bit like comparing apples to oranges to pears anyway. Each was designed for a different purpose—to solve different problems at widely separated points in history. More importantly, the actual implementation of each mode by the hardware and software in whatever device you've chosen to use can have a far greater effect on performance than the mode itself. A poorly implemented version of AMTOR software, or a packet controller with an inferior modem, will result in less data, or more bad data, than a well executed RTTY package.

Digression two. If you like using RTTY, don't let anyone talk you out of using it just because he says the mode is outdated. Whether it is or isn't is not the point, and that topic will not be debated here. Even though many in the RTTY world have changed over to the quiet tube-based RTTY systems, people still like using the old moving-parts gear for the challenge of bringing it up and keeping it running. The RTTY Loop column still carries information on how to get vintage electromechanical teleprinters on the air. If it's fun, I'm all for it. Some folks like whirring gears, others like flashing lights. While Part 97 tells us to provide emergency communications, extend the radio art, improve our skills, and enhance international goodwill, nowhere does it say that we can't have a good time doing it.

Recall the question "What *does* packet provide, and what is the cost?" Let's look at the easy part first: What does it cost? To get an idea of what the RTTY-experienced ham would consider cost-effective, I went to see my friend Lee Hallin WB7SND. He has managed to stay single and hasn't been forced to throw away things he'd rather save. His archives of *73*, therefore, are much larger than mine. We went back to the issue containing the first appearance of the RTTY Loop column, June 1977. This was a time when computer-based RTTY was just gathering steam. I'll compare RTTY prices in that year to the price of getting on packet in the year that this packet column first appeared, when packet was beginning to gather momentum. In the June 1977 issue, I found two references to the price of RTTY gear. The column intro said, "a complete RTTY station can be assembled for under $100." An ad near the middle had recently new TTY-33s (usable on RTTY by the strong-willed) for $850. Comparing the purchasing power of the dollar between 1977 and June 1985 (I got this data from the 1986 *World Almanac and Book of Facts*, page 51, the closest I could find in '86), you'd need at least $158 in 1985 money to equal $100 in 1977; $850 in 1977 is $1347 now.

Can you get on packet for $158 now? Sure can! A $50 surplus Xerox 820 board, a $10 keyboard, a $15 monitor, a FAD board from TAPR, the FADPAD software from FADCA, a $20 surplus modem, and you're on the air. In 1986, this is known as "the hard way." There are several complete TNC kits available in the $160 range. Put it together, plug it into the computer you probably already have, and you're on the air. Don't have a computer? Check the next swap meet; you should be able to pick up a glass-TTY (dumb terminal) for way under $100. Commodore C-64s are around $99. Don't like kits? Some assembled and tested TNCs are only $30 more.

If you already have a C-64, $219 gets you CW/RTTY/AMTOR *and* packet with AEA's PK-64 (reviewed in February's *73*). That's $129 in 1977 money. The same price or less gets you a packet-only unit that will work with any computer that draws less than 30 mA. You can run your TNC from the same 9-volt cell that you use to run your flashing LED callsign badge. A manufacturer new to the packet market has been advertising an assembled and tested packet controller for a price in the low hundred dollar range, but since I haven't seen one yet (3/31/86), I can't comment on it.

The price for a good packet unit and the price of a good RTTY or AMTOR unit are about the same. Depending on the features you can live without and how hard you are willing to work to scrounge parts, packet can be had for less than $158. Note that the above discussion, like the one in 1977, assumes you already have a radio. Just as RTTY would soon boom after 1977, packet is in a rapid growth phase now. Expect to see minimum featured TNCs available for less than $100 soon, while TNCs with more features will be in the $150 to $300 price range. All of the prices mentioned here may be different by the time you see this, so check around.

Now to the more interesting part of the question, "What does packet provide?" Last month's column gave references to technical information on what packet provides. This month, I'll discuss some of the major obvious features the operator sees.

The most obvious differences stem from "packetizing," breaking up your data into chunks. Packet controllers (TNCs) move your data around in chunks of 80 to 128 characters on the average. This process goes on in the background. In most cases, you need not be aware that it is happening; you just keep feeding characters to the TNC.

There are several methods you can use to control the packetizing process. One way is by the use of a special character that tells your TNC to take up all of the characters you've entered to that point and make them into a packet. The special end-of-packet character can be specified by the user (with a command called SENDPAC on TAPR-like TNCs). Most users select the return key, <cr>. This causes a packet to be sent each time you hit <cr> as you type. A second way is to specify a maximum length for a packet (PACLEN). The best length to pick depends on several factors—the mode (HF, VHF, OSCAR 10), the number of digipeaters you're using, the load on the channel, the signal strength, etc. When you have entered the specified number of characters, a packet will be sent. A third way is based on time. You can tell your TNC to send a packet every "n" seconds or after you have stopped typing for "n" seconds. You can use these three methods in any combination on most TNCs.

The end effect is that you just type on your keyboard, and the TNC takes care of sending the packets. Because of the packet-

ization process, there is always an occasional gap in your transmissions on the air. During these gaps, packets from the other station can be received. You can choose to see characters from the other station as soon as they are received, although most people use the FLOW ON command to get the TNC to hold characters from the other station until you have entered a complete line. What you then see on the screen are lines that you have entered interspersed with lines transmitted from the other station.

At least one TNC automatically performs a split-screen function. This gives you maximum flexibility in how you want to conduct your conversations. You can still talk in a paragraph mode, in which you finish a complete thought before the other station begins to respond. Or, you can rapidly trade short comments without having to make sure that the other station has dropped its carrier before you turn yours on and without having to use procedural signals such as OVER, K, AR, BK, or SO HW CPY OM. The TNC is taking care of that automatically. Full break-in RTTY is a joy to operate. We've all sat helplessly as a three-minute 60-wpm transmission has come in, answering a question we didn't ask. Packet gives you the opportunity to say, "Wait, you misunderstood the question."

A second benefit of packetization is more positive control over computer bulletin board systems (BBS). If you're an active RTTY mailbox user, how many times have you accidentally initiated a far longer dump from a mailbox than you intended? RTTY mailboxes can't hear while they're transmitting. A packet BBS can, once every 128 characters or so. You can write RTTY software that will turn off the transmitter and listen for a "go ahead" command, but that takes more software and will slow down someone who is getting what he asked for.

The third benefit of packetization I'll discuss this month is channel sharing. Digital devices can send characters faster than most hams can type. Whether you're sending on RTTY at 60 to 100 wpm or on packet at 360, 1,440, or more wpm, you can't keep the pipe full by hand, and sooner or later your type-ahead buffer runs dry. On RTTY and AMTOR, dead space between entered characters is filled with idles, diddles, or straight tone. The frequency is "in use" even though no useful information is being sent. If your typing speed is 30 wpm and the channel speed is 60 wpm, 50% of the channel time is being wasted.

On packet, all characters are queued up in the TNC until a packet is sent. Only then does your station go on the air. If your typing speed is 30 wpm and the channel speed is 1,440 wpm, your station will only be on the air 2% of the time, or actually closer to 4% counting overhead. This leaves 96% of the channel free for other conversations, even though you are "using the frequency." Thus, there is room for 24 other 30-wpm typists on the same channel at the same time. Federal law requires me to tell you that, just as with EPA mileage, your rates may differ. The mechanics of sharing the channel tend to eat up some of the time. Future columns will discuss this matter in detail. To answer the first question that always comes up when channel sharing is discussed, your TNC takes care of showing you only those packets being sent to you. But yes, you can choose to see packets that aren't directed at you (reading the mail), and yes, there is a way to send CO.

So, there we have three things packet provides that have nothing to do with linked digipeaters or error-free communications. I'll name a few more and save detailed discussion for future months.

Packet uses the full 8-bit ASCII character set. That means you can use all of the special characters, as well as lowercase. This tends to make conversations more expressive, since shouting is usually done in uppercase, LIKE THIS. As a more practical matter, it also makes connecting computers to radio easier, since you don't have to worry about mapping a 7- or 8-bit code set to a 5-bit one. You can use the control-C character to abort a message in progress on BBS systems, for instance. It is easy to connect other computer-based devices to packet, such as SSTV converters, because the TNC is taking care of all of the communications aspects.

Packetization makes nondirected round-tables possible. That's where everyone on the channel talks to everybody all at once, as in a Dayton hospitality suite. A duplex packet repeater is used for that purpose out here, and until you've actually taken part in a 28-way simultaneous conversation, you won't understand why you'd want to.

One last thing for this month that packet provides: fun. As I was writing this, Utah hams were putting up a new digipeater or two so that it was possible to get to Salt Lake City from southern California. One of the southern California packeteers, AA6TN, was having such a good time he didn't know which to do, work Utah or contact other local hams to let them know what was happening. He used packet to Utah with one hand and passed the news on a local voice repeater with the other. Although an eight-digipeater path is tenuous, it does establish future networking sites. The hard part of a nationwide VHF network is getting all the antennas, radio, TNCs, and Forest Service permits in place. Once the hardware is running, software improvements like those announced at the Orlando conference in March will provide the solid performance that packet promises.

Orlando

The 5th Amateur Radio Computer Networking Conference, sponsored by the ARRL, was held in Orlando, Florida in March. These conferences attract hams from all over North America and abroad to discuss packet radio issues and plan for the future. They are scheduled at roughly one-year intervals and usually trade coasts each year. During the conference, there were several demonstrations of software that will provide the next level of network linking. These "smart digipeaters" will spring up like wildfire as soon as final testing is complete. As is usual, there is more than one way to skin a cat. Two different methods of networking were shown, and each method had a camp of loyal followers. The whole topic of networking will be discussed in an article in the August issue of *73*, so reserve your copy now. The technical papers that were presented at the conference have been bound and published by the ARRL and are available from the League, as are the Proceedings of the 5th Networking Conference.

Up To Date News

Due to the publication delays in large magazines, you won't see many news-breaking items here first. I'll try to provide background and commentary for major news items, though. The job of this column is to take a more leisurely look at things, to answer your questions, and to fill in the gaps. There are several excellent ways to keep track of the fast-moving world of packet as things happen, however.

The best way is to take the plunge and get on packet. Even if you primarily want to ragchew, the various BBS systems in your area carry the latest news. One of the newsletters you usually find on packet BBS systems is the *GATEWAY* newsletter. The ARRL publishes this newsletter every two weeks and permits the reproduction and dissemination of the information on packet systems. The newsletter is also available by subscription. If you do read it on a packet system, please drop them a line to let them know so they can continue to justify the expense of releasing it "for free." Another way to get current information is via CompuServe's HAMNET. This will cost you some bucks, but most of the news and technical information finds its way to HAMNET sooner or later. I'm on HAMNET, and so are the Funl and RTTY Loop columnists and the *73* Editor, but don't let that dissuade you.

For international packet users, as well as local folks, the UoSat-OSCAR-9 and UoSat-OSCAR-11 spacecraft carry plain-text ASCII bulletins that include major packet news. A future column will contain information on how to copy the digital satellites. I have at least a year's backlog of things to talk about, so I hope no one catches me having a good time and shuts me down before then. The AMSAT publications provide satellite information. Ask an AMSAT member for a peek at his back issues, or better yet, become a member yourself. There will be two packet-related amateur satellite launches this year.

That's all for this month, next month I'll discuss FCC RM 85-105, the automatic control order, plans for an STA request for automatic control of HF store-and-forward message systems, and the Dayton packet activities. Until then, see you on packet. ■

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial offices, 73 Magazine, WGE Center, Peterborough, NH 03458-1194.

PICCOLO SPOLETO FESTIVAL
MAY 24–JUN 7

The Trident ARC will operate N4EE to commemorate the Piccolo Spoleto Festival's ninth season of presenting local and southeastern regional talent from every artistic discipline, as follows: 1400 UTC to 2400 UTC on May 24–25, May 31–June 1, and June 7. SSB—7.249, 14.240, 21.340, and 28.540; CW—7.120 and 21.120. Certificate for QSL and large SASE to TARA, PO Box 73, Summerville SC 29484–0073.

BLOSVALE NY
JUN 1

The Rome (New York) Radio Club, Inc., will sponsor its 34th annual Ham Family Day on June 1, beginning at 9 a.m., at Becks Grove, Blosvale, New York. Talk-in on 146.28/.88 and 146.34/.94. For more information or for reservations, write the Rome Radio Club, Inc., Box 721, Rome NY 13440, or call William Effland at (315)-853-5700.

HUMBOLDT TN
JUN 1

The Humboldt ARC will sponsor its annual hamfest on Sunday, June 1, at Bailey Park, 22nd Avenue, Humboldt, from 8 a.m. to 4 p.m. Admission is $1. Talk-in on .37/.97. For further information, contact Ed Holmes W4IGW, 501 N. 18th Avenue, Humboldt TN 38343.

CHELSEA MI
JUN 1

The Chelsea Communications Club will sponsor its ninth annual Swap 'N' Shop on June 1, from 8 a.m. to 2 p.m., at the Chelsea Fairgrounds, Chelsea, Michigan. Admission is $2.50 in advance and $3 at the door. YLs, XYLs, and kids under 12 are free. Table space (8 feet) is $8; trunk sale space is $2. Talk-in on 147.255. For more information, call (517)-764-5785, or write William Altenberndt, 3132 Timberline, Jackson MI 49201.

MILESTONES OF MEMORIES
JUN 6–8

The Wichita (Kansas) ARC will operate special-event station WØ SOE from Lewis, Kansas, on June 6–8 to help celebrate its centennial. The Milestones of Memories operation will be on approximately 3.875, 7.250, 14.250, and 21.325 MHz. QSL via WØSOE, Wichita ARC, 707 N. Main, Wichita KS 67203.

LIGHTSHIP PORTSMOUTH
JUN 6–8

The Portsmouth (Virginia) ARC will operate W4POX on June 6–8, 1500–0800 UTC daily, from the Lightship Portsmouth at the Portsmouth Seawall Festival. Frequencies are 7.230 and 14.290. For a commemorative QSL, send a QSL and an SASE to W4POX, 4800 Manor Avenue, Portsmouth VA 23703. For a QSL and a certificate, send your card and a 9 x 12 envelope with 44 cents postage.

GUELPH ONT
JUN 7

The Kitchener-Waterloo ARC will sponsor the 12th annual Central Ontario Amateur Radio Flea Market and Computerfest on Saturday, June 7, from 8 a.m. to 2 p.m., at the Col. John McRae Legion Hall, Guelph, Ontario. Admission is $2. Inside space is $8 (table included). Outside space is $3. Talk-in on 147.960/.360 and .52. For more information, write the Kitchener-Waterloo ARC, PO Box 812, Kitchener, Ontario, Canada N2J 4C2, or call Paul VE3CHM at (519)-579-3057.

NORTH GEORGIA
JUN 7

The John Ross ARC will sponsor the fourth annual North Georgia Hamfest on Saturday, June 7, beginning at 8 a.m., at Lakeview Fort Oglethorpe High School, five miles south of Chattanooga, Tennessee. Admission is $1; flea-market spaces are $6; tailgating spaces are $2. Exams will be given. For more information, write the John Ross ARC, PO Box 853, Rossville GA 30741, or call Murel Winans KA4LMG at (404)-867-7739.

ST. PAUL MN
JUN 7–8

The North Area Repeater Association will sponsor its Amateur Fair on the weekend of June 7 and 8 at the Minnesota State Fairgrounds in St. Paul, Minnesota. Admission is $4 in advance or $5 at the Fair. Amateur license exams will be given. Giant outdoor flea market, exhibits, commercial dealers. Free overnight parking June 6 and 7 for self-contained campers. Talk-in on .25/.85 or .16/.76 repeaters. For dealer inquiries, tickets, and further information, write Amateur Fair, PO Box 857, Hopkins MN 55343, or call (612)-566-4000.

OHIO WINE MONTH
JUN 7–8

WINO (Wireless Institute of Northern Ohio), an organization sponsored by the Lake County Amateur Radio Association, will be on the air from a winery in Madison, Ohio, with the call KO8O, to commemorate Ohio Wine Month. Operation will be on 3.860 and 7.235 from 2300 UTC to 0300 UTC, Saturday, June 7, and on 7.235 and 14.235 from 1500 UTC to 1900 UTC on Sunday. For a special 8-1/2 x 11 certificate, send a legal-size SASE to KO8O WINO Weekend, 7126 Andover Drive, Mentor OH 44060.

25TH ANNIVERSARY
FAIR LAWN NJ ARC
JUN 7–8

The Fair Lawn ARC will operate the club station under founding member Frank Leonard's call, W2NPT, to commemorate the 25th anniversary of the club. Operation will be from 1300 to 2200 UTC on the 7th and from 1400 to 1500 UTC on the 8th. Frequencies: CW—7.050, 7.110, 14.050, and 21.050 (±10 kHz); phone—7.285, 14.285, and 21.385 (±10 kHz). For a certificate, send a QSL and an SASE to Frank Leonard W2NPT, 17–12 Well Drive, Fair Lawn NJ 07410.

LOVELAND CO
JUN 7–8

The Northern Colorado ARC will sponsor Superfest VIII on June 7–8, beginning at 9 a.m., at the Larimer County Fairgrounds, Loveland, Colorado. Admission is $3; tables are $5; tailgating is $5. For more information, contact Cliff Baker WØITD, 2623 52nd Avenue, Greeley CO 80634; (303)-330-3548.

ERLANGER KY
JUN 7–8

The Northern Kentucky ARC will sponsor Ham-O-Rama '86 on June 7–8, beginning at 8 a.m., at the Best Western Vegas Convention Center, Erlanger, Kentucky. Admission for both days is $5; children under 13 are free. Indoor and outdoor flea market—contact AF4Y or WD4PBF at the gate for spaces and prices. Talk-in on 147.855/.255. For more information, call Joe Dunnett WA4WNF at (606)-371-2255 or write NKARC at PO Box 1062, Covington KY 41012.

SJRA 70TH
JUN 7–16

The South Jersey Radio Association, the oldest radio club in the U.S., will operate special-event station K2AA from 1200 UTC on June 7 until 1200 UTC on June 16 in celebration of the club's 70th birthday. Frequencies: phone—3.890, 7.240, 14.280, 21.360, 28.600; CW—3.590, 7.050, 14.050, 21.090, 28.150; two meters; Novice bands. For a commemorative QSL, send an SASE and a QSL (or log Info) to the South Jersey Radio Association, PO Box 1026, Haddonfield NJ 08033.

LEWISBURG PA
JUN 8

The Milton ARC will hold its 12th annual hamfest on Sunday, June 8, from 8 a.m. to 4 p.m., at the Winfield Firemen's Fairground, four miles south of Lewisburg, Pennsylvania. Admission is $3; women and children are free. Talk-in on 146.37/.97 or 146.025/.625. For more information, contact Jerry Williamson WA3SXQ, 10 Old Farm Lane, Milton PA 17847; (717)-742-3027.

ROANOKE VOYAGES
JUN 8, 10

The Raleigh Amateur Society, in conjunction with the hams of North Carolina and in cooperation with the North Carolina State Department of Cultural Resources, will celebrate the 400th anniversary of Sir Walter Raleigh's Roanoke Voyages by operating special-event station W4DW. Operation will be on 3.905, 7.250,

and 14.335 MHz (±QRM) from 1500 to 2100 UTC on both Sunday, June 8, and Tuesday, June 10. For a commemorative QSL card and historic literature, send your QSL card and a #10 SASE to W4DW RARS, PO Box 17124, Raleigh NC 27619. Your card and our logs will become a permanent part of the log of *Elizabeth II*, a sailing replica of the original craft.

QUEENS NY
JUN 8

The Hall of Science ARC will sponsor a hamfest on June 8, from 9 a.m. to 4 p.m., at the Hall of Science Parking Lot, Flushing Meadow Park, 47-01 111th Street, Corona, Queens, New York. Admission is $3 for buyers; $5 for sellers. Talk-in on 144.300 simplex link, 223.600 repeat, and 445.225 repeat. For more information, call John Powers KA2AHJ at (718)-847-8007, or Arnie Schiffman WB2YXB at (718)-343-0172.

GRANITE CITY IL
JUN 8

The Egyptian Radio Club will hold its 57th annual hamfest on Sunday, June 8, from 8 a.m. to 3 p.m., at the ERC clubhouse and grounds. Admission is $1 in advance; $2 at the door. The first flea-market space is free; each additional space is $5. Directions: I-270 to IL Route 3 South, turn right at Chain of Rocks Road, then follow signs. Talk-in on 146.16/.76 or 146.52. For tickets or more information, send an SASE to the Egyptian Radio Club, PO Box 562, Granite City IL 62040.

DREXEL HILL PA
JUN 8

The Delaware County ARA will sponsor its seventh annual hamfest on June 8, beginning at 8 a.m., at the Drexel Hill Middle School, Drexel Hill PA. Admission is $3. Indoor tables with power are $3; outside tailgating is free. Exams will be given. Talk-in on 147.96/.36, 224.5, and 146.52. For more information, write to Hamfest, DCARA, PO Box 236, Springfield PA 19064, or call Barbara N3DLG at (215)-535-1616.

NEWINGTON CT
JUN 8

The Newington ARL will hold its third annual flea market on Sunday, June 8, from 9 a.m. to 2 p.m., at Newington High School, Willard Avenue (Route 173), Newington, Connecticut. Admission is $2. Tables are $10; tailgating is $5. Talk-in on 146.52, 144.85/145.45, and 223.24/224.84. For more information, send an SASE to Les Andrew KA1KRP, 23 Grove Street, West Hartford CT 06110; (203)-523-0453.

WRIGHTSTOWN PA
JUN 8

The Warminster ARC will sponsor its 12th annual hamfest on Sunday, June 8, beginning at 7 a.m., at the Middletown Grange Fairgrounds, Penns Park Road, Wrightstown, Pennsylvania. Admission is $3; XYLs and children are free. Outdoor tailgating spaces are $5; indoor spaces with 8-foot table and power are $5 (pre-registration suggested). Talk-in on 147.69/.09 and 146.52. For information or pre-registration, contact Chuck Dunn KA3FQQ, 1414 Bradley Lane, Warminster PA 18974; (215)674-8567.

LOUSIVILLE KY
JUN 11–14

The Antique Radio Club of America will hold its annual national convention on June 11–14 in Louisville, Kentucky. All interested people are invited. ARCA has about 1000 members who collect and restore antique wireless and radio equipment and who study and record the history of early radio. For more information on the convention or ARCA membership, contact ARCA, 81 Steeplechase Road, Devon PA 19333; (215)-688-2976.

CORTLAND NY
JUN 14

The Skyline ARC will sponsor a hamfest and flea market on Saturday, June 14, from 8 a.m. to 5 p.m., at the Cortland County Fairgrounds, Cortland, New York. Admission is $3; under 12 free. Outdoor flea-market space is $1; an indoor table is $5. For more information, call Billy N2AGF at (607)-749-3766, or Bud K2ZER at (607)-753-3994.

BSA SCOUT-O-RAMA
JUN 14

The Chicago Suburban Radio Association will operate its third annual special-event amateur-radio station, N9BAT, from the Brookfield Zoo, Brookfield, Illinois, on June 14, from 1500 to 2300 UTC, as part of the West Suburban Council, BSA, annual Scout-O-Rama. Frequencies: 7.250 and 14.250 MHz. A special full-color QSL card available for a QSL card and business-size SASE to N9BAT Special Event, PO Box 88, Lyons IL 60534.

TWIN FALLS ID
JUN 14–15

The Magic Valley Chapter of the Idaho Society of Radio Amateurs will sponsor a swap meet on June 14–15, from 10 a.m. to 5 p.m. on Saturday and from 8 a.m. to 12 noon on Sunday, at the Moose Lodge, 835 Falls Avenue, Twin Falls, Idaho. Admission is free. Talk-in on 146.16/.76. For more information, write the Idaho Society of Radio Amateurs, Magic Valley Chapter, PO Box 294, Twin Falls ID 83303.

CROWN POINT IN
JUN 15

The Lake County ARC will sponsor its 14th annual Fathers' Day Hamfest on Sunday, June 15, from 8 a.m. to 2 p.m., at the Lake County Fairgrounds Industrial Building, Crown Point, Indiana. Admission is $3. Tables will be available. Talk-in on 147.84/.24 or 146.52. For more information, write Bill DeGeer W9TY, 3601 Tyler Street, Gary IN 46408, or call (219)-887-5413 after 6 p.m.

FREDERICK MD
JUN 15

The Frederick ARC will hold its 9th annual hamfest on June 15, from 8 a.m. to 4 p.m., at the Frederick Fairgrounds, Frederick, Maryland. (Gates open for ex-

SATELLITES

USING THE A0-10 PREDICTIONS

Apogee predictions for the month of June are provided for three sections of the United States: Washington, D.C.; Denver, Colorado; and Los Angeles, California. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

hibitors at 8 p.m. on the 14th. Overnight security and parking provided.) Admission is $3, tailgaters $2 additional; exhibitor tables are $10 for the first, $5 for each additional table. YLs and children admitted free. For additional information, write Jim Kasunic KA3LPC, 9419 Highlander Court, Walkersville MD 21793.

DUNELLEN NJ
JUN 21

The Raritan Valley Radio Club will hold its 15th annual hamfest on Saturday, June 21, beginning at 8 a.m., at Columbia Park, Dunellen, New Jersey. Admission is $3; spouses and children are free. One selling space is $5; $10 for multiple spaces. Tables are not supplied. Talk-in on 146.025/.625 and 146.52. For more information, call Dave KA2TSM at (201)-763-4849 or Bill N2AZX at (201) 467-7342.

ARGONNE LAB
JUN 21

The Argonne ARC will operate special-event station W9QVE from 11 a.m. to 4 p.m. CST on June 21 to commemorate the 40th anniversary of the establishment of the U.S. National Laboratory System (Argonne was the first). Operation will be on 144.59/145.19 and the phone portion of the 20-meter General band. Send a QSL and an SASE to AARC, PO Box 275, Argonne IL 60439.

MANCHESTER NH
JUN 21

The New Hampshire FM Association will sponsor an amateur radio/electronics flea market on Saturday, June 21, beginning at 9 a.m., at the Manchester Municipal Airport, Manchester, New Hampshire. The rain date is Sunday, June 22. Admission is $1; $5 for sellers—tables not provided. Talk-in on 146.52 FM. For more information, contact Pete Henriksen WA1RCF, 123 Woodlawn Circle, Portsmouth NH 03801; (603)-431-5432—or call Doug Aiken K1WPM at (603)-622-0831.

TWIN VALLEY 100TH
JUN 27–30

Special-event station KE0DJ will be operated on June 27–30 to commemorate the centennial of Twin Valley, Minnesota. Operation will be primarily on 15, 20, and 40 phone, as well as available satellites. QSL with #10 SASE to KE0DJ, c/o Dale Cary WD0AKO, 1318 34th Avenue S. #301, Moorhead MN 56560.

GRAND RAPIDS MI
JUN 28

The Independent Repeater Association will sponsor its annual IRA Hamfest, "The Amateur Extravaganza," on June 28, from 8 a.m. to 4 p.m., at the 44th Street Armory, Grand Rapids. Admission is $3.50; tables free. Take U.S. 131 south of Grand Rapids to 44th Street and go west 1 mile. Talk-in on 147.765/.165. For table reservations and further information, write the Independent Repeater Association, 562 92nd Street, Byron Center MI 49315, or call Abe W8HVG at (616)-455-3915.

LINCOLN BIRTHPLACE
JUN 28–29

The Lincoln Trail ARC will operate special-event station W4BEJ from the Abraham Lincoln Birthplace National Historic Site near Hodgenville, Kentucky, during Field Day, June 28–29. For a commemorative certificate, send a QSL and an SASE (Note: LTARC log will show only Field Day calls—be sure that you include that information) to LTARC, PO Box 342, Vine Grove KY 40175.

VANCOUVER 100TH/
VARC 50TH
JUN 28–29

The Vancouver ARC is celebrating its home city's centennial and its own 50th anniversary by operating two Field Day stations on June 28–29. In cooperation with the Expo '86 Amateur Radio Committee, the club will operate station VE7 EXPO and station VC 100. Those who contact either station will receive a special QSL.

ACB 50TH
JUN 29–JUL 5

The ACB Radio Amateurs, a special-interest affiliate of the American Council of the Blind, will operate special-event station KW4U from 0000 UTC on June 29 until 2400 UTC on July 5 from the Hilton Hotel in Nashville TN, the sight of the ACB's silver anniversary convention. Operation will be 80 through 10 meters: 30 kHz from the bottom of CW bands; 5 kHz from the bottom of phone bands (±QRM). For a commemorative certificate, send a QSL to John McCann K4WU, 2105 W. Illinois Street, Arlington VA 22205.

FEEDBACK

In our continuing effort to present the best in amateur radio features and columns, we've decided to go directly to the source—you, the reader. Below, the articles and columns in this issue are assigned numbers. These numbers correspond to those on the "Feedback" card opposite this page. On the card, please check the box which honestly represents your opinion of each article or column.

"What's in it for me?" comes the cry from our faithful readers. Besides the knowledge that you're helping us find out what you like (and don't like), we'll draw one Feedback card each month and award the lucky winner a free one-year subscription (or extension) to *73*.

To save some money on stamps, why not fill out the Reader Service card, the Product Report card, and the Feedback card and put them in an envelope. Toss in a damning or praising letter to the editor while you're at it. You can also enter your QSL in our QSL of the Month contest. All for the low, low price of 22 cents!

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

THE SIXTH TIME AROUND

Is the Fun! Poll an institution or does its supervisor just belong in one?

Let's see—in ham radio three qualifications are required before something can be considered an institution. Most important, you have to be old. Well, I'm 31 and the poll is six. That's not old, it's just "getting there."

Next, ham institutions have to be serious. I guess we flunk there, too. After all, how can you take anything called a Fun! Poll seriously?

Finally, to be an amateur radio institution you have to be outdated. We can't qualify under that category either, since more people notice the poll and respond to it every year.

So there you have it: The Fun! Poll is definitely not an institution. That's this year's first conclusion.

As usual, we had a lot of fun tabulating the results. This year, computers helped us in a big way: two Apple IIe's and an Apple IIc, plus a 20-megabyte hard-disk drive enabled us to handle the calculations. That's a lot of computing power for a non-institution.

I'd also like to thank WB2LWJ for entering all of that data and downloading the responses from CompuServe, The Source, and MCI Mail.

The envelopes, please...

ELEMENT 1
BACKGROUND

1) Sex:
A) Male—98%
B) Female—2%
Ham radio, like Mars in that old B-movie, needs women.

2) Age:
A) 15 or below—2%
B) 16–21—0%
C) 22–39—42%
D) 40–59—40%
E) 60 or above—16%
The graying of amateur radio. The kids are gone!

3) License class:
A) Novice—4%
B) Technician—10%
C) General—8%
D) Advanced—46%
E) Extra—32%
Fun! obviously attracts a very educated audience.

4) Number of years licensed:
A) 1 year or less—8%
B) 1–5 years—16%
C) 6–10 years—28%
D) 11–20 years—8%
E) 21 years and up—40%
A veteran crowd, indeed.

5) Do you have a new (post-March '78) call?
A) Yes—56%
B) No—44%
Next year, we'll have to ask, "Do you have an old (pre-March '78) call?"

6) How many hours a week do you devote to amateur radio?
A) 0–1 hour—20%
B) 2–5 hours—36%
C) 6–10 hours—22%
D) 11–20 hours—16%
E) 21 hours or more—6%
That's a fair amount of activity.

7) Which HF band do you use most?
A) 80–75 meters—30%
B) 40 meters—18%
C) 20 meters—26%
D) 15 and/or 10 meters—12%
E) Don't operate HF—14%
Who says the low bands are obsolete?

8) Which VHF/UHF band do you use most?
A) 6 meters—2%
B) 2 meters—64%
C) 220 MHz—8%
D) 420 MHz and/or up—6%
E) Don't operate VHF/UHF—20%
Hey, guys! Spread out!

9) Which mode do you use most?
A) SSB—44%
B) CW—26%
C) FM—24%
D) RTTY—2%
E) Other—4%
CW holds its own.

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenses.)
A) 0–$250—42%
B) $251–$500—20%
C) $501–$1,000—18%
D) $1,001–$2,500—12%
E) $2,501 and up—8%
Compared to many other hobbies, that's not a heck of a lot of money spent.

ELEMENT 2
SOCIAL CHARACTERISTICS

11) On the whole, hams are:
A) too young—0%
B) too old—58%
C) just the right age—42%
At least the age problem is getting some recognition.

12) Do you like rock music?
A) Yes—54%
B) No—46%
Not Lawrence Welk? Not on 2 meters?

13) Politically, how would you define yourself?
A) Conservative—52%
B) Middle-of-the-road—30%
C) Liberal—18%
K7UGA must be happy.

14) Should we get rid of the ARRL?
A) Yes—10%
B) No—90%
I guess that puts me in the minority. I'm for attacking Newington with a rettysnitch.

15) How old were you when you first became a ham?
A) 15 or below—26%
B) 16–21—28%
C) 22–39—32%
D) 40–59—12%
E) 60 or above—2%
See Question 2 and groan.

16) Should the FCC increase the speeds on amateur CW examinations?
A) Yes—6%
B) No—94%
How about increasing the speed on the written exam? Give those VEs a break.

17) Do you own a home computer?
A) Yes—74%
B) No—26%
I'd like to meet the hams who don't own one. Probably don't even use a digital display, heaven forbid.

18) If you answered "yes" to question 17, which brand?
A) Apple—20%
B) IBM—14%
C) Radio Shack—12%
D) Commodore—34%
E) Other—20%
Imagine if these figures reflected the computer market as a whole. Golly.

19) Do you think that home computing is siphoning people (including youngsters) away from amateur radio?
A) Yes—62%
B) No—38%
Those kids have to be doing something.

20) Are hams getting dumber?
A) Yes—42%
B) No—58%
Could have fooled us.

21) Do business interests deserve some of our virtually abandoned bands?
A) Yes—10%
B) No—90%
Use it or lose it, I say.

22) Should ham licenses have a minimum age requirement?
A) Yes—12%
B) No—88%
We have a de facto one anyway, right?

23) Should ham licenses have a maximum age requirement?

A) Yes—4%
B) No—96%
How about 100 years old as a limit, or would that eliminate too many hams? Only kidding, guys.

24) Should hams be subject to periodic retesting?
A) Yes—30%
B) No—70%
Why not? Could be fun. Imagine the ARRL board of directors flunking.

ELEMENT 3
OPERATING HABITS

25) If the users were restricted to data communication only (no phone or CW operation), would you be in favor of a no-code 220-MHz digital-class license?
A) Yes—74%
B) No—26%
What happened? A few years ago we would have been clobbered for even asking this question.

26) Would you be in favor of a no-code 220-MHz digital-class ticket if it permitted phone operation in addition to data transmission?
A) Yes—52%
B) No—48%
Ditto.

27) Have you ever used a personal computer in connection with your amateur radio activities?
A) Yes—66%
B) No—34%
Down 6 percent from last year.

28) Is it time to completely deregulate amateur radio by having the FCC turn over all responsibility for ham operation to the amateur community?
A) Yes—16%
B) No—84%
Moderation, moderation!

29) What do you think of people who view pay television services with MDS converters and satellite dishes that are not approved by broadcasters?
A) They're skunks—2%
B) They're within their rights—98%
As a dish owner, I agree.

30) Should we get rid of, or reduce in size, the CW subbands?
A) Yes—28%
B) No—72%
Let's rename them as "data bands."

31) Do you think DX nets have a place in ham radio?
A) Yes—76%
B) No—24%
A small place, I think.

32) Do you think nets in general have a place in ham radio?
A) Yes—88%
B) No—12%
As long as they're not DX nets.

33) The next time a ham operates from space, which band should he/she use?
A) 2 meters—52%
B) 220 MHz—14%
C) 450 MHz—14%
D) An even higher band—6%
E) Shouldn't bother to operate—14%
How about 160 meters? They'd have to carry the antenna on another orbiter.

34) If, while tuning across a band, you heard a net called "Jammers International" in progress, would you:
A) Jam it—2%
B) Ignore it—48%
C) Complain to the FCC or some other organization—18%
D) Listen—26%
E) Join it—6%
Hams are getting mellower in their old age.

35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes—62%
B) No—38%
Sure, and all aspirins are alike.

36) If required, could you pass the FCC theory test for your license class?
A) Yes—88%
B) No—12%
But didn't Dick Bash go out of business?

37) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes—4%
B) No—96%
Oops, the dial slipped.

38) Are you fluent in any computer language?
A) Yes—66%
B) No—34%
Of course everyone probably has his own definition of "fluent."

39) If you answered "yes" to Question 38, which language?
A) Basic—50%
B) Pascal—8%
C) Assembler—10%
D) Machine—10%
E) Other—22%
Basic wins again, but the other languages are gaining strength.

40) Do you feel competent to write a short Basic program?
A) Yes—72%
B) No—28%
10 PRINT "Hello"

41) Do you feel competent to replace the finals in a transistor-type rig?
A) Yes—92%
B) No—8%
Without killing yourself? Gee.

42) Do you solder together your own coax connectors?
A) Yes—100%
B) No—0%
What? Nobody uses solderless connectors?

43) Do you own a TVRO (home Earth satellite) system?
A) Yes—10%
B) No—90%
And HBO sees a market here?

44) Do you operate a packet-radio system?
A) Yes—12%
B) No—88%
This will be a question to watch in the future.

45) What do you think of contesting?
A) Great—10%
B) Good—18%
C) Okay—46%
D) Don't like it—14%
E) Despise it—12%
Sorry, WB2GFE.

46) What do you think of DXing?
A) Great—26%
B) Good—44%
C) Okay—26%
D) Don't like it—2%
E) Despise it—2%
A general vote of approval.

47) What do you think of repeaters?
A) Great—32%
B) Good—44%
C) Okay—18%
D) Don't like them—2%
E) Despise them—4%
But what do you think of the people on repeaters?

48) What do you think of traffic handling?
A) Great—10%
B) Good—48%
C) Okay—26%
D) Don't like it—10%
E) Despise it—6%
What's not to like? I mean, some people think exercise is fun.

49) If you heard an emergency net in progress, would you immediately join in and offer your services?
A) Yes—54%
B) No—46%
Little gold stars to the respondents who said they would join in only if they had traffic to pass.

50) Have you ever secretly hoped for a minor disaster to strike your community just so you could demonstrate your radio skills?
A) Yes—14%
B) No—86%
Regardless of the numbers, I still think most hams really do hope for trouble.

WA6ITF RETURNS

This column was originally written for publication in the January, 1982, issue of this magazine. The column was canceled by the decision to reformat 73, but I felt that I had an obligation to "...finish what I had started before going on." Next month, a look at what's happening today, with an emphasis on the emergence of regional band-planning super-councils.—WA6ITF.

I've often addressed the question of band-plan standardization in this column, not just with regard to the FM relay mode, but for all types of operation. This is because it is my strong belief that only through such standardization can every mode, special interest, and amateur be assured of spectrum to "do his own thing" on our crowded VHF (and now UHF) bands.

Over the years, I have put forth ideas on how such standardization could be accomplished, presented complete conceptual band plans, and what have you. It's interesting to note that some 15 years after the start of the VHF FM explosion only one of our amateur bands—220 to 225 MHz—has a band plan accepted on a national scale, including Southern California. As you are aware, the latter has been known to go its own way in most cases, caring little what the rest of the country is up to. Witness the decision back in '77 to use the "even-numbered" channel pairs in the 144.5–145.5-MHz repeater subband—every-

where else it's the "odd numbers" that are used. Some say that Southern California can't do anything right, but the hams of this area tend to consider themselves the true trend-setters; eventually "everyone else" will notice the error of his ways and come to this geographic locality's way of thinking.

In some cases it has happened. Inverted split-splits on 2 meters from 146 to 148 MHz were commonplace throughout half the nation until 20 kHz came along; the concept of inverting the tertiary channels was spawned by two well known Southern California hams, Burt Weiner K60QK and Bob Thornburg WB6JPI. This is common knowledge. At the time it also seemed to be a rather good alternative to the problems inherent with non-inverted 15-kHz tertiary channels. Like everything else in life, there was a trade-off involved. With non-inverted 15-kHz tertiaries, adjacent-channel repeaters can interfere with users. When you invert the 15-kHz channels, the user's radio sees a "30-kHz clear slot" for the most part, but now repeaters can interfere with other repeaters. This is because the output of Repeater A is only 15 kHz from the input to Repeater B. Obviously, where the terrain provides for geographic shielding and/or system separation, this is no problem. In cases where it doesn't, then some elaborate equipment is necessary to make the concept play. This may include such items as specially designed receivers with high dynamic range figures, suck-out traps and cavities, circulators, and the like. The system does work, as has been proven here and elsewhere for the better part of 12-1/2 years now, but at best, it's still a trade-off—in this case protecting the "user's radio" at the expense of overall repeater system performance.

Many years ago, an amateur in the Northeast named George Le Dioux K1TKJ came up with an even better solution. This was back in the late 1960s, FM's formative era. George suggested two changes that would have avoided the many pitfalls we've faced and had to find ways around. K1TKJ's idea was to put all two-meter repeaters on 20-kHz inter-system spacing, and utilize an input-to-output spacing of 1 MHz. Had this been done back in 1969, we would never have faced the concept of 15-kHz tertiary splits. True, there wouldn't have been as many repeater pairs available, but overall technological system operation would have been vastly improved. But this was not to be the case. Le Dioux's ideas were ignored and the nation stayed with 30-kHz inter-system spacing and 600-kHz input-to-output separation. There were a number of reasons for this, the primary one being that at the time of the K1TKJ proposal, Technician-class operators were not permitted operation in the 147–148-MHz spectrum. With most radios being crystal-controlled in that era, 147.97 was considered the ex-officio top end of the "open repeater band."

Then came repeater deregulation. Technicians were granted operating privileges in the 147-MHz region. The doctrines of "Semi-Automatic" and "Fully Automatic" remote controls were established in D.C. and the big repeater rush was on. (It should be said that two Southern California amateurs were directly responsible for this first of many deregulatory moves with regard to repeater operation. They are Capt. Dick McKay K6VGP and Fred Deeg N6FD. Without their unceasing efforts on our behalf, the deregulatory process might never have come about.) Soon we were out of 30-kHz channels. The Northeast and then the entire eastern seaboard opted, ever reluctantly, to initiate the use of 15-kHz inter-system spacing. At that time little was known with regard to 15-kHz system spacing, so the decision was made to go "standard" right-side-up configuration.

The early days were hectic. The average ham transceiver of the day had been developed in the era of 60-kHz spacing; most could hack 30 kHz with little degradation in performance, but 15 kHz was another story. The same held true for a number of years through the mid 1970s. To this day I and a bunch of friends hold the somewhat dubious honor of having placed the first non-inverted 15-kHz tertiary machine in the nation into operation. Its callsign was WA2ZWP; it was located atop the Williamsburg Bank Building in Brooklyn, New York, on a frequency pair of 146.205 in, 146.805 out. No matter what we tried, it still wreaked havoc on our two neighboring systems (.19/.79 and .25/.85). Not to the systems themselves, but to those using these two machines. Then again, they each only got it from "one side." Our users were caught smack dab between the other two systems, and it took a lot of research by our Technical Chairman, Dave Kuraner, into new filters to make most of our users' radios function on the system. In fact, Dave, Larry Levy, and I were the only three who could really make use of the system in the early days. We were the lucky ones. We were using converted Motorola and RCA landmobile radios which had the needed selectivity. Most of the others were not that fortunate. Somehow, the WA2ZWP repeater survived for a few years. It led the way for others who were intrepid enough to copy our foolishness. Soon a de facto 15-kHz standard existed in the Northeast and spread elsewhere as areas ran out of 30-kHz channel pairs. It should also be noted that in spearheading the use of 15-kHz channel pairs, the Northeast was ahead of everyone else. It would be several years before the next major FM-oriented area would make the move, and when it did it would be in a different vein. Southern California elected to invert its tertiary channels as already mentioned, and most of the country west of the Continental Divide eventually followed suit as the need arose to implement utilization of 15-kHz channel pairs.

The ARRL gave its *official* blessing to either 15-kHz plan, but most of those placing repeaters into operation in a given area have kept with the norms established for that geographic region. Oh. . .there have been a few renegades here and there, but few problems have arisen and the status quo has been maintained. But many wondered if there was a better way. Most radios sold these days do operate fairly well on even, right-side-up 15-kHz channels, though in a 30-kHz or even an inverted 15-kHz environment, their overall operation seems greatly improved. I suspect that many of you reading this were not even around in the 30-kHz days. Very few, if any, are left from the 60-kHz era, so few are familiar with the way two meters sounded back then. I won't try to reconstruct the past other than to say that in the old days repeaters were fairly silent, with most FM being simplex in nature. How things have changed.

Is there an alternative to implementing 15-kHz tertiaries when you run out of the 30-kHz-split channel pairs? What about K1TKJ's old "Let's revamp to 20-kHz and 1-MHz input-to-output spacing"? Most amateurs felt that it was too late to go this route because of the investment in established hardware—both "system" and "user" hardware. At least one geographic locality seems to have decided to buck today's trend and has opted for something akin to the old K1TKJ concept. They have instituted the use of 20-kHz inter-system spacing, but have retained the standard 600-kHz input-to-output spacing. Actually, this is not so much an adaptation of K1TKJ's ideas as it is the adoption of the NARC 144.5–145.5-MHz band plan for the upper two MHz of the band. The area in question is the Pacific Northwest, and results are reported as being very positive. So much, in fact, that now the Canadian province of British Columbia has joined with Washington, Oregon, Utah, Montana, Texas, Arizona, New Mexico, Idaho, and eastern states like Alabama and Michigan to make this more than an experiment. Rather, things have reached the point where 20-kHz inter-system spacing on both the upper and lower repeater subbands on two meters must be considered a true regional band plan.

I am not saying that we should scrap years of commitment to 30-kHz and 15-kHz operation, but what has been accomplished in the Pacific Northwest is of definite note. They did not double the number of available channel pairs, as would have been the case had they opted for one of the 15-kHz plans, and they didn't have to fight any of the 15-kHz problems. Nor did anyone have to run out and buy a new radio, either. As pointed out in the British Columbia FM Communication Association newsletter, most amateurs with crystal-controlled radios had no problem swinging their crystals to the closest of the new 20-kHz pairs. As for the older 15-kHz-based synthesized sets, the BCFMA newsletter went on to explain that these radios could either be converted back to their original 20-kHz centers, since that was the original Japanese design concept to start with, or another "mix-down" to permit 5-kHz or 10-kHz incrementation could be added. Newer synthesized radios,

the article added, were already equipped for either 10-kHz incrementation with 5-kHz offset, or were incremented in 5-kHz steps. For those units, no mods were needed at all.

A few years ago there was but one band plan for two meters. It was known as the Modified Texas Plan and it sufficed for its day. It was based upon 30-kHz intersystem spacing and was the plan first modified in the Northeast to accept upright 15-kHz tertiaries, and then in the Southwest to accept inverted tertiaries. Because of politics, all of these plans have won the "Official Approval" of the League's Board of Directors. Had the ARRL approved only one, we would not be facing a new political dilemma, that of having to choose from three band plans. There is mounting political pressure for the national implementation of the Pacific Northwest band plan. And it's not all coming from the Pacific Northwest, either. This reporter feels that it may be a bit too late to find a "true national standard," much less get everyone to agree on its implementation and use. It could happen, but I, for one, have stopped holding my breath.

The SCRRBA Report: Part III

We now begin the third and final installment of the SCRRBA report on the future of voluntary UHF coordination. While this report was primarily prepared for consumption in the Southern California area, it holds importance for all areas and all spectra where coordination is scarce. How to solve things? Here's one group's opinion:

Keeping Current

One of the easiest ways in which the owner of a coordinated system can aid the Technical Committee is by remaining in close contact with us. Many coordinations were performed over five years ago. Having experienced no difficulties in the operation of their machines on the coordinated channels, the owners of these machines have not kept current with our Technical Committee. Since we are constantly referring to the file cabinets which contain the collected coordination records (which contain all paperwork received by the committee regarding each system), it becomes readily apparent how old some of these files are.

In the United States the average household changes living quarters about once every five years; in Southern California it may be more frequent. Any coordination file which has not been updated in the last five years is probably useless to the committee as a source of address and telephone information. We have an independent way of verifying this statement: Each time we mail out newsletters, we have approximately 20% returned by the Post Office marked "Addressee Unknown."

It is the responsibility of the operator of a coordinated system both to recognize the value of a UHF frequency pair in Southern California and to "protect his investment" by remaining in permanent contact with the Technical Committee. It only takes a few minutes to complete and mail a coordination update and it's an excellent "insurance policy." If you're not sure when you last updated your coordination, do it now. We can never have too much data.

Avoid Wanderlust

Earlier we discussed the problems caused by "self-coordination" of new UHF systems within the array of existing repeaters and remote bases. The Technical Committee has also had problems, on a more or less continuing basis, with a different form of self-coordination performed by operators of presently functioning UHF systems: The movement of an existing system from one location where it was coordinated to a new location where it isn't coordinated.

The committee must emphasize that the coordination of a specific UHF pair for a particular individual or group is *only* for utilization at an exact land location for coverage of a specific geographic area. Coordination of a channel pair does not imply ownership with "rights" to transport the pair anywhere around Southern California. If it is necessary for the owner to move his system to a new land location, he must apply to the committee, in writing, in advance of the move, for recoordination of that system. The committee will determine whether the system can be operated at the new location without receiving interference from or creating interference with other co-channel and/or co-site systems. Please recall that the 70-cm band is not so heavily coordinated that a small change in the operation of a single system has the potential for causing a major impact on the entire regional coordination array. It is not the intention of the committee to attempt to prevent coordinated systems from moving. If it is at all feasible for the system to operate from the proposed new location, an OK will be given quickly. Rather, it is the committee's desire to prevent unnecessary work and expense, both for itself and for the owners of the affected systems.

Expect Company

Most Southern California UHF channel pairs between 440 and 450 MHz now support more than one system, and co-sharing of pairs will have to increase in the future. Long ago the committee learned an important lesson with regard to co-sharing of channel pairs: Everyone favors the practice. . .but only in principle. In its early days, the committee would contact the holder of a coordinated channel pair and request his approval for the co-sharing of his pair with another system, located far enough away geographically that mutual system interaction would be minimal. The initial response was almost always affirmative; later the complaints would start.

The committee learned that an approval for co-sharing should be interpreted as follows: "I am certainly agreeable to sharing the channel pair, as long as I can climb into my automobile and drive a minimum of 5 hours in any direction and still not hear the other system!" Therefore, we long ago stopped asking for advance approval.

SCRRBA will continue to coordinate co-channel systems using the best fit, on a geographical co-sharing basis, between a previously coordinated system and one of several completed applications for frequency coordination. A new system will be coordinated to co-share a pair with an existing system so that minimum practical overlap occurs between the users of each system. The Technical Committee will notify owners of existing systems that a specific new co-channel system has been coordinated.

In some instances there may be an occasional overlap in coverage, as mobiles from one group find themselves in specific locations which also put them within range of the other machine. This is to be expected. To prevent unnecessary access, the committee recommends CTCSS protection for mountaintop repeaters. If necessary, full CTCSS systems can be used to protect against occasional reception of the other system's talkback.

Toward The Future

The Technical Committee should make a full and complete report to the Southern California UHF community about the current state of the coordination process and explain how little flexibility the committee has in the performance of UHF frequency coordination (and why seemingly reasonable requests cannot be fulfilled). Moreover, it is the committee's hope that the community, after gaining this information, will act with the cohesiveness necessary to protect its considerable investment of time, money, and talent.

Southern California is recognized as the national leader in amateur UHF relay-system operation. Nowhere else in the country do systems exist which rival ours in complexity, sophistication, and length of service. Whether or not we can continue to operate our systems successfully in the future depends directly upon how we, individually and collectively, value and support the community's frequency-coordination program.

Summation

What you have just read is the third part of a three-installment series on the future of voluntary relay-system coordination. It was gleaned from the June, 1981, issue of the SCRRBA newsletter. Parts 1 and 2 of this series appeared in the October and November, 1981, Looking West columns.

The entire series was condensed from a report to all Southern California UHF users from the Southern California Repeater Remote Base Association and was prepared by Gordon Schlessinger WA6LBV of the SCRRBA Technical Committee. While its initial audience was obvious, in retrospect I felt that anyone involved in putting up a repeater or helping get it coordinated could learn from what this particular group is accomplishing. Yes, it was written about the Southern California UHF repeater/remote, but there is something in it for all involved in repeaters or remotes, regardless of the band they operate on.■

PLANNING FOR GOOD FIELD DAYS TO REMEMBER

"Fascinating, frustrating, or fun, Field Days are good tests of amateurs' engineering and operating ability." This was the opening sentence in an article in the June, 1969, issue of *73* Magazine entitled "A Field Day to Remember." That article told how a group of inexperienced operators quickly planned, set up, and operated a makeshift Field Day station in the 1968 Field Day contest. It was fun and a good learning experience for those involved.

In the 17 years since then, the author of that article has participated in more than a dozen Field Day contests. In the last 10 years, he has functioned as the Field Day Coodinator for the Principia College Amateur Radio Club.

The purpose of this article is to present ideas and information gained from these experiences that could help other clubs have successful Field Day stations.

Many amateur operators consider the annual Field Day the most important amateur radio contest of the year. These operators might be called the "serious contesters." They want to work hard to make the best score possible. Each year they aim to make a better score than they did the previous year. Serious contesters are sometimes young high-speed ("hot shot") operators who can go 24 hours without sleep. Other serious contesters are older men (and sometimes women) who like to compete and can compete well in Field Day contests long after they are too old to compete in athletic sports such as football, basketball, or baseball.

Other operators are less competitive and think of Field Day as a weekend social event in which they can relax after a hard week's work and have fun with other hams. These operators could be called the "socializers." Many clubs have both serious contesters and socializers who come to Field Days. Too often, the socializers do not want to do much of the work of setting up and running a Field Day station. The serious contesters resent having to do nearly all the hard work, with little or no help from the socializers.

This article will present ideas which (hopefully) will satisfy the needs of both the serious contesters and the socializers.

If a Field Day station is powered by a gasoline engine driven ac generator, keeping the generator running for 24 hours is unpleasant work. The noise of the generator creates mental fatigue, which is not helpful to the operators.

Running a Class 1A battery-powered QRP Field Day station eliminates both the noise of the generator and the work of keeping it running. Furthermore, because of the QRP multiplier, it's easier to make a good score with a QRP Class 1A battery-powered station than with a higher powered generator-powered station. For the serious contesters, a QRP Class 1A battery-powered station will provide a better score—with less work and without the tiresome noise of a generator.

Here's Why

The Field Day rules give a multiplier of five for each contact made if the transmitter's rf output is 5 Watts or less and the station is powered by batteries. This makes it possible for QRP Class 1A battery-powered stations to make higher scores than more powerful stations using gasoline engine driven ac generators (see Table 1). A QRP Class 1A battery-powered station is ideal for a club (or other group of operators) that is relatively small (three to ten serious, competitive operators). A club may have only a small group of serious contesters, and a Class 1A battery-powered QRP station would be ideal for this group (see Table 2).

How Our Group Got Started With QRP Field Days

Using power from a gasoline engine driven generator, the Principia College Amateur Radio Club did rather poorly in the 1980 Field Day contest. During the contest, a ham drove up the road from the station and tossed an antenna up into a tree. He put his little Heathkit HW-8 on a card table and connected it to the antenna, a telegraph key, and his car battery. Then he proceeded to make contacts. Many in the club were very impressed.

In discussing the club's lack of success in the 1980 contest, one member of the group made a "radical suggestion": The club should use an HW-8 transceiver in the 1981 contest to do away with the noise and work of using a generator. The others in the club agreed. In 1981, the HW-8 station made 235 contacts and 2,650 points, the highest score the club had ever made. During the contest, WØVM and his logger started operating at 11 p.m. Saturday. Others were supposed to take over at 2 a.m. Sunday. However, because there was no generator noise, these "others" fell asleep and did not go to the station until 6 a.m. WØVM and his logger were having fun making 10 contacts per hour and so didn't mind the extra operating time.

Planning a QRP Field Day

Soon after the end of a Field Day contest, members of the group can share ideas for making the next year's Field Day better. This planning can start as early as April—or even earlier, if experimenting with antennas is a part of this work. As soon as they are available, the Field Day paper forms (summary sheet, dupe sheets, etc.) should be obtained from the American Radio Relay League, 225 Main Street, Newington CT 06111. You can study the Field Day rules that appear in the May issue of *OST*. (It might be a good idea to have a few copies of the rules handy on Field Day.)

The Field Day Site

It's important to obtain a good site for your Field Day station. The site should be on high ground and

Photo A. 1982's FD station in action.

Year	Battery-powered Station Scores	Ordinary Station Scores
1980	7015	4400
1981	7220	4828
1982	9585	5852
1983	7330	6152
1984	7900	5698
1985	9270	6544

Table 1. The scores of the top Class 1A QRP battery-powered stations compared with the top scores of the ordinary Class 1A stations for the years 1980–1985.

1980	W5VBO	3
1981	W1MJ	11
1982	N4BP	3
1983	N4BP	3
1984	K9RS	7
1985	KP4FI	6

Table 2. The number of operators of the top Class 1A QRP battery-operated stations for 1980–1985.

in the clear. Our group prefers a site with no trees or only a few trees around the edges. We have good temporary antenna supports and run the antennas north and south for good east and west coverage. Field Day stations can be located in public parks, on the grounds of schools, on farms, or on other private property. It's important to make arrangements early with the people who control the site. The site should have toilet and washroom facilities nearby. Picnic tables are also useful.

Shelter

The shelter for the station should be strong so that a storm cannot blow it down, as happened to our group in 1984. If you use an open canopy, set up a strong tent beside it into which you can move the station if a storm comes up. Trailers, campers, cottages, barns, and trucks can also house Field Day stations. For ease in operating, logging, and duping, the shelter should be big enough to include a large table with a shelf on it, which can hold antenna tuners, an swr meter, and keyers.

Having a place nearby where Field Day contestants who are not operating can rest and sleep is most helpful. This place could be an extra tent or camper, or a nearby building. People can bring their own cots, sleeping bags, and blankets.

Bonus Points

The Field Day rules provide 100 bonus points for publicity: You must submit an article to a local newspaper for publication. (Radio or television publicity for the Field Day can sometimes be obtained.) A Field Day article should tell about the purposes of Field Day and about the setting up of emergency type stations all over the United States and southern Canada. Also include in the article the name of the club (or nonclub group), the location of the Field Day station, and the dates and hours of the Field Day contest. Other information appropriate for the article is the type of station (Class 1A battery-operated in the case of a QRP station), names of the group's operators, and the fact that visitors are welcome.

Submit the Field Day article to the paper in late May or very early June so it will be printed in June before the Field Day weekend. It helps if you deliver the article in person to the editor of the paper, so you can emphasize the importance of the Field Day contest and explain that it's *the big amateur radio contest of the year*! Keep a copy of the article to send to the ARRL along with the summary sheet and other papers, in case the newspaper doesn't print the article. Proof that the article has been submitted will provide the 100 bonus points for publicity. If the article is printed, send a copy of it along with the other documents to the ARRL after the contest.

If you plan to make five contacts with "natural power" for an additional 100 bonus points, obtain a 12-volt motorcycle battery and a solar charger. (Perhaps you could borrow a solar charger from a college physics department.) Use the battery until it is fairly well discharged, then connect it to the solar charger and charge it on sunny days. At the slow charging rate of the solar charger (120 milliamps in full sun for the one our group used), it will take many hours to charge up the motorcycle battery. This charging might well start in the middle of May.

Power Supply

Two fully charged automobile batteries will run a transceiver with 5-Watt rf output for the full Field Day period. This includes running a 12-volt lamp during the night. (If the weather is cool, you can use a gasoline lamp, such as a Coleman lamp, for lighting, and its heat will be appreciated.)

Transceivers

The transceiver for the station should be one which has a single signal superheterodyne receiver. For best results, the receiver should have an i-f filter of 500 or fewer Hertz, plus an audio filter. A Ten-Tec Argosy transceiver used in its low power mode is an excellent Field Day transceiver. Although you can make contacts with transceivers with direct-conversion receivers, the fact that this type of receiver brings in each station at two places on the dial makes undesirable QRM. There's more than enough QRM during Field Day without adding to it by using a direct-conversion type of receiver! It should go without saying that it's desirable, if not necessary, to have a backup transceiver available.

Antennas

Having excellent antennas is of greatest importance for QRP Field Day stations. It's helpful for a station to have two antennas and the ability to instantly switch between them. If possible, the antennas should have gain as compared to a conventional half-wave dipole.

An allband tuned doublet or "center fed zepp" with 66 feet each side of the center is a good antenna for Field Day use. In 1983, using only this antenna, the Principia College Amateur Radio Club made 394 contacts in 24 hours with the 5-Watt rf output of a Ten-Tec Argosy transceiver. With its wires running north and south, the antenna was an unusually good half-wave dipole on 80 meters. On 40 meters, the antenna was "two half waves in phase" for a gain of 1.8 dB in the east and west directions (as compared to a dipole). On the 20- and 15-meter bands, the gain in the major lobes of the four-leafed-clover pattern was probably more than 2 dB. Because the antenna was in the form of an inverted vee with its center up 40 feet and the ends up 15–20 feet, the antenna sent well in all directions, on all bands.

If your station has two antennas, the second antenna should have much gain on the 20- and 15-meter bands. If the station is on the East Coast, a beam antenna aimed west would be the logical kind of antenna to use. For a West Coast station, a beam antenna aimed east would be appropriate. In the middle of the United States, you need a bi-directional beam. It isn't practical to rotate a beam on Field Day. This takes too much time, even if you could devise a 12-volt rotor or "armstrong" rotating system. Bi-directional beams are not hard to build and do work well. Vertically polarized bi-directional beams send out a wider beam than do horizontal beams, and this makes them good for Field Day use. An end fed, 20-meter, vertical W8JK, "end fire," bi-directional beam fed with tuned feeders works well on both 20 and 15 meters and has a gain of 4 dB as compared to a dipole (for both bands).

Each Field Day antenna system should have its own antenna tuner, and there must be a coax switch with which the operator can instantly switch the output of the transceiver from one antenna tuner to the other. All Field Day antennas should be fed with balanced tuned feeders so that the 5-Watt rf output of the transceiver will get into the antenna as effectively as possible. Ordinary vertical antennas (not vertically polarized beams) are not usually effective for use with the QRP Field Day station.

Field Day Operating QRP

Having a meeting of the operators, loggers, and dupers to discuss the rules, operating, logging, and duping procedures is helpful. To make the best score, it's a good idea to have the best operators do most of the operating. Other operators are usually glad to contribute by doing the logging and duping. It's also good to use call letters that are short, easy to send, and easy to read, preferably ending in a dah.

The following ideas will help a QRP station make contacts:

1. *Answer* CQs rather than call CQ.

2. Use a code speed that isn't too fast. The sending should be clear and accurate.

3. Conserve time by making the exchanges as brief as possible. Use a minimum of words. Sending de (your station's call) without sending the other station's call saves time.

4. Quick "tailgating" after a station has completed its exchange often results in a quickly made contact.

5. A computerized keyer programmed to send the exchange when a button is pushed is helpful.

6. Do not spend too much time trying to make a contact with a given station. If a contact is not made after three calls, move on and call another station.

7. Go to a less crowded part of a band if you cannot make contacts in a crowded part of the band.

Band Selection and Band Changing

Listening to the bands immediately before the contest starts will give an indication of which bands are open and active. (There will be many Field Day stations testing.) If the 15-meter band is open, you can make contacts there until the band dies or is "fished out." Twenty meters is also a good daytime band on which to start and is usually good well into the night. It's a good idea to spend most of the time on bands for which the antennas have the most gain. Forty meters is usually good both day and night. Eighty meters is strictly a nighttime band and, with a good antenna, will provide many contacts.

The station should stay on a band as long as it is making frequent contacts. When the number of contacts per hour starts to decline, it's time to change to another band. Later in the contest, the station can go back to bands that were fished out earlier and may find many "new" stations to work. Using separate log sheets for each band helps in making out the summary sheet after the contest is over.

Having a good support group of people who are not operators is helpful. Wives and other family members of the operators can supply food and soft drinks. A Saturday evening pot luck supper in which the operators can take turns eating and operating adds to the enjoyment of Field Day. Operators can bring their own Saturday noon lunch, Sunday morning breakfast, and Sunday noon lunch.

Setting Up the Station

Some clubs like to set up their antennas on Friday evening. The rest of the station is set up on Saturday morning. This often takes more time than one would think. If the group starts at 9 a.m. Saturday, everything can be ready and tested by the starting time. You can use a good alarm clock (hand wound or battery operated) for logging. It's easier and less confusing to keep the log in local time, rather than to try to keep it in UTC.

A check list of everything needed will help to keep the group from forgetting anything. The Boy Scout motto "Be prepared" is a good one for Field Day. Being extra well prepared helps prevent Murphy's Law from shutting down the station.

Keeping the Socializers Happy

The socializers in a club are likely to be "phone hams" ("phoney hams" in the eyes of the serious contesters), who have little interest in helping to run a QRP battery-operated CW station. To meet their needs, they can set up and operate another station with call letters different from those the station of the serious contesters uses. This station could be called the "fun station," and the station of the serious contesters the "contest station." The fun station should be located quite far, but not too far, from the contest station and powered by commercial power mains. Using commercial power eliminates the obnoxious noise of a generator and the unpleasant work of keeping the generator running.

In most cases, the QRP contest station would operate on CW and the fun station on the phone bands. The contest station would have the best possible antennas, while the fun station would use a coax-fed antenna with parallel elements or other devices that would make the antenna work on several frequency bands. (A "trap vertical" with radials lying on the ground could be used; it would be easy to put up and would not take up much space.)

The fun station should be managed in ways that would encourage visitors to become interested in amateur radio. The fun station operators should explain amateur radio to visitors and give them materials designed to get people interested in the amateur radio hobby. (Nearly all hams like to talk about their hobby to any people who will listen to them. Hi!)

Another good fun station activity would be to let visitors get behind the microphone and make contacts. The licensed operator in charge of the station should carefully supervise these contacts and be responsible for them. Visitors could also share in the logging of contacts and marking of the dupe sheets. These activities, shared with visitors, would provide training in contest operating techniques.

The fun station should operate only on frequencies that will not interfere with the QRP contest station. Given a reasonable distance between the two stations and the fact that one station is on CW and the other station is on phone, interference between stations should not be a problem.

To arouse interest and stimulate activity, the operators of the fun station might be encouraged to be competitive enough to try to make as many contacts as the QRP station makes on CW. (It is assumed that the fun station will be a medium powered station.) If the fun station operators do not want to stay around all night, they could try to make as many contacts per hour as the contest station during the times when the fun station is on the air.

If possible, the fun station should use call letters that will naturally promote fun. One year the use of the call letters K9BO brought many humorous remarks from operators of stations worked. One of these was "Canine B.O., you must be a dirty dog." That year, it was singularly appropriate that K9BO made its last contact with station WØPU, operated by a female operator who gave the call letters as "Whiskey Zero Pink Underwear."

On the next Field Day, make both your serious contesters and your socializers happy by running two stations, each with its own call letters. May your fun station provide lots of fun and may your QRP Class 1A battery-operated contest station make the best score that your club ever had!■

NEVER SAY DIE

from page 12

the air, you'll always be making a first impression on someone.

I have a fairly good vocabulary—the result of living with an upper middle class family which made a point of "looking it up" when anyone misused a word. Just as I dress to convey to others the real Wayne Green—I also am careful in my speech when meeting someone new. As I know them better I am more flexible in my dressing and my speech. I use dirty words sparingly, using them to communicate where needed for shock value—extreme emphasis.

The language used between a group on a 75m net who have been talking with each other nightly for months is going to be different from that used in first contacts. We should allow more latitude.

What Can We Do?

Okay, let's address the situation head on. Let's say you hear some jerk going way beyond the bounds of decency in language. What should you do? Should you break in and arrogantly tell the sonofabitch off? Should you merely tune off the channel and sigh over what ham radio has come to? Should you try to jam the bastard? Note my use of emotion-stirring words as I talk about the people who are making you mad—mad when you just think about it! I suspect you agreed with my expressing my obvious distaste for these filthy, disgusting people with appropriate words.

My recommendation is to break in when you hear the bounds of propriety being overstepped—and I mean way overstepped, not just stretched a bit. Break in and tell the chap you find his language inappropriate for amateur radio. Be polite but firm. I guarantee he'll try to get you so mad you'll be inclined to sink to his level—so my suggestion is to make your statement and then tune the hell off the frequency before he can answer. Think about it. One thing your nervous system does not need is an attack on you—even over the air. It doesn't take very many such acrimonious events before you'll find yourself avoiding your ham rig. No, say your piece as unemotionally as you can and leave the channel so you won't get burned by the fireworks.

You may think that your efforts to clean up the bands will be wasted. But look at it this way—tens of thousands of hams are reading this editorial. Maybe only a few hundred will have the guts to actually do something about the language on our bands, but by the time a bad language user has been reprimanded—and been unable to pick a fight over it, thus getting his jollies, he'll either start to clean up his act or will find himself hesitating to turn on his rig. If hamming isn't fun, we don't do it—so the idea is to make it less fun for the people who are making it less fun for us.

No, it is not necessary for you to give your call letters when you are helping to clean up our bands. And none of that sanctimonious crap (heh!) about it being illegal to transmit without giving your call. I don't see the rules helping us with bad language or bad operating, so don't wave rules at me. I use my call letters when I think they are needed, not to satisfy the FCC. The FCC could care less. They're getting out of the monitoring business anyway, so if we want our ham bands to be fun we damned well have to accept the responsibility for keeping them fun.

The H&R Block

Non Illigitimi Carborundum—don't let the bastards wear you down. Wear them down instead. Wear them down by hit-and-run tactics—what I call the H&R Block.

This technique is effective on the low bands—and to some degree on VHF. But when you run into foul language on your repeater you may need a more effective approach. Here, where your miscreant is nearby, you have a whole array of possibilities.

Just as I recommend every radio club have an I-Team—a group of three or so experienced amateurs who can keep their cool who go out and investigate every interference complaint against a local amateur—I also recommend clubs appoint a UFO-Team to handle perverse operators. UFO—Unofficial Friendly Operators.

The first step for the UFO-Team is to pay a friendly visit to a perpetrator and explain the club's view of his operating. If this doesn't work, a second visit with some tapes of his activities, perhaps accompanied by a somewhat larger representation from the club, might get the message across. Hard-core nasties may call for creative measures. Would tapes of his operating and a note to neighbors, his family, his employer, and so forth help create a more relaxed atmosphere?

When the crazies group for support, your approach might best be to work on each one as a separate case and ignore the group. Each then can individually feel the weight of your group disapproval, but without the support of his crazy group to back him up.

Don't Be Officious

If you use your strength to swat a flea with a sledge, you'll lose your credibility. Hassling someone for minor indiscretions will waste your power. Save your muscle for the hard-core cases. You have to be careful in selecting a club UFO-Team. There is a tendency for the power-seekers to find these jobs. You'll soon find them with UFO-Team signs on their cars, flashing red lights, and a barrage of tape recorders in their shack as they tune the ham bands, eagerly seeking anything and everything to hassle.

Feedback

If your club has some success with an I-Team or a UFO-Team, make sure someone writes it up so I can publish it in *73*. We don't have to live with bad operators—we just have to retrain them. Let me hear your war stories—particularly those where you've won some battles.

ATLANTA IN JULY?

The biggest hamfest in the Southeast is the Atlanta HamFestival . . . this year July 19–20. There are only a few major hamfests where you'll see all of the major manufacturers showing off their newest gear—where you can corner them and get answers, where you can get your hands on just about every ham product made—and Atlanta is one.

Yep, I'm planning on being there and I'll be giving a performance—bring your seat belt and your tranquilizers.

Atlanta is always a joy to visit. It's really geared for visitors. They're working to rebuild Underground Atlanta, but in the meanwhile you don't want to miss the refurbished Cyclorama—their updated zoo—and Stone Mountain, a nearby amusement park.

For you fat people (like me) there are great wonders. I seldom miss a pass at Aunt Fanny's Cabin. When I'm able to get someone to invite me out, I enjoy The Abbey—one of Atlanta's best (and most expensive) restaurants. Fatties will also go bananas over the buffet in the Marriott. There aren't many dessert buffets, but they've got one. Ice cream sundaes and banana splits, ice cream on pies, ice cream and cake . . . mmmmmmm. I hope they haven't changed that.

Jazz fans will enjoy Walter Mitty's, where you'll probably see the Trio-Kenwood gang tripping.

It's time you got serious about packet radio anyway, so check 'em all out at Atlanta.

Y'all come, y'hear?

CAN WE REBUILD OUR LOST INFRASTRUCTURE

A brief industry meeting was held during Miami Hamboree last February. This was a follow-up on last year's meeting where it was decided to go ahead with a ham comic book project. The industry agreed to ante up $10,000 for the project, which would be matched by an equal amount from the ARRL. The industry ante on this is still light.

Not much has happened yet on the project. It was discussed and agreed that it should continue as a test to see if this approach will result in some growth. There was no disagreement that amateur radio is in desperate need of growth—that without *something* to make it grow, we're looking at a dying hobby.

There's a tendency to put todays kids down—to blame the kids because they're not getting excited about amateur radio. I hear lots of excuses—well, hell, the kids are playing with computers these days—they're watching television. Bull. When I was a kid there were plenty of other things for kids to be interested in—has everyone forgotten that kids have always had plenty of things to do?

No, blaming the kids is a copout. The problem isn't the kids at all, it's plain and simple our own fault. I got interested in amateur radio about the time I entered high school—lo and behold, there was a school ham club, W2ANU. We got together a couple afternoons a week and talked hamming. We put our club station on the air and made contacts. We pored over

QST and *Radio* together. We visited each others' ham shacks.

We hams sat around arguing with each other twenty years ago when this whole infrastructure was destroyed by the League's "incentive licensing" proposal. Thousands of school radio clubs folded, right along with 85% of the ham stores around the country and 95% of the American manufacturers. That was a catastrophe we're still paying for.

Without the thousands of high school ham clubs to fan the starting flames of ham interest, this whole source of newcomers has almost totally dried up.

We didn't help this situation with our regular community ham clubs. In almost every instance these clubs became controlled by old-timers—old-timers who wanted to talk with old-timers, not kids. Kids are noisy. Kids ask a lot of dumb questions. Kids mean the club has to have a damned code class. Kids mean someone has to try and teach theory. Kids are impatient with the usual endless club bickering. Kids are impatient with long boring business meetings. Kids get fed up with committee reports and interminable arguments over trivia. So old-timers have run the kids out of most clubs. So we don't have any kids these days—surprise, surprise.

I'm wondering—even if a ham comic book does arouse some interest—so what? Where have the kids to turn for reinforcement? If my high school hadn't had a ham club, would I have had my interest in hamming fanned enough to get a ticket? Maybe. Probably not. I could easily have gotten involved with audio and hi-fi and drifted away from amateur radio. I had many friends who did just that.

It wasn't hamming itself which attracted me as much as it was having fun with other kids. I first listened—SWLing. Then I started building electronic gadgets and radios. Then I was guided by the school radio club members toward getting my own license. This was reinforced by daily contact with other similarly interested kids. From there I got on my roller skates and started visiting the nearby hams I heard on the air. I think I visited every active ham in Brooklyn.

The code put me off for a long time. Some of my friends got W2Ms. I'm sure I would have been licensed at least two years earlier if I'd stayed in the high school with the radio club (Eramus HS), but I changed to a small private school with no ham club and lost the impetus. When I went off to college they had a ham club (W2SZ) and I almost immediately got licensed. This is what I see happening today—even when kids get excited about amateur radio, the excitement almost always blows over without the constant reinforcement of a school ham club.

So I'm not at all convinced that a ham comic book is going to do much for us in the long run. No, we not only need to make the fun of amateur radio known to kids, we have to rebuild the whole infrastructure which used to bring kids into the hobby. We need to get ham clubs back into the schools. We need to get every active community ham club dedicated to getting kids involved and seeing that their first tentative interest is fanned to a roaring flame—maybe even to a license. Avuncular old-timers like me aren't what kids need, they need peers—other kids to help them—to talk—to enthuse—to share excitement.

How in hell are we going to do all that? Well, it's not as hard as you may think. Yes, of course it can be done—done despite all the lame excuses about kids being attracted to computers these days. Sure they are—they have computer clubs in school—and they visit each others' homes and play with their computers. They talk about computers—read about 'em—they play games, they program and swap programs. They break the protection on programs and swap them. They get on the phone and break into bulletin boards—into banks—into military base computers. Talk about fun!

Amateur radio has every bit as much excitement as computers—and I've done the computers bit too. Computers are fun, no question, but they're no competition to working a rare DX contact—making a DX aurora contact on two meters—getting a new country via OSCAR—working a new state on 10 GHz from a mountain—operating in a DX contest—getting a good picture on an SSTV screen from a new country—visiting 9B1MM in Katmandu or 9M6MO in Kota Kinabalu in person—working South Africa with a 2m handie-talkie through a crossband repeater—getting a call on 20m from King Hussein—working Arthur Godfrey on safari in Africa and saying hello to an old friend of my father's who was with him.

I remember a 1946 night—after a college radio club meeting when a bunch of us got into my old '41 Ford and drove to the top of Mt. Greylock in nearby Western Massachusetts. We had my SCR-522 and a 16-element beam on top of the car and had a ball. It was bitterly cold, so we set up the beam and turned it with a couple pieces of string running out the car window. Huddled around the 522 in the back seat, we worked dozens of stations—all the way to Boston!

Newspaper articles about our ham activities will help strike a spark of interest in kids, but without school ham clubs to follow up, it's a waste of time. Sure, we need PR in magazines, newspapers, on TV, radio . . . every medium. We need to demonstrate in shopping centers and malls. We need to provide communications for parades, rallies, and other community events. But most of this will be wasted if there isn't the follow up—the school clubs.

Okay, we need to rebuild the high school ham clubs. That'll get the kids in the 14–17 age bracket. Back before the ham dark ages—back in the 50s—ARRL studies showed that 50% of the new hams were either 14 or 15 years old. That's when it happens. I think we can start as early as ten these days, and I'm working on a fiendish plan for that. In the meanwhile let's go with what worked so well for 17 years after World War II—hooking the high school kids. Let's talk about getting high school ham clubs going again—rebuilding the infrastructure which we know worked so well.

It won't be as hard as you think. Better, it will be more exciting—and also more frustrating—than anything else you've done in amateur radio. Your first obstacle will be the resistance of the members of your own radio club. People in general and hams in particular tend to do everything they can *not* to change—often in the face of overwhelming evidence that change is not just necessary, but critically important. People in general and hams in particular are terribly lazy. They will go to incredible extremes not to do something. This is human nature and, contrary to most evidence, hams *are* human. Well, some are.

Let's not get into what hams are. Most of 'em are obviously crazy. Most are cheap bastards. I admit to both of those ham normalities, so I'm not throwing stones, just calling a spade a spade. I think, by almost any measure, any ham in the ham industry has to admit s/he is crazy. There's no other rational explanation for such irrational profitless behavior.

My recommendation as to the easiest way to get ham clubs started in schools is to encourage our community ham clubs to get going on this as a club project. A small delegation from the club needs to talk with the school principal and explain the importance, to our country and to the kids, of getting them interested in a high-tech hobby such as amateur radio.

The next step is to start regular meetings—maybe once a week—preferably during school hours, if at all possible. Get the principal to allow a club meeting in lieu of a study hall. After-school clubs are often up against serious problems such as busing and sports conflicts. If you can't get a school period, then settle for after school.

The principal will quickly remember that a club has to have some sort of faculty advisor—and that means, particularly after school, overtime pay, which isn't in his budget. If your club can guarantee that it will supply an advisor, you may be able to handle this hurdle. The incipient hams will need someone to tell them about the glories of hamming—and perhaps organize theory and code courses. It's an opportunity to get the kids to come to the community club too—and even to visit local ham stations and maybe get fired up by talking with some DX.

If the principal isn't too interested, you may be able to work through a child or grandchild of a club member attending the school.

If you run into a particularly tough case you might point out that the lack of young radio amateurs has resulted in America falling far behind in engineers—with no growth in engineering graduates in over twenty years despite over a ten times growth in electronic sales. This is why Japan has been able, one by one, to take our consumer electronic industries away from us. Only by getting kids interested in high-tech careers will our country be able to reverse this destructive trend—and that means starting high school kids toward careers in electronics, communications, and computers. Every school in Japan has an active ham club.

Let me be blunt—I don't know for sure that we can pull this off, but if I wasn't pretty damned sure, I wouldn't waste my time trying. I don't have a record of failure—and I don't intend to break that record now. If you really believe I

can't do this—if you're not going to support me—please let me know why. If you can think of anyone else in the entire world who you think can do this better than me, let me know—maybe we can get him to do it.

R.I.P. POOR LRPC

One of the reasons I've been so concerned over the shortage of new hams has been my work with the FCC's Long Range Planning Committee. I was appointed to the committee when it was formed five years ago and, despite its meeting in Washington, I don't recall having missed more than one meeting in all that time.

The purpose of the committee was to tackle America's need for an emergency communications system which could be expected to survive even the most serious of emergencies...a nuclear attack. It became obvious early on that our commercial and military communications systems were totally inadequate for this need. The committee recognized that only amateur radio had the potential.

However, amateur radio had only the potential for this, not the actuality. The volume of communications which would be needed should there be a nuclear attack is so far beyond the present capability of amateurs to handle that we are almost worthless right now. The millions of messages involved can't possibly be handled with our cumbersome, slow Morse-code traffic nets or even phone traffic nets. You know, it's estimated that 80% of us would be unable to pass a code retest if one were given.

Remember that any serious emergency wipes out telephones. Remember that most commercial communications services are on different frequencies and are therefore unable to intercommunicate. We've seen many times where only amateur repeater groups have been able to provide the interconnect between police, fire, ambulance, and other services.

The committee saw that any practical solution to the need would entail two major changes. First, we would have to get amateur radio into vigorous growth before we could expect to have enough hams to provide the needed service. Second, we'd have to get hams to develop technologies such as RTTY and packet radio far beyond where they are today to achieve the message throughput needed. The committee also recognized that for an emergency communications system to be dependable it must be in everyday use.

The FCC commissioners appreciated the serious need for amateur growth, but the only move which seemed to have any real prospect for bringing about this growth was the no-code license. This had worked exceptionally well in Japan, bringing enthusiastic teenagers into amateur radio by the hundreds of thousands.

When the ARRL fought the FCC's proposed no-code license and defeated it, the FCC, with no other known options for producing new amateurs, gave up in disgust. They dumped the LRPC on FEMA, the Federal Emergency Management Authority, which, as I predicted, completely ignored it. FEMA never held one single LRPC meeting in two years. The FCC recently dusted off what was left of the LRPC and held what appeared to me a brief wake, pronouncing the committee a rousing success, complete with a nice plaque and an autographed photo of Ronny for retiring Defense Commissioner Mimi Dawson. Mimi certainly gave it a fine try and did the best she could under the circumstances—a bravo to her.

Perhaps I should share the apparently common feeling that the situation is totally, completely hopeless, so why bother to waste time trying to fight it? Well, I don't think it is hopeless as far as getting amateur radio growing again. I even think, with *73* helping, we may be able to develop the high-speed automated digital message system we need. Heck, we already have the technology; all we need are the pioneers to work out the details and battle old-timer inertia to get it accepted. If we can get growth through kids, we'll have our pioneers.

But you tell me. Should I give up trying to fight amateur apathy, the ARRL, the FCC, and City Hall? Maybe you'd rather read about my misadventures on 20 meters. After all, the chances of a nuclear attack are almost zero anyway, what with the promised nuclear winter effect which would wipe out most of civilization. Amateur radio, as bumbling as it is, can usually cope fairly well with small localized emergencies such as earthquakes, floods, and vol-

canos—so why bother trying to develop more hams and a better communications system?

And, as far as getting amateur radio growing so America can generate engineers, technicians, and scientists so we can compete with Japan, perhaps it's time America got used to being a second-rate country—the way England has. Maybe we shouldn't bother to try and regain our former pride in our technology. It's so much easier to just let our kids enjoy drugs and television—to ignore their smoking cigarettes and spending their nights cruising. Recent statistics show the average American youngster spends an average of two and a half minutes alone with his father a day without the TV set on. Do we even care about our kids—about our country—or amateur radio? I see no evidence of anyone caring.

What do you think? I don't want to turn into a pest.

OUR HAM POPULATION

With a little over 400,000 licensed amateurs, we have a fairly strong hobby, eh? Of course we're seeing an increasing loss of newcomers, but the new ten-year licenses make it so the total number of licensed hams has stayed about the same.

What about concerns over the average ham age now reaching 56? How did that happen? I talked with an old-timer the other day who had an interesting perspective. He runs a ham store and he's observed that a surprisingly high percentage of the aging licensees are the wives and close friends of hams who were given or virtually given their licenses twenty-five years ago when that was popular. These Techs, now in their 40s and 50s, have never had enough interest to bother learning much about amateur radio, or to be particularly active. A more realistic guess at the even remotely active ham population might put it below 200,000.

The bright side: Most licensees who drop out each year are from the inactive half of the ledger. We're also losing an increasing number via Silent Keys, as the average age increases. Remember, the average life of men in the U.S. is around 72 years—which means, as I've pointed out before, by the time you're 72 half your friends will be dead and the other half dying.

We do have enough time left, however, to get busy and Elmer local school radio clubs so we can get amateur radio going again. Yes, I've heard all about computers taking the kids away from amateur radio. Baloney. Kids have always had plenty of interesting things to do. If hamming is fun we can interest kids in it. But we do need the school radio clubs to fan that spark of interest and get 'em licensed.

These days, with packet radio growing so fast, we have even more to talk about to kids. Packet is a way for them to use their computers and do something really fun with them.

I hear whines about kids not having the money it takes for amateur radio equipment. Heck, if kids can support a $100 a week cocaine habit, they should be able to put together a whopping ham station just by avoiding drugs. Any kid that really wants to can find after-school work and make money.

Speaking of money, what about the poor old-timers who are living in poverty on Social Security? I don't know about where you are but around here it's tough to find people for the available jobs. There's plenty of part-time work—and an unlimited number of ways for people to get into business for themselves.

So let's not be complacent, smugly assuring ourselves that we're 400,000 strong. Let's get to work rebuilding our hobby—getting youngsters. My goal for us is 1% of our population—yep, 2.5 million hams—over ten times as many as we really have today. If you get started with school radio clubs, I'll publish the simple construction projects and news of exciting new ham activities such as packet radio. Who knows, we may even get America back into high technogy!

GOD WILL PROVIDE

A few years back...oh my, it was 1966, twenty years ago...I visited Robbie 5Z4ERR...he used to be VQ4ERR when Kenya was part of the British Empire... which was then known as Great Britain. I suspect the term today is generally used in irony. Anyway, Robbie, who had been writing for *73*, suggested it would be nice of me to visit Kenya—and maybe go on a hunting safari.

I'd just read a book on how to go on an African Safari for $690. I checked, and sure enough, I had $690 burning a hole in my pocket. Should I start a new magazine or go on safari? Easy choice. I wrote an editorial in *73* asking if there were any hams interested in going with me on safari. It turned out there were two, so we did it.

No, I'm not going to write a day-by-day account of the trip...at least not now. What I'm gradually getting around to has to do with Kenya at that time, just a few years after gaining independence. Robbie, a British chap, ran the largest drug store in Nairobi—and had the biggest signal out of Africa. Oh, we had a lot to talk about!

After the $690 safari, which was most successful, thank you... while my trophies were being cured and shipped back... Robbie and I drove to the Serengeti game park for a few days. Robbie explained that one of the big gripes in Africa at the time was the attitude of the missionaries. The Europeans could see that what little they'd established in the way of civilization was unraveling, so they warned the missionaries to get out while the getting was good.

No, God Will Protect Us, they pioused. So then, when the blacks, caught up in *Uhuru*—freedom—started raping and killing, the cries of anguish arose—oh woe, please save us. Robbie was griping that then people had to endanger their lives to rescue these turkeys.

I tried to explain to Robbie that the inability to cope with an impending disaster is a human trait, not one isolated and perfected by missionaries. Oh, they saw the danger, but they just didn't believe it could happen to them. They really believed that God would somehow spare them, so they were very upset to discover that God helps those who help themselves—perhaps a new concept to them.

This came to mind as I thought about the similar reaction of businessmen. When the cash gets short they look around for temporary expediencies, some of which can have devastating consequences. How many times have I called *73* advertisers to see what they're planning to run, only to be told they're short of money right now, so they're going to cut their advertising. None ever survive.

Yep, I know this seems self-serving—after all I'm selling advertising space, right? Yes, I am...but more important to you, the reader, and to the industry, what I'm selling is one of the most critical aspects of any business—communications with customers and potential customers. No customers, no business...so when the connection to sales is cut, the business dies.

Most of the ads in *73* are run by small ham-owned companies. They're spending a bundle on ads in *73* in order to reach you, hoping desperately you'll buy their products. Few of them (any?) know much about advertising, so you'll see some terrible ads in amongst the few good ones. Rather than just skipping over the bum ads, you might take pity on a fellow ham and drop him a note explaining your reaction. Maybe he'll do better as a result.

Unless you're very unusual, the day is going to come when you and a ham friend or two get to talking about getting into the ham business. You'll have some gadget or some service and you'll want to give it a try. What could be more fun than being in business selling a ham product or service? Well, if you ask those who are in the business, you'll find there are many things far more rewarding—like jumping naked into a pit of hot tar.

Entrepreneurialism is a mental deviation which is generally more concentrated with only- or first-children, but can hit almost anyone. Hams seem particularly susceptible to this aberration, so watch out. One of these days you'll build some gadget which your ham friends will want. Will you make one for them? The next thing you know you're running small ads in *73*. Then bigger ads. Then full pages. Then the sun spots fade away and so do sales. Instead of advertising smarter you start cutting ads...dum de dumm dumm.

When sales are good you don't worry about making your ads work better—about getting the most out of 'em. When the hard times come it's too late to do the learning you should have when you had the money. Pity.

I can hear my telephone ringing now—I'd like to get into the ham business—how can I find a product to sell? My first warning is not to try to sell to hams—a tight-fisted bunch of retired old men bent on making sure newcomers suffer just as much as they did to get their ham ticket. Well, most of 'em are that way, but we do have a few hams interested in new things—or else we wouldn't have several thousand packet-radio enthusiasts. Perhaps there's some hope yet.

My own formula for finding products to sell is to make an annual pilgrimage to where most of

THE FORMULA FOR TWO METER DX:
MTT144/28R + MML144/200S = VUCC!

MICROWAVE MODULES LTD.

The MMT144/28R GaAsFET transverter and companion MML144/200S power amplifier give you ultimate flexibility on 144 Mhz. The MMT144/28R features ALC, 25 watts RF output, and built-in +600, −600 Khz offsets for FM repeater operation.

The MML144/200S offers three switched input drive sensitivity levels—3, 10 or 25 watts for a full 200 watts output! A low noise optimized GaAsFET preamp is included.

the new products are being invented and developed: Asia. I try not to miss the Japanese Consumer Electronic Show every October (there are generally a dozen or so hams on the fall show tour), plus CESs in Korea, Taiwan and Hong Kong. They're one after the other. I'm importing some great electronic gadgets from Asia that I've discovered on these trips. For instance, we're selling about 500 Apple disk drives a month and a couple thousand swivel bases for monitors with power switching and protection built in.

The entrepreneur will find inspiration almost anywhere. I'll bet I come up with a gangbusters idea at least once a month, with idea-ettes almost daily. Now that I've got my publishing and retailing businesses running fairly well, I'll be looking for coconspirators and investors to start more businesses.

You can bet that when cash flows glaciate, I'll be pumping out the PR and advertising, not cutting back on ads to save money. Every business runs into cash problems—it's part of the real world.

One piece of advice I give every firm consulting me: When things are going well it is time to invest in a good PR person and a writer. I know of many multi-million dollar firms which would be going strong today if they'd had such a team on hand when the going got rough. Many firms with excellent products and services went out of business for this lack.

Am I being a nudge about you're getting into business? I guess I let my enthusiasm get away from me and write too much about it. I just get so darned fed up at hamfests hearing people plead poverty—poverty in the midst of plenty—plenty right there for those with the guts to go for it.

I wonder if there is any correlation between hams who try new things—who get involved with packet radio, who get enthused over OSCAR contacts, who get on 2m SSB—and being adventurous in life...in business? Seems to me there might be. Some hams get their Tech ticket and spend their declining years talking over a repeater—never really saying much. Some are into DXing, then into high-speed CW, then having a ball with slow scan. They never get bogged down for long.

One of the great charms of RTTY has always been the opportunity to talk with the more interesting and adventurous hams. The packet crowd is now saying the same thing. Plus, we seem to be able to communicate better in writing than we do on voice. These activities which take some extra effort are a fine filter to block out the boring turkeys. No, it isn't perfect, but it's good enough to keep most of us going on RTTY and packet well beyond our pioneering days.

Now, getting back to the God Will Protect Us syndrome—I see that same attitude—the same blindness to approaching catastrophe—on the part of our lower-intelligence old-timers. Here we have a hobby which depends totally on the use of incredibly valuable radio spectrum, a limited resource worth billions of dollars to commercial interests. We're an aging and shrinking group. We know that virtually all the technical advancements we used to contribute came from younger hams, yet we've allowed this resource to be almost wiped out. It's been a generation since we've done anything of value to warrant our use of our bands. Indeed, by keeping out the young experimenters we're now using only a few of our allocated bands at all. Will prayer save our hobby? Let's either get those prayer wheels going or get cracking on helping ourselves by getting school radio clubs going. Perhaps if we set all of our computers offering prayers 24-hours a day to save amateur radio from our own neglect, we might be able to relax and rag-chew without that guilt feeling. How about it you software chaps, have you a program which will take care of this for us?

DO YOU WRITE?

I'm looking for some columnists to keep us up to date on what's going on in the dozen or so related hobbies we call amateur radio. We're covering some okay, but not enough. For instance, perhaps you're a true 160m fanatic—fine, you'll have a lot more activity on 160 if you let everyone know what's happening there and how much fun it is. We're interested in antennas, 160m equipment, contests, special events, band conditions, what DX is available on what frequencies, when, and so on.

If you're an 80m guru, we're interested in the same info—monthly. We're also interested in special activities such as RTTY, high-speed CW nets, and service nets. There's a lot going on on 80. Is there anyone who can tackle it?

Ditto the above for monthly reports on 40m, 20m, 15m, and 10m. In addition, if there's enough interest, we might have a separate 10m FM report. I don't know if there's enough activity on 6m to fill even a one-inch column, but if there is someone who lives and breathes six meters and can fill us in on what's happening there, let's hear from you.

There is so much doing on two meters I don't know how we could cover that. If there's someone with the guts to try, I'd like to hear what you propose. Trying to cover voice repeaters, RTTY repeaters, digipeaters, moonbounce, meteor scatter, SSB, CW, aurora...I don't think it can be done.

220 is easier—any volunteers to see what can be done about making 220 more popular? We need repeater lists, simplex channel data, contest information, equipment news, and so on. Perhaps we need a 220 contest?

430 is a busy band in many areas of the country, with some TV on the low end and a passel of repeaters higher up. Is much being done during contests? Simplex? Mountaintopping? Moonbounce? Spread spectrum? Is there a volunteer?

1250 MHz—volunteer? There's more and more ATV here, EME...and what about microwaves—like 10.5 GHz, 24 GHz, and so on? Is there a volunteer with enough interest to try

and get more activity on these bands? We need to know what's being done, what new equipment is available, how the bands do during VHF contests, and so on.

We need a column for SSTV. And how about high-speed CW—anyone into that who can tell us what's going on—where to listen—what equipment to use? EME. . . volunteer? We have OSCAR orbits, but how about news?

We have an estimated 150,000 American hams who are actually active in some way. Most of us are creatures of habit. We get stuck rag-chewing on 75 meters and tend to forget the fun of climbing a fire tower on top of a mountain in the middle of a well-below-freezing night to try for a 10.5-GHz contact with a new state. Some fun. So if you are having a ball with some aspect of amateur radio and would like to get more of us interested in your insanity, the best way to promote it is with a monthly column in *73*, telling us what's going on, how to do it, and how much fun it is.

Even though I'm as habit-frozen as just about anyone, columns and articles on ham activities I haven't yet tried eventually get to me. Over the years I've been forced by magazine articles and columns to become an RTTY fanatic, worked more than my share of DX, have a big certificate collection, have done my bit with 75m DXing, was a pioneer on six meters, have the record for states worked on 10.5 GHz, had my own repeaters on several bands, operated SSTV from several countries, and so on. If you're enjoying ham radio, get more hams involved with your particular interest with a column.

If you'd like to give it a try, put together a sample column and send it to me so I can get an idea of what you can do. I'll pay modestly, but your main reward will be increased interest in your activity. I prefer to get both a disk and a printout so we won't have to retype your material. We're completely automated these days, so we plug your disk in, edit your stuff, then feed it right into the typesetting system.

I'll be judging your columns on how much you obviously know about your subject, how persuasive you are, and how much you'll be able to contribute without depending too much on material from readers. As a hard-core stick-in-the-mud ham, one who tends to stay with what I'm doing unless dynamited into something else, I'll be looking to see if your column gets me to thinking about giving your interest a try. It won't hurt for you to include an outline of things you'd like to cover in future columns.

I got stuck for about a year talking to the same bunch of hams on 75m one time. It wasn't until the excitement of six meters opening to Europe during a sunspot high that I broke away. The enthusiastic articles and reports finally did it, getting me to convert an old FM radio to see what the fuss was about. WOW!

In order to keep columnists on their word processor keys, I want all of you to send me a Feedback card (page 80) every month telling me how you rate 'em. If they lose out in the ratings, I'll look for someone you'll like better. It's all too easy for columnists to run out of material and get dull. There isn't any excuse for dull in a bunch of hobbies like ours.

I don't know whether we'll get you going on high-speed CW, on EME, or what, but I'm going to do everything I can to get you off dead center. If you aren't an expert, at least contribute your news to the experts. . . and help me get as many hams subscribed to *73* as we can. Talk it up, okay? It's better than reciting your ham gear serial numbers.

ASIAN TOUR

The Consumer Electronic Shows in Japan, Korea, Taiwan, and Hong Kong are back to back in October, making it possible to get to all four in a two-week Asian trip. It's a fast tour, with one-day travel and then two days in most countries, but it gives you a chance to both see these interesting countries and get to their electronic shows.

Compact disc fanatics will love the wide variety of CDs available in Japan and Hong Kong—thousands of CDs which aren't (and may never be) available here.

One of the nice aspects of this show tour is your freedom. If you want to go to the electronic shows, you'll have a bus and all the help you need. If not, there are sightseeing trips. Or you may want to go it alone. I've been going on the Commerce show tours for about eight years and find them invaluable for making contacts and keeping abreast of all electronic technologies.

The tour leaves the U.S. October 2nd from most any city you want, flying to Tokyo. You arrive the 3rd and are transferred to the New Takanawa Prince Hotel—a fine new hotel in the Shinagawa district of Tokyo. Several of us will be having dinner that first night just down the street in a great little (and surprisingly inexpensive) tempura restaurant.

The tour provides a first-class breakfast every morning—plus at least one banquet dinner per city visited. The breakfast is a fine time to meet your fellow tourers. The tour usually has between 150 and 250 people, including a dozen or more hams, so it takes a while to meet everyone.

The hotel is located right near the Shinagawa station, making it possible to get almost anywhere in Tokyo in minutes—such as Akihabara, where there are hundreds of electronics and parts stores. There's even a Baskin Robbins and a McDonalds across the street from the station, in case you get a yen for American fast food.

On the 6th we're off to Korea and the Seoul Hilton, which is near the famous Etweon shopping district. Between sightseeing (like the historical Korean Village), the electronics show and visiting electronics factories, there's plenty to do during your two days in Korea. We'll join the *73* Magazine® DXpedition group here, where their tour begins.

Next stop is Taiwan on the 9th. If you didn't get a new suit in Seoul, you'll probably buy one here. By the way, though the yen has seriously escalated in price, currencies in Korea, Taiwan, and Hong Kong have held steady, so these are still first-rate shopping countries. Tailor-made suits are around $150 here—shirts $8. They can measure you the evening you arrive, make the first fitting the next morning, and have the finished suit for you that evening.

The Taiwan electronic show is always a big one, with hundreds of small businesses showing products of interest to importers. I've been importing a bunch of computer accessories from Taiwan, so I'll be looking for new ideas.

Yes, there's sightseeing, factory visits, an incredible place called Snake Alley—but most important for me—we'll be in Taiwan on October 10th—10-10, the biggest holiday of the year—so we'll be able to visit the huge stadium and watch the kids perform. I'll have my 8mm video camera along this time and tape the whole production. You have to see the show those kids put on to believe it.

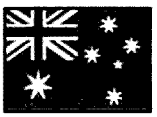
Then on to Hong Kong. Here, in addition to the fun of the city, you'll find your best shopping for cameras and electronics gadgets—plenty of record stores with wide CD selections—bargain portable CD players. If you bring along your 2m HT you can get a ticket here and operate on the seven repeaters.

There are side trips available to Macao XX, just an hour away by hydrofoil, or to Shenzhen City, for a peek into China BY.

After Hong Kong there are optional tour extensions—two days in Canton for the Canton Trade Fair, two days in Canton plus three in Beijing, where you can check out the Great Wall, the Ming Tombs, and perhaps get on the air from BY1PK, or two days in Singapore 9V1. If there's enough interest, I'll go on from Hong Kong with a small group for a short visit to the tiny countries of Sabah 9M6, Brunei V85, and Sarawak 9M8 on Borneo—an extra seven days—in case you'd like to see these fascinating, but seldom visited countries. I've been to all of them and they're well worth the trip.

How much does all this cost? The round trip economy fare from the West Coast, October 2–16th, to Japan, Korea, Taiwan, and Hong Kong, is $2,639. It's a bit more if you want to travel Executive Class—and a bit extra from the East Coast, of course.

For a full schedule of dates, costs, and details, drop me a note and I'll get 'em to you.



If you've added 8mm video to your repertoire, be sure to bring your camera and plenty of tapes on the trip. I've visited these cities a dozen times or more over the last 25 years and they're still fascinating.

You need visas to visit most of these countries. These take time to get, so you can't wait until the last minute and suddenly decide I guess I'll go on the trip. The China add-on takes even longer, with July 31st being the deadline.

About two-thirds of the people on the tour are repeat customers, so Bob Chang, the chap who runs Commerce Tours and personally conducts the tours, is doing it right.

VK6 INFORMATION

With the number of overseas visitors coming to the America's Cup Yacht Race in VK6 later this year, I have received several letters seeking information regarding amateur radio in VK6. Particularly needed was info on 2 metre and 70 cm repeater operation. I hope the following will assist these people in having an enjoyable stay in West Australia for the Cup.

Nearly all VHF-FM repeaters in Australia have a downwards shift of 600 KC [kHz] on transmit; e.g., Perth VK6RAP: receive on 146.700, transmit on 146.100. As not all repeaters are in operation at the same time, due to breakdowns or off-air being serviced (and as I am over 2,500 miles away on the other side of the continent), I cannot guarantee which ones will be working during your stay. However, here is a full list, to my knowledge, of VK6 repeater frequencies in Perth, for you to either program your sets, or bring the appropriate crystals:

RAP–146.700 (Voice)
RTH–146.750 (Voice)
RTH–146.800 (Voice)
RPD–146.950 (Voice)
REE–146.975 (Emergency)
REE–147.000 (Emergency)
RTY–147.050 (RTTY)
RWC–147.100 (Voice)

There also is one 70 cm repeater operating in the Perth area on 438.525 MHz.

PEOPLE TO CONTACT

If you wish to contact a radio club either when you arrive or beforehand, I would recommend the Perth Radio League of WA (Inc.), PO Box 106, Cannington, W.A. 6107, Australia.

As stated in previous articles, the best way to gain a reciprocal license in Australia is to apply upon arrival. In Perth the place to go is the Department of Communications, Caga Centre, 256 Adelaide Terrace, Perth 6000; Phone: 09-3255877 (within Australia).

NOTE: American Novice licenses are not recognized as valid for a reciprocal license within Australia.

The cost of a license, regardless of length of stay, is A$23. [US$1.00 about A$1.40 as of April.] If you wish to apply for a license beforehand, please write to State Manager, Department of Communications, PO Box 6189, Hay Street East, Perth 6000, Australia. All that is required is either your original amateur license (or a certified copy) to show to our D.O.C. You will then be granted a similar grade license with a VK callsign for 12 months operation within Australia.

RAOTC

In 1975, a small group of Australian amateur radio operators decided, mainly under the guidance of Bob Cunningham VK3ML, to form a Radio Amateurs' Old Timers Club, the main criterion being the holding of an amateur license for at least 25 years.

From this small beginning there are now over 750 members, with some members being classed as old old-timers, having held a license for over 50 years.

Between 1975 and 1985, club communication was via weekly on-air skeds and a newsletter. With the growing membership, it was felt an annual magazine was required to service its members. 1985 saw its inception with Max Hull VK3ZS its editor and Kevin Duff its co-editor.

The magazine itself is full of nostalgia, with listings of present members, plus later day silent keys; with the band conditions the way they are today, it is the only way some of the not-so-active old-timers get to know of a friend's passing.

The story below (by Lay VK3CF and Bill VK3CB) is typical of the magazine, and should bring back memories to some of the earlier days of amateur radio when experimentation was supreme.

The Big Re-Broadcast

During the 1928–30 period in Melbourne, when a selected number of amateur stations had permission to have "fun and games" on the broadcast band, there was much friendly rivalry between the boys to see who could come up with some novel programme to augment the playing of gramophone records.

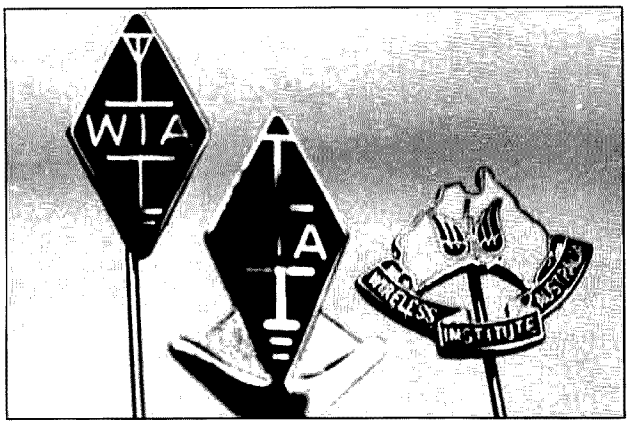
One (big deal) for those days was to re-broadcast an overseas shortwave transmission or to introduce local "live" talent from Mum's front room, using it as a sound studio with a "Reiss" carbon microphone made from a marble block carved out by the local tombstone people plus pieces of mica and lots of carbon granules. I was Bill Sievers' (VK3CB) second op—and how Mum Sievers put up with us hanging chaff bags and hessian from the picture rail right around the room to reduce reverberation (yes! we knew something about acoustics even then) and pinching the four-inch wooden curtain rings from the spare room to make our multi-strand sausage-shaped zepp aerial, I'll never know.

An amusing highlight of those days happened to the late Bert Maddick VK3EF of Elwood. He had his talking cockatoo in the shack with him, and while transmitting, the bird let loose with profanity that would have done justice to a bullock driver at his best! However, Bert was let off the hook by the Postmaster-General's Department, but only after a severe reprimand. Enough said!

One of the best outside broadcasts (O/Bs) was put on by Arthur Forecast VK3AM who arranged with his second op, Headley Myers (the "Igranic" wireless man at Noyes Bros.), to receive the powerful American station KDKA, owned by the Western Electric & Manufacturing Company, from East Pittsburg, Pennsylvania, at his QTH and then, with special permission from the Department, send their programme down the telephone line to Arthur. This was technically and otherwise very good, and it created a lot of interest until one evening the local telephone exchange operator, being unaware of the Department's OK for this activity (so what's new?) heard music on the line and immediately put on the howler which caused Arthur's many listeners to imagine that their receivers were about to blow up!

The late Stan Gadsen VK3SW, Ivor Morgan VK3DH, and the Hoist brothers, VK3BY, and many others were very active in those days, and last but by no means least, VK3CB and myself. I started out in the "OA prefix" days (prior to the VK prefix) as Bill's second op.

Not to be outdone by the aforementioned weekend amateur broadcasts, we let it be known one weekend that on the following Sunday night at 11 p.m. we would re-broadcast a programme from JOAK, Japan. This station could be heard on the BC band on a slightly higher frequency than 3LO when the latter closed down at 10:30 p.m., as did all the BC stations in those days.



Normally we could receive JOAK at good strength at East Richmond, but on the Saturday night prior to our much publicized "Big Re-Broadcast," my multi-tube receiver packed up and in no way could it be fixed up in time for the following night's "do." After the first wave of panic subsided, we dreamed up an idea to get us off the hook: in fact it was a stroke of genius! We announced on the Saturday that due to matters beyond our control, we could not relay the Japanese station but, as an alternative, we would do a re-broadcast from China and thus keep faith with our listeners who were patiently waiting for the overseas broadcast.

Bill and I now applied our true amateur talents! We had no idea at all of the existence of a Chinese broadcasting station, so we created one ourselves! Firstly, Bill managed to fit a switch which would reverse the direction of rotation of our gramophone motor while I arranged our Webster pickup arm to track from the inside out. We then drilled a new spindle hole about 3/4" off centre in an old 10" disc on which was recorded mainly voice. This was placed on the turntable using the off-centre position for the spindle and, after the big announcement of the "Big Re-Broadcast" from China, the thing was played off-centre, inside out, and back to front!! Talk about a Chinese broadcast; it was perfect! The secret of a nonexistent foreign broadcast has remained with us. . . until now!

I am grateful to VK3CF and VK3CB for the above story!

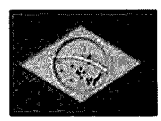
WIA BADGES

For nearly half a century or more, the WIA has had the same lapel badge featuring Australia over a banner of the WIA, but with the ease of international travel, some of the members voiced a need for an international-type lapel badge, with the familiar diamond shape being mooted. This

The Australian badges. L to R, new, newer, and old.

diamond-type badge was manufactured, with quite a few being bought by members.

This, of course, brought howls of indignation from some older members saying, "We are losing our National identity!" The arguments raged back and forth, with the result being that a third badge was made featuring the diamond shape plus a boomerang. The idea being that the diamond was for easy international recognition and the boomerang depicting Australia, with the added bonus that it was simple matter to have your callsign inscribed upon the boomerang; this badge would serve a three-fold purpose.



The arguments are still going strong with some members, as to which badge is the most representative of the Australian amateur. Photos of the three badges are included to help you form your own opinion!

SPICE UP YOUR QSO WITH PHRASE DROPPERS

Ever noticed how your QSO becomes a little light on technical conversation? Well, try a few of the combinations in Fig. 1 next time and no one will ever admit that they don't know what you are talking about! Select any three of the phrases, such as 3, 7, and 9, which give "parallel incremental consistency." Maybe your transceiver just fits the bill.

0. integrated	0. muted	0. options
1. total	1. organizational	1. flexibility
2. systematized	2. monitored	2. capability
3. parallel	3. reciprocal	3. mobility
4. functional	4. digital	4. programming
5. responsive	5. reactive	5. concept
6. optional	6. transitional	6. time phase
7. synchronized	7. incremental	7. projections
8. compatible	8. overtone	8. hardware
9. balanced	9. emissional	9. consistency

Fig. 1. An extract from the VK2 Westlakes Amateur Radio Club's Monthly Newsletter, April, 1982.

BRAZIL

Carlos Vianne Carneiro PY1CC
Rua Afonso Pena 49/701
20270 Rio de Janeiro, RJ
Brazil

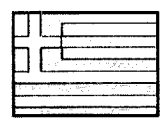
WWSA CW 1986

Last year's changes in rules for the World Wide South American CW Contest brought very interesting consequences and results—a strong increase in participants being the immediate response. (See "Contests" in this issue.) Simplified purpose, contacts between stations in all countries, seems to be the best to everybody, considering we had almost double the radio amateurs from all parts in 1985.

As contest period annually is every second complete weekend of June, from 1500 UTC Saturday to 1500 UTC Sunday, this 1986 it starts June 14. Keep an eye on that second and complete weekend! Bands are 1.8, 3.5, 7, 14, 21, 28 MHz, and crossband contacts are not valid .

Classifications—2-way CW mode, only for (1) single operator, single band or all bands, (2) multi-operator, single transmitter, all bands, (3) SWL. Call will be—CQ SA TEST.

Exchange—RST/QSO number starting from 001.



Points—Each QSO in same country 0 points (valid only as multiplier); in same continent, two points; in other continents, four points. Only for DX stations, QSO with South American stations, eight points!

Multipliers—all different countries (DXCC list) and different South American prefixes worked in each band.

Scoring—final score is the total QSO points multiplied by the sum of total multipliers from all bands.

Certificates will be granted to three top-scoring stations of each class in country, reasonable score provided. Results of South American entries will be listed separately from other continents.

A separate log for each worked band must be sent not later than August 31, 1986, and PSE follow standard international contest logging rules! Send to WWSA Contest Committee, PO Box 18003, Rio de Janeiro, RJ, Brazil 20772.

GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

In one of my previous columns I had mention about a new repeater (RØ) on top of Taigetos Mountain, and I promised to return to it with more details. The reason is this is the first Greek repeater under solar power and also under remote control. Of course this might look like a common situation for countries with a lot of amateur population, but for our country I shall call the event as unique.

The man behind this installation was John SV1KC, an excellent electronics engineer who has put all of his talent on writing the software but also designing and building the hardware for the control of the repeater.

The repeater's site is on a place called Ag. Panteleimonas, 1640 meters above sea level in South Peloponese. Because of the high altitude, several parameters had to be met before everything was ready for the top.

Now what the hardware contained was a Yaesu receiver and transmitter, an RX-TX systems duplexer, a colinear heavy-duty antenna with four dipoles, three starved electrolyte batteries, and three photovoltaic panels from B.P. (British Petroleum). The repeater was designed with two power levels (2.8 and 8 W), and every two hours is giving telemetry with information about its status.

The full message is transmitted every two hours and looks like this: VVV CQ CQ DE SV3A ...CHRG...AH DICH...AH TEM IN...DEG TEM OUT ...DEG BAT CAP...AH AR.

CHRG gives charging current for the last two hours, DICH gives power consumption during the past two hours, TEM IN gives inside temperature, TEM OUT gives outside temperature, and finally BAT CAP gives battery capacity. Along with each transmission RØ sends a subcarrier of 72.8 Hz for monitoring service.

The receiver consumes only 14 mA squelched, and power output is dependent on the capacity of the batteries (more on this later). Both receiver and transmitter are using ovens for the crystal oscillator in order to keep temperature between 25–30 C. There is also a clever system into the receiver called "economizer" (Yaesu uses this in FT-209 handheld). With this system, the receiver if is not triggered for 10 seconds then goes to 9% duty cycle receive (90% off and 10% on) preventing spending energy for no reason.

I think that this is enough for the hard part of the repeater. In my next column I will look a little more inside SV3A's logic and will reveal all the power that a soft control can give to an ordinary repeater.

HONG KONG

P. J. Weaver VS6CT
10A Bonaventure House
91 Leighton Road
Hong Kong

I am scheduled to leave here on May 12 for my triannual leave and will be visiting with friends in Cali-

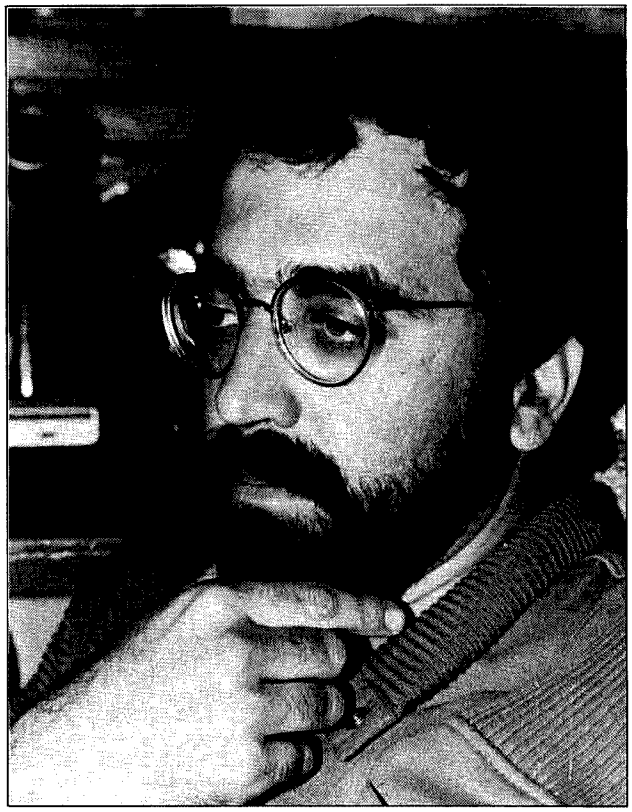
fornia, Oregon, and Illinois until June 15. Then I head for Miami and hope to join a 48' DeFever motor cruiser for a six-week cruise around the Bahamas and Exumas Islands. Subject to confirmation, I then hope to spend August in the U.S. Virgin Islands, perhaps operating as VS6CT/KP2, which will be bound to attract some attention! I will then be in the New York area for a week or two before going on to England in mid-September. I am due to return to start work here on October 15.

I had a most interesting five-day trip to Okinawa to visit the Western Pacific Search and Rescue Center. It was mainly a familiarization trip to learn how the other half operated, as we work very closely with that organization when there are any search-and-rescue operations going on in our region. Another seminar in Singapore in April is being put on by the International Maritime organization, but we will have to sing for our supper there. I am busy now preparing a paper to present, on how we do our search-and-rescue operations here, and the facilities we have. After Japan and Okinawa, Hong Kong is considered the most effective operation in the far east, and we have been asked to show other ASEAN country representatives how we do it.

Amateur radio in Hong Kong is making very big strides at this time. At the moment, we have over 300 licensees of whom over 70% have the Class B license—they have passed the technical exam but did not have to take code. They are permitted to operate on 30 MHz and above, and of course that includes satellite operation. They are a very keen bunch, and since we implemented this license (for which I was responsible for achieving), there has been great interest among the local Chinese. Thanks to this no-code licensing, which is the same as in the United Kingdom, with the same exam, we have had a big expansion in activity. By October I hope we will have four more repeaters to add to our present three, and a closed repeater for the English-speaking hams only. One of our major problems with the increased activity is that repeater chatter is all in Chinese, and as an English-speaker only, I can do a lot better if I don't have to listen to a repeater pouring out a language I don't understand.

Had great fun over the Chinese New Year holiday in February, doing one of my expeditions to Macau. I made 2,700 contacts, well short of my average, but conditions were not the best, as was to be expected at the bottom of the current cycle. Expeditions to Macau are becoming more and more complicated, however. In the good old days, it was a matter of simply applying for a reciprocal license and getting on the air, either from an existing station which one had on loan or setting up in a hotel. The fee was US$3.50. Now it is US$17.50, plus US$25 if you ask the Post Office to do all the forms for you, on the ubiquitous Portuguese "Blue Paper," which is used for all legal matters. The license is valid for only 30 days, and after setting up your station you have to have it inspected before you can operate. All this has happened just recently; and I don't think I'll bother with Macau again, at least not unless I can use an existing station.

My best to Wayne. It will be delightful to read his editorials again and I am delighted he is back at the helm of *73*. I hope you will consider publishing short stories again from time to time. I have been amused by them in the past. Perhaps you could ask subscribers to contribute some which have a "ham flavor."



ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev M.P.O. 85530
Israel

An important precedent for amateur radio has been set in the Haifa City Court. Until recently, antenna lawsuits were troubles only to be read about in the American ham press, as far as Israeli amateurs were concerned. Now, after a short but tense court case, the hams here can breathe a sigh of relief, thanks to the refusal of Israel Lavie 4X4UF to bow to the pressure of his neighbours.

To supply necessary background, most Israelis do not live in detached houses, but dwell in apartment blocks which are the common property of the dwellers, each person owning his own apartment. The denizens elect a "house committee" which is responsible for the upkeep of the building, collects maintenance fees, and makes rules regarding the use of the common property.

Dov Gavish 4Z4DX.

A few years ago, 4X4UF, a ham of more than twenty years seniority and known in the amateur community for his technical innovations and construction of miniaturized transceivers, moved from the Galilee town of Carmiel to the city of Haifa. Not a big DXer, he satisfied himself with a modest dipole antenna on his building's roof. I suspect that most of his operating anyway was on two meters while driving to and from work.

One bright day, the house committee of his building decided that the black coaxial cable coming down the side of the building to Israel's window from his dipole was an eyesore, and demanded that he remove it. Gritting his teeth, as it were, Israel complied, but in order to partly compensate himself he installed a small two-meter beam attached to the railing of his balcony facing out from the back of the building.

Ancient Hebrew proverb says, "You give them a finger and they take the whole hand." One day 4X4UF opens his mailbox and finds himself served with a summons to appear in the Haifa municipal court, charged with defacing the appearance of the building. In the meantime, he removes the beam but photographs it for posterity.

Hiring a lawyer and accompanied by a few amateurs as witnesses, Israel appears in court and presents the photograph as evidence. The chief municipal building inspector says that to his recollection the antenna on the balcony was bigger, so the court adjourns so that the actual antenna in question could be examined.

In the course of the examination, it becomes clear that said antenna was not permanently attached to the building; it looks like that on these grounds Israel may get off the hook. However, in this case the right of the ham to his antenna will still be in question, and red-head 4X4UF, once challenged, does not back off.

There is no substitute for a smart lawyer, and, indeed, Israel's has been doing his homework. Checking the conditions of the license, the lawyer discovers that section 13 article 4 of the Israeli Amateur Radio License contains the following (which I have translated from the Hebrew):

"When there is, in the opinion of the Minister of Communications, a state of emergency, and the public welfare deems it neces-

sary, the director [of the Ministry of Communications] will be authorized to take charge of the station, to supervise it or use it for the needs of the State, without payment, or to transfer it to whom he sees fit, or to order the owner of the license to operate the station according to his instruction. The duration of this clause will not expire with the cancellation, correction or change of the license."

Armed with this important yet generally overlooked section of the license, Israel's lawyer, taking a more offensive posture, asks the judge, how, in the time of national emergency, can a radio amateur comply with the terms of his license and be of service to his country if his station has been rendered ineffective by the lack of an antenna? Indeed, in such times, the ham station is not an individual's means of personal entertainment, but a vital resource determined by law to be put at the nation's disposal.

It should be pointed out that this case took place when the memory of the vital service provided by amateurs at the time of the Mexican earthquake disaster was still fresh in the public consciousness, and, coupled with a year of excellent media coverage, amateur radio in Israel was riding on high waves of popularity.

Upon hearing this argument, the judge was convinced and the case standing against 4X4UF was dismissed. The amateurs Israel had brought to court did not even have to testify, and similar charges that were standing against another Haifa amateur were dropped.

What is the significance of this court decision for the Israeli radio amateur? This case was fought in a municipal court, so although directly affecting only the city of Haifa, should the right of an amateur be contested in other courts, an important precedent has been set.

In Haifa, any licensed radio amateur can erect an antenna on the premises whose address appears on his station license. A transmitting antenna does not require a building permit, and the Haifa chief building inspector has said that should he receive any further complaints, he will first consult with officials of the Israel Amateur Radio Club before deciding whether action should be taken.

Compared to the costs of similar legal struggles abroad, this case was a bargain, with legal fees costing $500. The Israel Amateur Radio Club put up $150 aid, and it is expected that Israel will receive enough donations so as not to feel any monetary pinch.

It is our hope that this will be the end of legal proceedings against ham antennas, and, naturally, a wish goes out from here that all amateurs worldwide will be able to defend their antenna rights with such relative ease.

At the time of writing Israel Lavie is not celebrating his victory with a monstrous multi-element tribander perched on his building's roof. However, his modest two-meter beam is no longer on the balcony railing but is on top of the building, and when he does manage to get on two meters, I'm told that his signal has never been better.

A TOP DXER

4Z4DX

One of the few Israeli amateurs to climb close to the pinnacle of the coveted DXCC honor roll is Dov Gavish 4Z4DX, who to date has confirmed 315 of the current 316 countries.

Brought up on amateur radio on Kibbutz Ramat David in the northern Jezreel Valley, Dov is the son of the late Israel Gavish 4X4VB, who passed away last year. With his wife, Anat, and two children, Dov today lives in Ramat HaSharon, ten miles north of Tel Aviv.

His back yard has turned into an antenna testing field, where it would seem that nothing less than a *very* thorough testing suffices. This is evidenced by having achieved on *five* bands, Worked All Zones (first in Israel), DXCC, and Worked All States—not a simple task from Israel. Other certificates earned are 160-meter DXCC, YL DXCC, Worked All German Countries, and 2500 U.S. counties certified in the County Award.

Inside his shack sit the Kenwood TS-930 and Drake TR4 plus the Robot slow-scan television outfit. The current antenna farm consists of a KLM 6-element tribander at 95 feet up, a 2-element 40-meter beam, and full-sized slopers and inverted vees for 80 and 160 meters. In the past he has tried different antennas for 80 and 40—delta loops, wire beams, slopers, and even a rhombic that he once stretched between four irrigation pipes on a once-vacant field adjoining his house.

Dov is also active in group activities, having found the club station 4Z4EX in Ramat HaSharon and organized the 4X6A multi-multi operation that took first Asia in the 1979 CQ World-Wide DX contest in SSB in which your faithful scribe had the honor to participate.

What's Dov's secret? If he has something special he isn't saying, but there's no doubt that the key is perseverance—listening on the bands with great concentration—good antennas, and a certain sixth sense that every serious DXer seems to develop.

NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

RECIPROCAL LICENSING

Over the past year or so I have had a few enquiries from amateurs who intend to visit New Zealand regarding our reciprocal licensing arrangements. For those who may be interested I shall outline them again, more fully than on the last occasion.

Countries with reciprocal agreements with the New Zealand Government include Sweden, Switzerland, French Republic, United States of America, and the Netherlands. In addition, countries with Commonwealth recognition Include Australia, Canada, and the United Kingdom as well as a large number of Commonwealth and Pacific countries; countries with guest licenses include South Africa.

NZART, recognising the importance of this facet of our hobby, have appointed Russ Garlick ZL3AAA co-ordinator of the Reciprocal Licencing Bureau, and any enquiries regarding reciprocal licensing may be directed to him. He also keeps up with the information ZL amateurs need to know when they contemplate an overseas trip. The address for Russ is: Mr. R. A. Garlick ZL3AAA, 23 Lydia Street, Greymouth, New Zealand.

Here is a guide to the requirements for an application for a reciprocal license when visiting New Zealand:

1. Complete an application form in duplicate (obtainable from Russ or the Radio Regulatory Section, Post Office Headquarters, Wellington, New Zealand).

2. Supply with the application a photocopy of your operator's certificate and a copy of your current receipt for annual fee paid.

3. A certificate to indicate the Morse speed at which the applicant is qualified.

4. If no evidence of Morse speed can be submitted, the applicant may sit for the examination in the normal way. (Remember, ZL VHF operation is with a non-Morse certificate, so if you only want 2m or 70cm operation, this condition is not important.)

5. A birth certificate or evidence of the date of birth, e.g., a copy of driver's license if date of birth is shown on it.

6. Applicant must submit a permanent postal address to where all correspondence can be sent (consulate, travel agent, etc.).

7. All applicants for a license must give *at least two weeks notice* before license application can be processed.

8. License applications can be made to the Radio Licencing Section, Post Office, of any of the 17 main cities or to Radio Regulatory Section, Post Office Headquarters, Wellington. It is recommended that you send your application to the Radio Licencing Section, Post Office Engineers Office, at your point of entry, or to Post Office Headquarters, Wellington.

9. Visiting amateurs will be allocated a callsign from the ZL0 series.

10. There is no charge for the service.

While on the subject of reciprocal licenses, I have nothing but praise for the FCC in the States and for the Department of Communications, Vancouver, Canada, for the prompt attention to my applications for reciprocal licenses to use on my visit to USA and Canada in May through to July this year. I made the usual applications for the licenses early in January, and one month later I had received both reciprocal licenses, well before my projected departure date.

We will have three weeks on a Friendship Force holiday at Kauai, Hawaii, Spokane, Washington, and the Seattle area, and after that period we will be proceeding on an independent couple of month's holidaying in Canada and the States. I shall be looking forward to many QSOs on 2m as we travel around with the 2m handheld, and also some HF QSOs on the HF bands while visit-

ing at Port Coquitlam, near Vancouver, mid-May to mid-June, where through the courtesy of my host, Jack VE7CMD, I hope to have the use of his HF gear. Listen out for ZL/VE7 portable about that time as I will be looking forward to QSOs with those who read this column.

I shall also be visiting amateur friends in Charleston, West Virginia, Buffalo and Amsterdam, New York, Peterborough, New Hampshire, Hartford, Connecticut, and Prince Edward Island, Canada, in the later part of June and early July.

Visiting amateur radio operators with whom you have already made contact is the fulfillment of the friendship begun on the air, and something I can well and worthily recommend to those who are able to travel overseas. I have had endless hours of pleasure from such experiences; in fact, this will be my third visit to Port Coquitlam in ten years, with many pleasant QSOs in between times.

IARU CONFERENCE "SHORTS"

All but four of the delegates took advantage of the visitors' license ZL0-series offer, and those who had sent license details in advance were given their ZL licenses and a supply of preprinted QSL cards on arrival.

There was an interesting sidelight to that too: All the Indonesian delegation joined NZART. When asked why, they said, "We have a ZL call, therefore we must join your society." Wouldn't this be a marvelous attitude to apply everywhere! It would make our amateur organizations much stronger numerically than we are now—with only about half the licensed amateurs being members of their national societies.

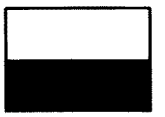
The ZM6ARU station and the Conference Award generated a lot of interest worldwide—in all, some 2500 cards, including 120 OSCAR-10 QSOs were dispatched through the bureau.

Bob Holt ZL1BBZ, the mini-bus driver for the ladies, took a week's leave to be amongst those lovely ladies—he ran up well over 2000 km during the period of the Conference chauffeuring the ladies around on their sight-seeing trips. The success of the ladies' programme was summed up by a delegate saying he did not have to worry about his wife during the day and she was too tired to want to go out at night!

SILENT KEY

Mrs. Myrtle England ZL4GR passed away on 31 January, 1986, just six days short of completing 56 years as a licensed amateur. "Myrt," as she was known on the air, was New Zealand's first licensed woman amateur radio operator, receiving her license on 6 February, 1930. She was honored at the 1980 NZART Conference when she was awarded WARO's (Womens' Amateur Radio Operators) first 50-year Certificate and elected an Honorary Life Member of that organization. Myrt was active in local and DX operating—she operated as a relay station during the Napier earthquake in 1931, a base station during snow-storm isolation, and a valuable aid in Search and Rescue over many years.

Myrt's friendly voice on the air has been stilled now, but she will long be remembered for her distinctive personality, her vitality and enthusiasm, and above all, her wit and humor which many shared with her at Association Conferences and other amateur gatherings.



REGION III AWARD

Eligible countries are those in Region III whose amateur radio societies are members of the IARU Region III Association. These are Australia, Brunei, Bangladesh, China(PRC), Fiji, French Polynesia (FO8 only), Hong Kong, India, Indonesia, Japan, Korea, Malaysia, New Zealand, Pakistan, Papua New Guinea, Philippines, Singapore, Solomon Islands, Sri Lanka, Thailand, Tonga, and Vanuatu.

Plus one country credit from U.S. Territories in the Pacific, from Guam, Northern Marianas, American Samoa, Wake Island, Baker Howland Group, as represented by ARRL; one country credit from Pitcairn Island (VR6), Chagos Arch (VQ9), represented by RSGB. (Current total of available "countries" is 24; requirements for award as *from 1 January, 1986*: Basic—7 areas; Silver endorsement—15 areas; Gold endorsement—20 areas.

These to be reviewed as considered necessary by the Custodian, Jock ZL2GX, who will recommend appropriately to the Region III Secretariat.

Applications to NZART Awards Manager, ZL2GX, 152 Lytton Road, Gisborne, New Zealand, with NZ$1.00; if airmail postage required, add another NZ$1.00 extra. IRCs are acceptable.

POLAND

Jerzy Szymczak
78-200 Bialogard
Buczka 2/3
Poland

Many Polish scouts took part in the annual scout's jamboree on amateur bands. Participation in this fixture, serving for a consolidation of friendship among nations, will be rewarded with occasional diplomas issued by International Scouts Bureau in Geneva.

On July 20th and 21st, a meeting of members and friends of hams took place in Jaroslaw. 60 girls—radio amateurs—came to the meeting. An all-Polish Club of Women Radio Amateurs was formed. Zofia SP8LNO was elected the president and Maria SP8OBF the secretary of the "Club YLSP." The secretariat of the club announced that every 21st day of months is a women's-activity day. The club station uses the callsign SP0PYL.

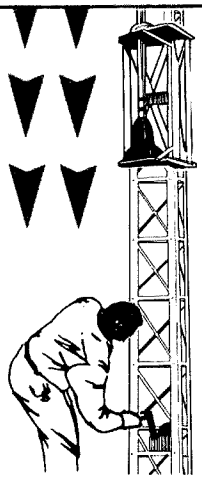
On the occasion of International Telecommunication Day in May, occasional radio station SP0ITU worked on the amateur bands from 10 till 19 May last year. The radio station consisted of transceiver FT-101ZD of shortwave bands, transverter 144 MHz, radio-telephone FM306 on UHF, and antennas: dipole, inverted V, vertical 14AVQ for 7, 14, 21, 28 MHz bands. During 9 days of activity, 2821 QSOs of 92 countries and 28 WAZ zones were established. Most of the contacts were gained on the 20m band.

On October 5th and 6th last year a Convention of Radio Amateurs Railwaymen was held in Moszczenica. Dozens of hams took part in the convention under the slogan: " Railwaymen hams—boosters of technological education of society." The president of PRAA, Jerzy Rutkowski SP5JR, attending the convention, suggested a modification of the name to Polish Radio Amateur's Club Railwaymen. In consequence of a ballot, the first management of PRACR was set up. The function of the president of the club went to Henryk Paszkowski SP5HP, the vice-president, Ryszard Jablonowski SP9EES, and the secretary, Miroslawa Paszkowska SP5MHP.

The residence of the club is situated at Varsovian Communication Club "Kolejarz" Hoza 63/65 Warsaw. After the approving of the working programme, Adam Koziarski SP5AY, the author of the modification, gave a lecture on an adaptation of the radio-telephone FM-302 for a SW transceiver. An occasional radio station SP5PKP/7 began its activity on the eve of the Convention.

On the occasion of 40 anniversary of the end of the Second World War, PRAA instituted a diploma "Forty years anniversary of Victory and Peace". To win the diploma a radio amateur had to establish contacts with at least one of 38 ham veterans of the Second World War. The veterans' callsigns were "broken" with V (Victory). Mainly for good reasons, only 28 radio stations of veterans were active to 9 May 1985. Nevertheless, many Polish and foreign radio amateurs won the diplomas.

SPAIN



Domingo Gil Manrique EA5TX
Delegation Local de U.R.E.
Avd. La Mura 67
12540 Villarreal (Castellon)
Spain

The Spanish Radioamateurs Union (U.R.E.), through its local group in Villarreal, has established the TD-EA-CW Award, available to any ham or SWL with an official license granted by any IARU member country.

A two-way confirmed contact, direct, must be made with each of the nine EA districts over any period of time since January 1, 1976. CW only, over authorized amateur HF bands, and all must be made from the same DXCC country using the same callsign. Not valid: contacts through repeaters, satellites or similar means of communication, and mobile contacts.

Endorsement stickers: 5B (nine districts times 5 bands—45 contacts), and 160 (nine districts on the 160-meter band). Decisions of the Award Committee shall be final.

Send verified log and US$3 or the equivalent in marks, pounds, or IRCs to the Awards Committee (TD-EA-CW) at the above address for the 5-color award on heavy paper, 46 x 34 cm.■

SAVE TIME and MONEY with THE HAZER

Bring things down for safety and convenience.

Never climb your tower again with this elevator system. Antennas and rotator mount on HAZER, complete system trams tower in verticle upright position. Safety lock system operates while raising or lowering. Never can fall.

Complete kit includes winch, 100 ft. of cable, hardware and instructions. For Rohn 20 and 25 G Towers.

Hazer 2 - Heavy duty alum. 12 sq. ft. load	**$297.00 ppd.**
Hazer 3 - Standard alum. 8 sq. ft. load	**$213.00 ppd.**
Hazer 4 - Heavy galv. steel 16 sq. ft. load	**$278.00 ppd.**
Ball Thrust bearing TB-25 for any of above	**$42.50 ppd.**

Martin also mfgs. aluminum towers specifically engineered for use with the HAZER. Two sizes - M-13 (13" wide) and M-18 (18" wide). Also a truly self-supporting galvanized steel tower. Send for free details.

Satisfaction guaranteed. Call today and charge to Visa, MasterCharge or mail check or money order.

HAM HELP

I'm looking for manuals for the following equipment: Topaz model 2LRA117SN anti-brownout ac line regulator, Motorola model XT1034C/T1034C rf signal generator, Plessey model MRA101 Tellurometer, Motorola HT-200 low-band walkie-talkie, Supercall model 6080KM mobile telephone, and the following CB radios: Claricon Raider, JIL model 615CB, RCA model CRM-P3A-5, Radio Phone Mark VII, Lloyd models A-400 and A-410, Kraco KCB-2340, Pace 8015, Pony 40, Hy-Gain 9 model 2679A, Hy-Gain 7 model 3107, President John Q, Cobra 19 and 21 XLR, Johnson 123-SJ, Midland 13-884, Spitfire Mark II, Royce 1-648, Ross CB-1000, Fanon Convoy PLLF, Prominent PT-23, Pony model CD-705S, Beltek Rough Rider model W5396, Fanon Fanfare 330 Convoy (23 channels), Fanon Courier Classic III, and Beltek W-1326F.

I also need CB Photofacts; a service manual for a Pace Base Command model P-5407 dummy load/wattmeter/swr meter; service manuals for Yaesu models FTC-2203, FTC-2205, and FTC-2640; back issues of *CB, S9, Canadian Transceiver*, and any others; NRI/McGraw Hill VCR servicing courses; and a service manual for a Hamlin MLD-1200-3.

Rejean Mathieu VE2EUI
1897 3rd Avenue
Val D'Or Quebec J9P 4N7

I am looking for a schematic and a manual for the Harvey Wells Bandmaster Senior model TBS-50C transmitter and power supply. I will pay for copying or will buy them—whichever you like.

Charles E. Phillips WB8AGB
402 Wickshire Lane
Durand MI 48429

Does W6RO aboard the Queen Mary QSL? I worked them in June, 1985, and so far, through mid-January, three cards, complete with SASEs, have gone unanswered.

Also, I'm trying to locate a source for 36-mm vernier dials to replace those on a home-brew antenna tuner I bought. The vernier shafts extend 1/2" behind the panel, and the two mounting screw holes measure 1-1/4" center to center.

Last, but not least, where can I obtain a male plug for the user port on a Commodore 64 computer? It has a protective shell and a strain relief to prevent possible shorting of the contacts. The one included with my Kantronics Packet Communicator doesn't have the shell, and I'm worried about possibly shorting something out, damaging the computer and the TNC.

Gary Payne KE6CZ
1347 E. Dakota
Fresno CA 93704

I need NAVSHIPS 91713, 93241, and 93788 Volumes 2 and 3.

C. T. Huth

ISSUE #310 JULY 1986

Focus On Clubs

How To Build A Great Ham Club 26

Not only is this the first article in this month's issue (not, of course, because it was written by the Boss), it sets the theme for our focus on clubs. Why are so many clubs going down the tubes? What can be done to increase the level of enthusiasm in yours? There's no sure-fire formula for success, but there are a few key concepts that must be understood before a club will really take off. Here are those concepts.

Bozo and the B-Hunt 36

No, not the clown. We can't tell you what this article is about without giving away the punch line, so let's just say that your club's repeater might be the prime ingredient in an insanely fun club activity! (For those of you who can't wait to get to page 36, here's a clue: *The music stopped, the lady died.*)

HAMS Against Drunk Driving 38

It stands for the Highway Amateur Monitoring System, a program designed to involve ham clubs in the fight against drunk driving. You certainly can't get any more public-service oriented than that. Use the ideas presented here to form a HAMS unit in your home town.

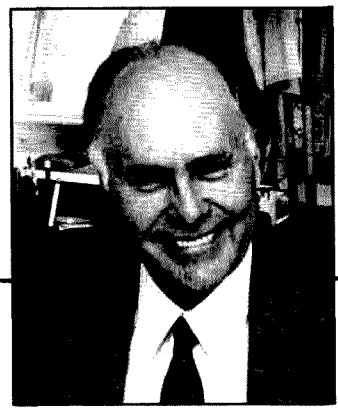
Future Hams of America 44

This is an example of what a club can do when *everybody* pitches in! The Council of Eastern Massachusetts Amateur Radio Clubs (CMARC) wouldn't settle for a ho-hum mall demonstration: They invaded the Boston Museum of Science and introduced 8,000 people to the excitement of ham radio! Here's how they did it, and how *your* club can do it, too!

Publish Or Perish 48

Look, we read about 150 club newsletters every month as part of *73*'s Newsletter of the Month contest. Believe it, if your club publishes a newsletter, you need to read this piece by N1BLH. In it you'll discover what makes a great newsletter great, where to get material, what sort of layout to use . . . in short, everything that you need to know to publish a dynamite newsletter. (Past winners of the NOTM award may skip to the next article.)

Introducing: Kit Corner



The DSE Radio Direction Finder 64

We're trying something new here, a cross between a construction article and a review. The idea is to introduce you to all of the various kits that you can build, with the hope that you will start building them. Dick Smith's RDF is a clever little gizmo which electronically rotates four whips at 1,250 rpm to determine the bearing to a transmitter; the bearing is displayed on a 32-LED compass rose.

All rights reserved. No part of this publication may be reprinted or otherwise reproduced without written permission from the publisher. Microfilm Edition—University Microfilm, Ann Arbor MI 48106. **Postmaster:** Send address changes to *73 Amateur Radio*, Subscription Services, PO Box 931, Farmingdale NY 11737. Nationally distributed by International Circulation Distributors. **Contract Liability:** The mere glancing at this binding reader contract constitutes total acceptance on your part of the contract provisions and terms hereunto enumerated. Too bad if you looked. Read this out loud: "I do hereby swear that I will be a true and loyal subscriber to *73* Magazine—that I will, without failure, diligently mark the Reader Service card indicating the information I need to improve my station—that upon receiving the requested information I will select and order the equipment I need to pursue a new facet of my beloved hobby—further, recognizing my egregious faults, I agree to turn over a new leaf and become a much better amateur operator." The above is binding even if spoken sotto voce—I saw you move your lips, so no weaseling out. By the way, you mispronounced "egregious." Can't you do anything right? Atone. A simple abject apology on the border of the Reader Service card will suffice. This'll teach you to read the fine print.

NEVER SAY DIE

WHY WEREN'T YOU THERE?

Just about everyone in amateur radio who's been doing anything more than rag-chewing what's left of their lives away turned out for Dayton again this year. It was mobbed, as usual.

No matter how many cavernous buildings they add to the Hara Arena, the manufacturers and ham dealers seem able to fill 'em up. One reason for the action is the whipsawing of dealers by hordes of unscrupulous hams dashing back and forth, getting ever lower ham gear prices. Dealers are faced with the choice of making a dollar or two or not making the sale. The prospect of packing up all that stuff and trucking it back to the store a couple states away eventually makes even a small loss on the sale attractive.

One result of this has been the gradual disappearance of many larger ham dealers as exhibitors.

Our hobby, as you know, is in reality a whole bunch of related hobbies. . . DXing, packet, repeaters, meteor scatter, moonbounce, service nets, QRP, certificate hunting, SSTV, RTTY, and so on. Dayton has become the mecca for these ham splinter hobbies—a place where the annointed are able to get together every year and outlie each other.

It's also heaven for the dedicated scrounger. The flea market area sells out completely—acres of surplus equipment going back at least to WWII. Come to think of it, the surplus WWI gear seems to have stopped showing up. When I was getting started in the hobby the surplus stores on Canal Street in New York still had piles of WWI radio surplus.

I wandered out into the flea market with an idea of awarding a prize for the most useless piece of junk I could find. In no time I had so many top contenders for the award I had to give it up. I did note a definite drop in Heath Twoers on display, thank heavens.

I would like to personally thank everyone who took the time to stop at the *73* booth and say hello, wishing me luck with the magazine. My apologies to the several thousand more who missed me while I was seeing the other exhibits.

One thing really worries me though. Unless we have some success in getting our hobby growing again—which depends entirely on YOU—we're looking at a rapidly shrinking hobby. This means that unless you take very good care of yourself, we're going to run out of hams. I was dismayed at the number of you I saw who are recklessly ruining your most important possession—your body. Lordy, I saw great big fat guts hanging out all over the place—beer bellies by the thousands. Many hams, knowing my feelings about smoking, put 'em out before saying hello. But I want you to know I was out there watching you. . . I saw you light up again after leaving my booth. Do you really need someone to hit you over the head to get you to make up your mind to stop smoking?

You know as well as I do that smoking is killing you, slowly but surely. It's working on you, preparing you for heart trouble, cancer, emphysema, and dozens of other exceedingly painful slow-death illnesses. My father smoked for fifty years, swearing nothing would ever make him stop. When he began passing out now and then he sure stopped—and lived on twenty years more. But the last few years were hell. His emphysema got so bad he couldn't breathe without an oxygen tank. He couldn't walk more than a few feet, even with oxygen. It's something to think about as you reflexively pull out another cigarette and light up.

Of course if you don't mind giving up about ten years of your life for the pleasure of smoking. . .

Repeater Rules

THE FCC has taken positive action in the matter of repeater frequency coordination. In a final ruling on PR Docket 85-22, the Commission recognized the need for frequency coordination and included a definition of a frequency coordinator in Part 97. In cases of co-channel interference, the new rule stipulates that a non-coordinated repeater has the primary responsibility for resolving the problem. The rule does *not* make coordination mandatory, so repeater owners in less populous areas can continue to operate without a coordination council. Also note that owners of coordinated repeaters are not absolved of blame in interference cases . . . the rule is not intended to be used as a tool to force machines off the air. WA6ITF has the complete rundown in Looking West this month, beginning on page 87.

Canadian Setback

JACK RAVENSCROFT VE3SR has lost his case. Jack was sued by Tim and Dale Houghtby, who claimed that Jack's transmissions interfered with their electronic organ, their microwave oven, their furnace, and just about everything else electronic in the Houghtby house. The Canadian DOC examined the ham station and pronounced it clean. The judge, however, found that Ravenscroft's transmissions were a nuisance and issued an injunction forbidding Jack from transmitting from his house in any way that would interfere with electronic equipment owned by the Houghtbys. In addition, Jack was ordered to pay an award of just over $2,500 plus court costs. The decision sets a terrible precedent. WA6ITF, writing in the *Westlink Report*, says that some Canadian amateurs intend to force the government to step in and reverse the ruling by bringing a massive suit against a major Canadian broadcast company, claiming it to be a public nuisance.

Dayton Dossier

THE DAYTON HAMVENTION was incredible! This year's crowd was the largest ever, with 28,000 glassy-eyed hams tearing around deep in the throes of a spending frenzy. Most conspicuous were the dozen or so dealers selling IBM PC clones, all of them of course "99% compatible," whatever that means! Every day at Dayton held a special surprise. On Friday, some idiot tossed a stink bomb between the ICOM and the Kenwood booths in the main arena. On Saturday, an extension cord overheated and smoke filled the large ballroom; and the place was evacuated for about 30 minutes while the fire rescue team checked things out. (I'd like to congratulate the Hamvention security team on a very professional evacuation.) On Sunday, the main arena was plunged into darkness for nearly four hours when a pole pig roasted itself. Predictably, the darkness did not deter anyone from browsing, and it was nearly business as usual with the aid of flashlights (a booth in the arena was selling them for a dollar). Luckily, the lights came back on before the giant prize drawing on Sunday afternoon. Business was brisk all three days, and the weather was absolutely perfect over the entire weekend.

Lots O' Islands

BILL GOSNEY KE7C of the Whidbey Island DX Club (Bill also runs the *73* Awards Program and coordinates our SSB championships) sent in the latest list of countries for the **Island DX Award**. To qualify for the certificate, you must confirm at least 50 of the islands on the list. There are endorsements for SSB, CW, RTTY, SSTV, OSCAR, and so on. The list is pretty long; if you would like a copy, drop Bill an SASE care of the Whidbey Island DX Club, 2665 North Busby Road, Oak Harbor WA 98277.

Cliff Hanger

CLIFF WELLS KA7TVC decided to put an AEA Isopole up on his building in Kirkland, Washington. He asked the building's owner, who said it would be OK. Cliff put up the vertical so that it extended a few feet above the roof. Then a neighbor told him that the antenna was in violation of a city ordinance that regulates outside transmitting antennas, and that it would have to come down. Cliff asked about the ordinance at city hall, and was served a citation for breaking a three-year-old Kirkland law that requires a public hearing and a $350 fee whenever a transmitting antenna is put up. The best part: The law regulates *transmitting* antennas—if the Isopole were to be used only for receiving, it would be perfectly legal. Cliff has appealed the citation, and hopes that the law will be modified in light of the FCC's recent ruling on PRB-1.

Santec Save

CLIFF RODGERS of Beaumont, California, extricated himself from a tricky situation recently with the help of his trusty Santec HT. While spending the night in a motel "known for its low rates and cold pools," Cliff and his wife were disturbed by a loud pounding on the door. The view through the peephole was not promising, and Cliff decided to telephone the motel's security desk; unfortunately, the low rates included no phones. Thinking quickly (the pounding was getting louder), Cliff reached for his trusty HT and, with the help of a few local hams, got a message through to the motel's security man. The story has a happy ending, and Cliff notes, "Now when I go to faraway places with strange-sounding names, I always check to be sure my trusty HT is charged and packed!"

Firefighters rushed to the Dayton Hamvention after a smoking extension cord forced evacuation of the Wampler Ballarena.

Hambassador

ADVANCED ELECTRONIC APPLICATIONS, INC., has announced a new award designed to encourage hams who promote amateur radio to those outside of the hobby. The **Ham Ambassador Award** will be presented to the amateur who, in the opinion of the judges, has contributed most to introducing the public to amateur radio. A $1,000 prize will be presented to the winner, who will also receive round-trip airfare, meals, and hotel accommodations to the ARRL National Convention in San Diego on September 6, 1986. Any ham may nominate any other ham for the honor; the nomination must be made on a special AEA Amateur Ambassador Award nomination form, available by sending an SASE to AEA, PO Box C-2160, Lynnwood WA 98036. Nominations close August 15, 1986.

Top Ham

ROY NEAL K6DUE has been named **Ham of the Year** by the Dayton Amateur Radio Association (DARA). The award, presented at the Saturday night Hamvention Banquet, cited Roy for his outstanding contributions to the hobby, including his many promotional films ("Moving Up to Amateur Radio," "The World of Amateur Radio," and videos featuring the ham-in-space program) and his active role in convincing NASA that sending a ham transceiver into orbit with the space shuttle was "OK." Poor Roy had to give two speeches that night, as he was also the keynote speaker at the banquet. Saturday evening saw the presentation of two other honors: the **Special Achievement Award** to **Fr. Michael Mullen WA2GQW**, and the **Technical Achievement Award** to **Doug DeMaw W1FB**. Fr. Mullen is president of the International Mission Radio Association, an organization that equips hams involved in missionary work with amateur radio equipment. Doug DeMaw is world-famous for his easy-to-understand technical articles in *QST*, and served as the magazine's Senior Technical Editor until his retirement in 1983.

SARC Certificate

A SPECIAL AWARD IS AVAILABLE from the **Scarborough (Canada) Amateur Radio Club** to commemorate its 40th anniversary. To qualify, you must accumulate points by contacting VE hams: 20 points from VE3 and 20 points from other parts of Canada. For Canadians, every QSO counts one point. Contacts with stations using a special-event prefix or with members of SARC are worth five points. Ten points are awarded for a QSO with SARC club station VE3WE. For U.S. and DX operators, all of the points and bonuses are doubled. To claim your award, send a copy of your log, signed by two other amateurs, and one dollar or three IRCs to SARC, Box 174, Station D, Scarborough, Ontario, Canada M1R 5B5.

Bud Hill K1PD, Elmer to over 800 code students, receives a plaque of appreciation from Chelmsford ARC President Jim Fisk.

Extra Pool

THE NEW POOL of questions for the Extra-class examination has been released by the FCC. The pool of 456 questions must be used by volunteer examiners starting October 1, 1986, although VECs can start using them at any time. New questions have been added which deal with the volunteer examination program, including reimbursement, preparation of tests, and VE accreditation. Other questions have been modified slightly for clarification.

Packet Mania

NEXT MONTH is special! If you are interested in packet radio, don't miss the August issue of *73*...an entire issue devoted to packet! You'll find out how to set up your own station, discover the nuts and bolts of networking, and explore the esoteric side of the medium with the top names in the field. You won't want to miss this one—better check your expiration date!

SWL Pubs

TWO NEW PUBLICATIONS of interest to shortwave listeners are available from West Germany. The first, Dr. Jurgen Trochimczyk's Radio Beacon Handbook, lists more than 8.500 long- and medium-wave beacons from around the world. Stations are organized by callsign. The second book, Bern Friedwald's International Listening Guide, presents shortwave broadcasts in English, arranged by transmission time, and details their target areas and frequencies. Also included is a list of broadcasters' addresses. For information about the *Beacon Handbook*, contact Wilhelm Herbst Verlag, Postfach 45-05-06, D-5000 Koln 41, West Germany; if you're interested in the *International Listening Guide*, get in touch with DX Listeners' Service, Merianstr. 2, D-3588 Homberg, West Germany.

Code King

BUD HILL K1PD was honored recently by the Chelmsford (Mass.) Amateur Radio Club for 20 years of teaching Morse code. Bud has taught nearly 800 people the code, including 100 participants in the club's Police Amateur Radio Team (PART), an organization which meshes ham radio with law enforcement. When Bud first tried to learn Morse, his studies were impeded: "I couldn't practice code when my daughter's dog was in the house—he barked all the time." When asked how he solved the problem, Bud smiled and said, "They don't live here anymore."

New News

WHAT'S NEW THIS MONTH in *73*? A new feature, **Ham Awards, by Bill Smith N6MQS**, appears on page 107. Bill has been busy designing worksheets for the major on-the-air awards; every month we'll print a worksheet and a set of rules back-to-back so that you can cut the page out of the magazine and put it into a folder. On page 80 you'll find an order form for the all-new 73 **QSL Cards!** We've had so many requests for our high-quality, low-price QSLs that we've brought them back.

important!

AS REPORTED LAST MONTH in QRX, the FCC has proposed enhancement of the Novice-class license to include data and voice operation on three bands. The NPRM, PR Docket 86-161, calls for data privileges from 28.1 to 28.3 MHz, SSB from 28.3 to 28.5 MHz, all amateur privileges from 220 to 225 MHz, and simplex and repeater privileges from 1246 to 1260 MHz. There are power restrictions on each band: 200 Watts PEP on 10 meters, 25 Watts on 1-1/4 meters, and 5 Watts on 23 centimeters. The new rule would allow higher-class stations to run their legal limit in these Novice subbands. Novices would be allowed to operate through a repeater, but would not be allowed to be the trustee of one. Initial comments are due at the FCC by July 16th, and reply comments must be received in Washington by August 20th. To file comments, send an original and five copies (11 copies if you want each Commissioner to have one) to the FCC, 1919 M Street NW, Washington DC 20554. Include the docket number in the head of your comments (see page 89 for an example page). The Commission is especially interested in hearing what you think about reducing the term of the Novice license to encourage upgrading, and whether the General-class exam should be broken into two parts, one covering VHF and one covering HF, to help Novices upgrade to Technician.

QRV

THIS EDITION of QRX comes to you with the aid of *The W5YI Report*, *Westlink*, *Sweden Calling DXers*, *Splatter*, and Claire Azzalina. Send your photos and stories to *73* Magazine, WGE Center, Peterborough NH 03458.

NEVER SAY DIE

from page 4

and are ready to face lung cancer, heart attacks, and emphysema, well you'd better get busy getting more hams so we'll have someone to replace you—and soon. I can see the 2020 Hamvention with one ham creeping slowly into a hotel room in the Dayton Biltmore, moving his walker up to the card table exhibit of Japanese gear being sold by the sole remaining ham dealer . . . and asking for a discount.

A ham friend of mine has some houses he rents out to students at a nearby college. He keeps an eye on 'em and has been apalled to see that a high percentage of them are alcoholics. Many of them put away one or two six packs of beer a night. There's nothing like peer pressure to overcome common sense. I don't know how I managed to avoid getting messed up when I was in college. My fraternity brothers made a big deal out of drinking beer. Oh, I tried it, but it tasted awful, so I never learned to like it. I tried smoking, too—didn't like that either. I guess peer pressure didn't work well with me. I was never much of a follower—preferring, from an early age, to be a leader.

Look here, I know how difficult it is to diet. I'm a known fooder. I've been dieting since I got fat when I was about seven years old. I did thin down a bit while I was in the Navy—had to in order to look good in my tailor-made uniforms. In 1972 I got tired of being fat and went on a long, slow diet, taking off 85 pounds. And, unlike most dieters, I've managed to keep most of it off ever since.

I know all about fasting and dieting. My body is ready to fight back at the slightest sign of a food cutback. If I skip lunch, by two in the afternoon my body is in a panic—Oh God, he's fasting! It quickly gives me a big headache, makes me sweat, get dizzy, and feel as if I haven't eaten for a week.

Dieting isn't difficult, once I make up my mind to it. My body doesn't fight dieting like it fights fasting. I can lose a third of a pound day after day for months with no serious physical effects. Of course it does take a lot of resolve to pass up ice cream, desserts, and such nonsense.

A serious dieter has an accurate doctor's scale and weighs in meticulously every morning, ticking off the third-pound losses. A serious dieter wants that scale to go down so badly he brushes his teeth before weighing in to get rid of that heavy plaque, shaves to cut off that heavy stubble—and maybe spits a couple times for good measure. It's a good idea to check for ear wax, too.

Next year at Dayton I want to see a bunch of younger-looking old-timers, without those gross, disgusting beer bellies and hacking coughs, going by my *73* booth. We used to believe that youngsters were the future of amateur radio; now we know the odds are good that the future is us old-timers.

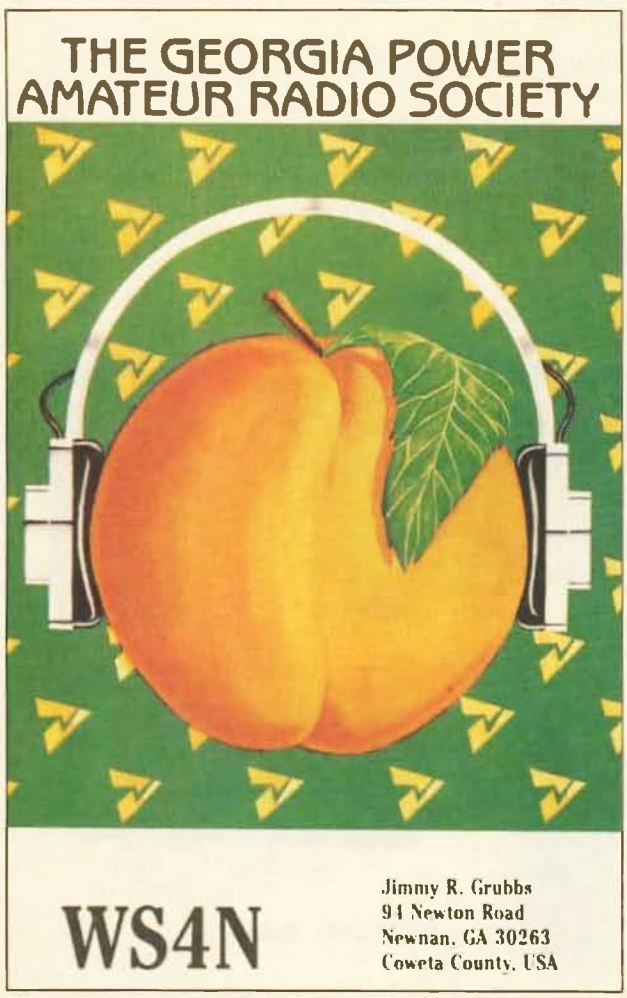
Look here, if anyone as weak-willed as I can diet and take off 85 pounds at one whack . . . and keep it off for 14 years . . . there's no good reason why you can't do it too. The next thing you know you'll be trimming down and joining me out there putting in a couple miles of brisk walking every morning. No, I'm not pushing for you to become a fitness fanatic—I just want you to be around to renew your subscription to *73* for a few more years and say hello to me at Dayton, Miami, Orlando, Dallas, Atlanta and so on.

A recent large-scale study on alcohol showed that even light drinkers substantially worsen their odds for living long lives. As I recall the radio CBS report, one drink a day cuts your chances of living to 72 in half. A couple drinks a day cuts it to one third. Now, how about a nice cold 807?

Thank heavens the studies show that sex contributes to longer life! It's a darned good substitute for liquor and cigarettes . . . unless your wife catches you.

Ham Industry Meeting

About a hundred ham industry people gathered at Dayton the evening before the Hamvention. Maybe 40 firms were represented—a pretty poor showing. The main concern for those concerned enough to come to the meeting was the increasing drop in new hams—down 8.5% over the previous year, with no turnaround in sight.



A year ago at Miami some industry people met and came up with an idea for a ham comic book as a way to interest youngsters in the hobby. That was while I was divorced from *73*, so I missed the meeting. This project is moving along slowly.

I explained the approach I feel is needed if we're going to get amateur radio really growing again. This means getting youngsters coming in again. In order to do that we need to rebuild the school radio club infrastructure which brought us hams until the clubs folded around twenty years ago—victims of the Incentive Licensing disaster.

I explained that we need to get what we have left in ham clubs to sponsor school radio clubs in their areas—Elmering them. No, it won't be easy. Schools will fight any changes, as they always have. They'll put up all sorts of obstacles to anything which means more work for them, even slightly more work. But if we work together, sharing our successes, we can do it.

Without a rebuilt radio club infrastructure, I don't believe comic books or TV shows about amateur radio will get us much. Look at how successful peer pressure is in getting kids to go for cigarettes, beer, pot, and coke! It used to be as effective selling amateur radio—with benefits to everyone. Most kids got started on lifetime high-tech careers—our country had the engineers, technicians, and scientists which put us number one in the world in technology.

It's up to us whether we'll be bringing over more and more Japanese technicians to repair our radios. Remember, we're

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, WGE Center, 70 Rte. 202 N., Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

heading into a communications age beyond anything you've imagined. We're going to see communications expand by a factor of a thousand to a million over the next few years. This is going to require millions of engineers and technicians—are they going to be American or Japanese? The answer is up to you and your ham club.

The industry people listened politely and most agreed with my proposal. But of course the old code-free license matter came up. Maybe, if we can get a code-free license, we can get youngsters into amateur radio. Maybe, but without the school radio clubs, I doubt it.

Only one person held out for maintaining the Morse-code test, with the others all in favor of some sort of no-code test. The holdout's credibility was somewhat weakened when it was noted that his firm's main business is selling code courses. It seemed like a triumph of self-interest over reason.

The next obvious question was, well, if just about every industry person wants a no-code license, how can we get one? The FCC's Johnny Johnston was there, so they asked him what might do it. Johnny made it clear—the FCC went to a lot of time and expense to try to get a no-code license. The ARRL killed it, put it in its coffin, and drove a stake through its heart. The only way you're going to get the Commission to reconsider no-code is by getting the ARRL to pull the stake back out of its heart.

Hmmm. How can we do that, they asked? Lew McCoy, who spent much of his life working at ARRL HQ before he retired a few years ago, got up and explained the facts of life. If you want the ARRL to favor no-code, it's very simple. You have three other ham magazines for your advertising—*CQ*, *73*, and *HR*. If you move your ads from *QST* to the other magazines you'll have the ARRL Board down picketing the FCC for a no-code license.

Everyone agreed Lew was right. It was too self-serving for anyone from the three magazines to do more than join the cheers. No one from the ARRL bothered to come to the ham industry meeting, so there was no comment from them.

I will frankly be surprised if any advertisers have the guts to try and put pressure on the ARRL. I watched every major manufacturer go bankrupt or change to some other business twenty years ago, advertising first in *QST* right to the bitter end. You can look back in your old copies of *QST* at the ads by Hallicrafters, Hammarlund, Johnson, Barker & Williamson, Webster, Sideband Engineers, Gonset, Central Electronics, Harvey Wells, Multi-Elmac, World Radio, Lakeshore Industries, Eldico, Sonar, RME, Millen, National Radio, Thordarson, United Transformer, and so on.

It'll be interesting to see what happens. My bet is that nothing will. Safe bet, at least for quite a while. Until we have school radio clubs in place to help youngsters get licensed, it seems irrelevant to me. Once we have 'em, you'll see me pushing to replace the outmoded code exam with a tougher technical exam—getting away from forcing kids to learn an unneeded skill in this packet world and into really getting started toward technical understanding, which will stand them in good stead the rest of their lives.

It would be nice if the ham industry people became more involved with the health of their industry. They certainly have everything to gain from a fast-growing hobby as compared to the dying one we have now.

Will I be seeing you at Dayton next year? Will I be seeing a new, thinner you? A you which doesn't stink of cigarette smoke? It's the big show of the year, so see what you can do.

A NICE THICK MAGAZINE

One thing that gets mentioned frequently is how much you prefer a nice thick magazine to a little bitty skinny one. Me too, even though it's a lot more work. With some cooperation from you, we'll have *73* so thick you won't be finished with it by the time the next issue arrives—you know, like it was a few years ago.

The formula for a thick magazine is simple—the more ads we have, the more pages of articles we can run. While I don't have to make any money with *73*, I also am not dumb enough to plan to lose a lot of money with it. How do we get more advertising? That's simple too—one way is by getting more readers so ads in *73* will sell more products. Another is to let advertisers know when their ad in *73* got the sale for them.

I'll appreciate any help you can give on getting subscribers. Maybe you can do something with your club—I've got some special bonuses for clubs. Perhaps your club is going to have a hamfest or auction and could run a *73* table. Or maybe you have an idea I haven't thought of yet. You know, less than half the hams read *any* ham magazine. Maybe you can find out why they don't—or even better, how I can get them to break this disgusting habit. Check around and let me know. . .okay?

If advertisers think one of the other ham magazines is going to sell more gear for them, they'll spend their ad dollars there and I'll have fewer pages for you. If you're into heavy-duty construction projects, patronize *HR* advertisers. If you're into contests, hit on the *CQ* advertisers. If you want a bigger, fatter *73*—and no, I won't write more pages of editorials than I'm doing now, so don't gripe about that—with more simple construction projects, more reports on OSCAR, packet, and other fun activities—run your fingers, do not walk them, to the Reader Service card. Next, pick out the advertisements which almost have you ready to write a check or make an 800 call to order—mark the card and get it to me.

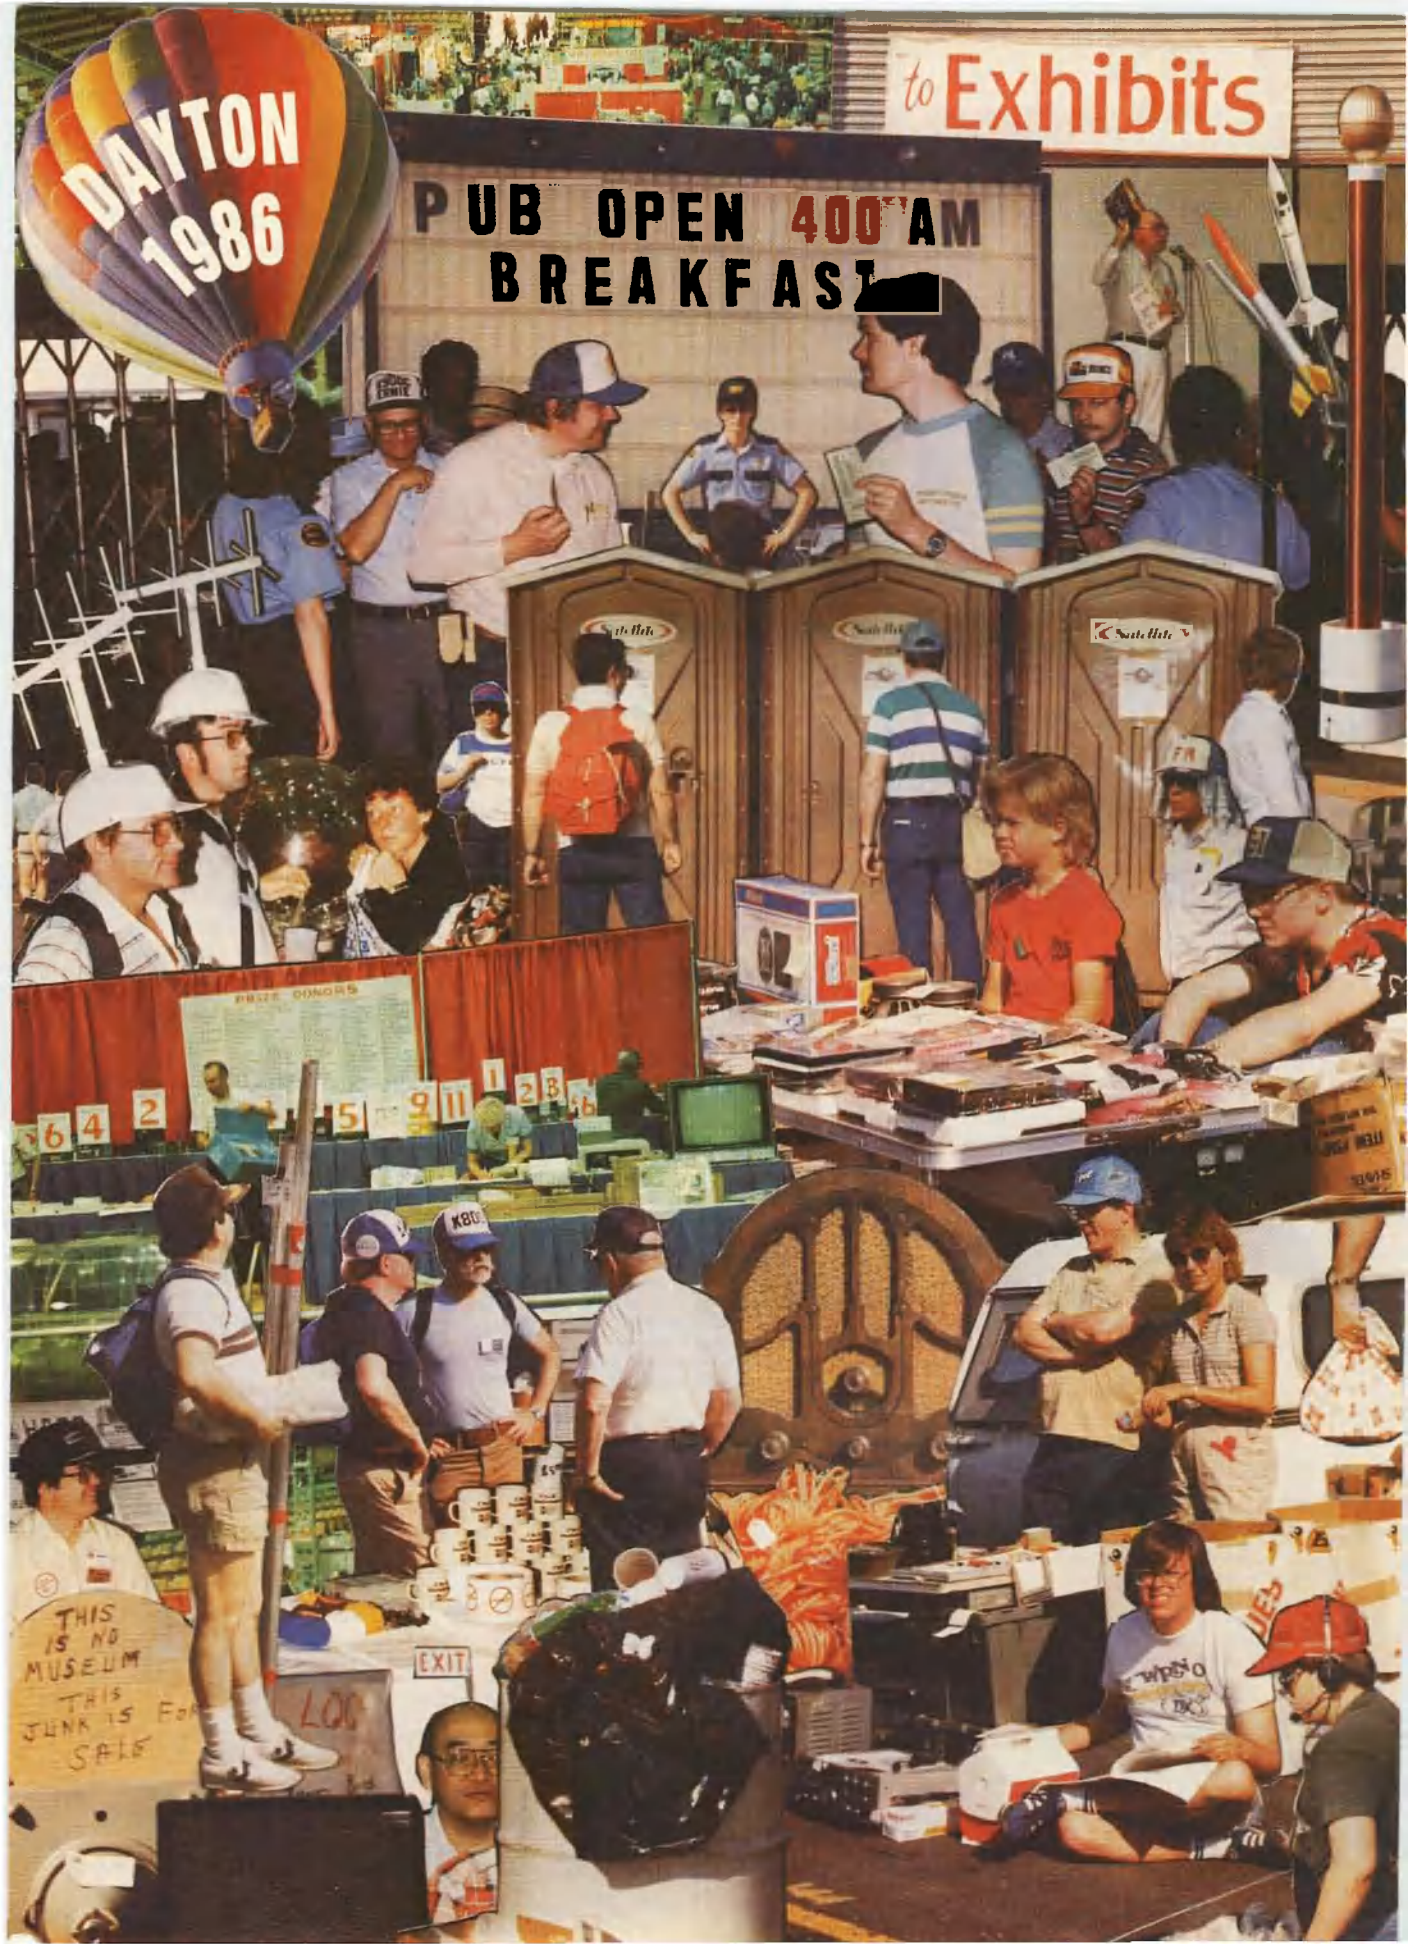
Buying new gear is one of the most exciting parts of hamming. It's exciting to open the box, get the gear set up, and make that first contact! Two demerits if you have to use the instruction book. Tsk. I'd as soon consult an instruction book as ask directions when I'm lost. No way!

Unless you're really into reincarnation, you've got to plan to only live once. You aren't going to waste a whole lifetime sitting there braying on 75m are you? Or waiting forever for someone to discover your repeater by accident? Or do you have two repeaters? With 9,759 active two-meter ops and 10,627 repeaters, a few of you have more than one repeater. Amateur radio is a whole bunch of fascinating hobbies, so why get hung up on just one? Have you tried slow scan? 2m Aurora? 80m DXing? 10 GHz? RTTY? I have and I loved every minute of it!

One of the great pleasures of publishing *73* is my responsibility to test out new ham gear. Boy, is that a tough job! Heh, heh. I just love prying the damned staples out of the boxes, then trying to shake the unit and its foam insert out of the box. There are all those plastic bags with cellophane tape which tears the bags when you try to open 'em. Each cable, connector, fuse, and other accessory is always bagged and taped. But when I get it all set up and turn it on—ahhh, nirvana.

It doesn't matter if it's a two-meter mobile rig, a 220 HT, a new slow-scan monitor, or a new keyer—it's exciting and I can hardly wait to see how it works and tell anyone all about it who blunders onto my frequency.

If you see an ad in another magazine which you just can't pass up, the least you can do is drive the manufacturer or dealer crazy by telling 'em you saw their ad in *73*. Chuckle.



You know, if we can get school radio clubs back in business, I think we'll start seeing new young hams by the zillions—and we both know they're going to be reading *73*, where the action is. Can *73* ever get to be the size of *Byte* and *80-Micro*? Sure it can! And hamming will be one of the best known hobbies in the country—a hobby you can really be proud of. You know, both *Byte* and *80-Micro* got up to 600 pages a month—how'd you like to face that? They used to give postmen hernias.

I had a postcard the other day from a very confused reader who somehow had managed to convince himself that I took on *73* in order to make money. Great fantasy. As far as I recall, I never made much, if any, money with *73*. How do you run a business losing money every year? Mostly by being smart enough not to lose enough so you go out of business. It's called the Ponzi Scheme after a chap in the 20s who made millions with the idea.

When CW took over *73* they looked at it and decided running a magazine for fun was crazy, so they set it up to make money and damned near killed it. No one makes money with ham magazines except the ARRL. Computer magazines make millions. Audio magazines make millions. Ham magazines, at best, break even. That's my experience. Of course if we manage to develop 1% of the population into hams—about 2.5 million—and the *73* readership goes up to maybe 500,000—then I might not be able to prevent myself from making money. No, I'm selling myself short. . .I'd manage. Let's get those 2.5 million hams and I'll prove it.

In the meanwhile please get your Reader Service card to me—and none of that marking every number, either. If I think you're fudging it just to try and cozy up to

COLD CLUB

My wife, bless her heart, let me talk her into getting involved in my hobby. Since I don't have the patience to teach a family member anything, I figured a radio club would be a good introduction.

We chose the club at her place of work. I won't name names, but it is a very large electronics firm here and they have one of the oldest clubs in the state. When the meeting started, they had the usual reading of the minutes and such. Then the subject came up that the club needed an item for its repeater. The fellas that wanted the club to buy it were asked to give the reasons. After a short discussion with a lot of "humms" and "ahs," they admitted that they guessed they didn't need the item after all, especially since they didn't intend on putting the device in anyway. They figured someone else could do that. No one had the time to work with it, so they didn't buy it.

Then it was time to nominate a new president. Everyone looked at each other, waiting for someone else to talk. Either no one cared, or they felt they might have to be president if they opened their mouth. They never did nominate anyone that night. How sad!

Another year and these guys will be gone. In the hour and a half not a word was said to us, as if we were not there or not welcome. Not real inviting. They did, however, have a very nice talk about propagation. I learned a lot from that, but my wife was pretty bored.

There is another club in town that we're going to try. It is much more active, I'm told. I sure hope so! One club isn't a good sample, but from what I've been reading, this one was a good example. Truly sad.

HAM AM

I have to admit that I was angered by the statement in Perry Donham's April QRX column that "the whine of heterodynes" will be returning to our voice bands. My reaction was not because I favor the abolition of full-carrier DSB AM, but because the statement went on to become a gross distortion of the arguments raised by Don Chester K4KYV and other AMers who are protesting the 50% power reduction to be forced on them when FCC Docket 82-624 takes full effect in 1990. The segment seemed phrased to do little more than to try to inflame our SSB brethren and to try to dismiss AMers as a few reactionary old stick-in-the-muds.

Far from being dead, AM is returning with a vengeance, with scores of new stations coming on each year in different areas of the country. It's ironic that AM, the pioneer voice mode, is once again a "growth mode." This seems to point out to me that something fundamental is missing from today's amateur radio. The AM resurgence had been confined to the Northeast, but is now picking up in the South and the West and in other regions. Credit for this in many ways goes to the Society for the Promotion of Amplitude Modulation (SPAM) and to the *AM Press/Exchange* magazine.

There are many reasons for this return to AM activity. Number one is because the design of a DSB AM rig is very basic. It's the simplest voice rig to design and build. You can throw one together in a weekend if you cheat a little bit and use a stereo or PA amp for a modulator. Reason number two is that the equipment and parts are available for a song at hamfests. They are usually hidden underneath the tables and scorned by most hams as junk. Reason number three is that it is just plain old fun. The element of fun is what will attract newcomers to our hobby and sustain it into the future.

Right now I can see all the hi-tech computer and packet types chuckling among themselves. So what if most AM technology is not state-of-the-art; it can be and in commercial AM transmitters it is! AM is easy to understand, it is easy to fix, it teaches people something about radio theory, and it is fun. The emphasis of amateur radio does not always have to be on hi-tech. The use of AM should be seen as a logical step in educating oneself about electronics and achieving mastery over analog electronics. From there you can move onto digital electronics. I feel it is important to know from whence you came.

The continued use of AM is in no way a threat to our bands, or to anyone else trying to pursue his end of the hobby, be it SSB, RTTY, or whatever. This is because we do live in an age of hi-tech, and AM will remain a minority mode in use by only a few hundred or a few thousand newcomers or experimenters.

Use of high-power class-C plate-modulated amplifiers on AM has taught me more about radio than anything I could have picked up using a TS-820. Contrary to Perry's claim that there are very few class-C plate-modulated rf amplifiers in use, there are thousands in use the world over in communications and broadcasting. I have been able to take the knowledge I gained in amateur radio and apply it to my job. Those thousands of rigs will still be out there into the next century, and somebody is going to have to fix them.

I recently saw a small crowd of hams at a hamfest gathered around a table where there was a small object that no one could identify or explain. It was a vacuum capacitor! One fellow asked me how many Watts he could expect to get out of "that tube." I'll bet he got his radio education putting together Heathkits and now sends his ICOM back to the factory when it breaks. All I would like to see is an end to the blatant discrimination against AM, AM users, and AM groups by the FCC, the ARRL, the mass-circulation ham magazines, and by the SSB jammers. I'm not talking about bringing back spark; I just would like to see AM come out of the closet and have hams recognize that AM is still a part of modern communications.

I am continually fascinated by the progression of technology, the rise of solid-state, LSI, computers, packet, etc. However, I feel that AM still has a place in amateur radio for the beginner, the experimenter, or the hi-fi enthusiast. AM can be state-of-the-art, too. How about an all-solid-state hi-fi AM rig? There is now a 50-kW commercial AM rig available. I personally want to experiment with pulse-duration modulation. What about AM stereo or multichannel techniques, or synchronous detection for hi-fi reception? The potential for experimentation on AM has been too long ignored by the ARRL, the ham magazines, and the general ham population that has been brainwashed into thinking that AM is dead. The potential is still there; it just cries out for use.

It is because of this continuing value of AM to the hobby that I protest the PEP power determination method that replaced the old 1-kW-dc-input rule. What is so difficult about multiplying two final amplifier parameters that caused the FCC to decide that we will all have to buy PEP power meters by 1990? Have amateurs forgotten how to do multiplication? Also, PEP has always dealt with phone transmissions. Will someone please tell me how you read the peak ENVELOPE power of a CW or FM transmission where there is no modulation envelope! The thrust of Docket 82-624 seems to be that amateur radio will eventually be turned into a CB-type service where the operators have little knowledge of the inner workings of their equipment.

No other group seems to have been singled out for so much legislative abuse. What other group will be forced to cut its power by 50%? Several times the FCC has come close to "deregulating" my favorite part of the hobby out of existence with dockets such as the power reduction or the ill-fated Docket 20777 of the mid-1970s that would have banned AM below 30 MHz by regulating bandwidth instead of restricting modes. It is this repeated legislative abuse that comes every few years that has the low-band AMers up in arms and speaking out. I for one am sick of having to fight to justify AM's existence every two or three years when some bureaucrat at the FCC or a "professional ham" at the ARRL cranks out yet another make-work deregulatory proposal to limit bandwidth to 3 kHz, cut AM power by 50%, ban AM below 30 MHz, or otherwise shut down full-carrier AM phone on the low bands so that a few more SSB appliance operators can be squeezed in to chase DX or participate in some inane contest.

AMers, myself included, are speaking out at last because we have realized that we can expect no help from the ARRL or the major ham magazines. I have not seen any mention in *QST* or *73* about the appeal of the FCC Docket 82-624 power reduction that has been filed by Glen Baxter K1MAN with the U.S. Supreme Court. It would be the first time in years that the Supreme Court has heard an FCC case involving amateur radio. AMers will continue to

speak out because rumors have been circulating about various 75-meter SSB groups trying to petition the FCC to eliminate AM from the band or to restrict it to certain frequencies. Another threat to AM is the recent ARRL board discussion about sending a proposal to the FCC to establish a 160-meter band plan that would make the frequencies below 1840 kHz CW only.

AM is a mode that is relevant to today's world, and will continue to be for some time to come. It is well suited to attracting new or younger hams with limited funds or little electronic expertise into amateur radio. I say let the AMers pursue their interests unmolested and let the packeteers, SSBers, RTTYers, and CW people pursue theirs. There is room for all with cooperation. It is the diversity of operating modes and frequencies and our ability to experiment with them that distinguishes us from CB. If you destroy that, you have destroyed the hobby.

James D. Seaman WA2AJM
Guilderland Center NY

OK, you've convinced me that AM has a place in amateur radio. I will still grind my teeth every time I hear a heterodyne, though.—KW1O.

DECENT EXPOSURE

My first exposure to radio and electronics came in the late 50s when my father gave me an AM crystal set which I attached to the bedpost of my bunk bed. I spent many hours "DXing" the Midwest listening to the farm reports.

Later I saw a Hallicrafters shortwave receiver at the local appliance store. It had an AM band and three shortwave bands with little dots marking the places I should listen for foreign cities like London, Moscow, and Amsterdam. It wasn't even hooked up for demonstration, but I convinced my dad to buy it anyway. I soon found out that the little dots marked on the receiver had no correlation to the countries listed, but I did find a surprising number of stations grouped into various areas of the spectrum from 1.6 to 30 "megacycles."

I found other areas of the bands where strange men talked about Viking Rangers, Hammarlund receivers, and dipole antennas. I also heard them talk about something called "single slop-bucket," how it would ruin the bands, and how they would never change from amplitude modulation. I heard a few men using what I supposed to be "single slop-buckets" but I had trouble tuning them with my bfo. They tended to sound like Donald Duck.

This was my first exposure to amateur radio.

Later on, during my high-school days, I learned that some of the older boys had formed a "ham radio club" and were interested in teaching other boys and girls about this strange hobby. I attended several of the meetings of the club after school and found that they were teaching something called "Morse code." I had heard this strange code on my shortwave radio, but really had no interest in learning it. I wanted to talk to the men about dipole antennas and "single slop-buckets."

The boys who taught Morse told me if I wanted to talk to the men I had heard, I would have to learn the code first. I thought this was strange, but I gave it a try. Well, unfortunately, I wasn't very good at learning the code, and the boys teaching it seemed to want to pace the class for the better students. I tried for about four weeks, but finally got frustrated and gave up.

I still wanted to know about things like amplitude modulation, dipole antennas, and "single slop-bucket." I continued to listen to my shortwave radio. Soon, most of the men on the amateur bands started using "single slop-bucket," and I stopped listening to them because they all sounded like Donald Duck, and I couldn't tune them in well enough to enjoy it. Besides, I could always listen to the BBC, Switzerland, and HCJB in Quito, Ecuador.

Well, that was 20 years ago, and since that time I have gone on to a career in electronics, first as a technician, then as a supervisor, and now as a manager of quality assurance for a company in the telecommnications industry. But you know what, until I met Gordon West WB6NOA and Loraine McCarthy N6CIO, I still hadn't been able to master the Morse code.

That little detail held me back for 20 years!

But not any more. Thanks to Gordon and Loraine, the "Queen of Code," I am now N6NKN, an FCC licensed Technician-class operator (my license was in the mail when I got home yesterday).

I cannot say enough about these fine folks. Their patience, understanding, and ability to make learning code and theory fun has contributed to the hobby immeasurably.

Most of their students continue to pursue the hobby for their Technician- and General-class licenses. I'm currently trying to push back the wall I seem to have hit at 10 wpm, but soon I'm sure I'll be able to get on 40-meter phone, or CW, and talk about dipole antennas and something called packet radio.

Some of the men I hear say packet radio will ruin the bands, and that they will never give up RTTY, AMTOR, and single sideband. I guess I really haven't missed that much in 20 years, have I?

Richard J. Zolla N6NKN
Irvine CA

SOVIET SWAP

I have been very lucky! My little boy became a General at the age of 9 and my daughter became an Extra when she just turned 12. I taught them both, and then they taught each other. My son is getting ready to beat his sister's record.

Folks have asked me to write a book to help children become hams. I suspect it will really be for adults! The secret to get the kids to learn and pass amateur exams is to teach it with a story. Kids love stories to learn from and so do adults, especially if the characters remind them of themselves. Maybe that is what is needed in *73*—a monthly section devoted to kids with a good story to help them walk through magic radio land.

I am establishing a project, "Amateur Radio Children For Peace," between the USA and USSR. I am in the process of contacting some amateurs in the Soviet Union. The purpose would be to facilitate cultural relations and awareness between licensed amateur-radio operators in the early adolescent ages between both countries by scheduled on-the-air contacts. Simultaneously, on a yearly basis there would be an exchange of participants for two weeks living among the amateur-radio community in each country. The aim is to appeal to the children of both countries, with hope that friendships will be established and fostered. Since amateur radio knows no boundaries, neither should there be limitations on the communication of love and peace.

I think this may be a rather interesting project since amateur-radio operators of both our countries talk to each other every day anyway. Encouragement of such participation, especially with the children, has its obvious advantages.

I would appreciate any recommendations and support you may have to offer. I am in the process of contacting the Moscow Radio Club and the American Radio Relay League for assistance. In the meantime, I am trying the experience with my two children. You should have seen the expressions on my kids talking to RW3DP this past weekend!

Richard Niemtzow N5EV, M.D., Ph.D.
Andrews AFB MD

GOOD START

Your April editorial stirred me to sit down and comment on the TNS/Stoner proposal and give some ideas regarding the lack of growth in ham radio.

I'm not sure that I agree with all the details of the Stoner proposal, but I do agree that a code-free class of license is a must (contrary to the ARRL) to get our hobby growing by leaps and bounds. A digital class of license is a good start. I would also suggest that additional privileges could be granted according to the ability to build (even from a kit) equipment to be used on the air.

As a self-employed person engaged in parts sales and service of CB/ham/hobby electronics, I find many old-time hams are simply knob twirlers who have to pay someone to wire mikes and solder coax connectors while they sit back and complain that no one should be a ham until he learns Morse code! Vast numbers more buy parts but don't know what to do with them, go home and blow up the parts by wrong connections, and then get on the air and tell everyone that I sell bad parts—and not to patronize my business. That, after I spent time drawing out on scratch paper simple circuits for them with no charge for my time!

Ken Losey KA8RUA
Kalamazoo MI

NEW PRODUCTS

ROBOTICS WORKSHOPS

A new series of robotics workshops is now available from Multibotics, Inc. The workshops are built around the B-100 interface module, which allows a host computer to perform as a motor controller, a voltmeter, a storage oscilloscope, an infrared controller, and an audio digitizer. Projects include demonstrations in motors and gears, generators, feedback, digital electronics, moving vehicles, and electronic speech.

The workshops range from $59.95 to $199.95, and are available for the Apple IIe, Atari, Commodore 64 and 128, Amiga, and IBM compatibles. For detailed information, contact *Multibotics, Inc., 2561 South 1560 West #A, Woods Cross UT 84087.* Reader Service number 152.

ORION ANTENNA ROTATORS

Orion Hi-Tech has announced the introduction of the RC5A-series of heavy-duty antenna rotators. The rotators are designed for large arrays, and employ high-tension-steel gear mechanisms. The rotors include a mast guide that makes centering easy.

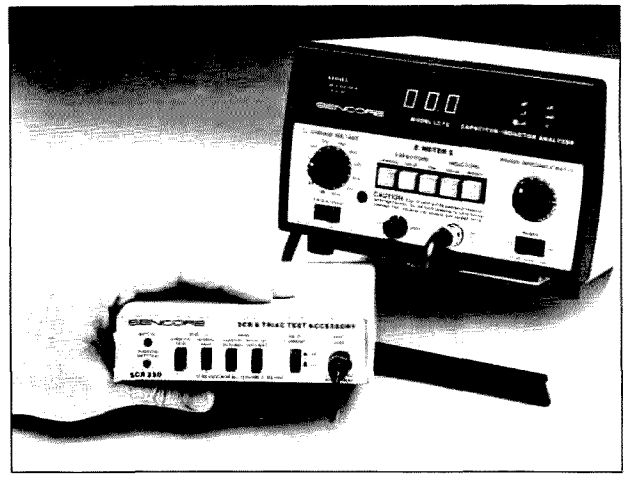
For complete information, contact *Orion Hi-Tech, PO Box 8771, Calabasas CA 91302.* Reader Service number 167.

LYNX CABLE-TIE TOOL

A compact, lightweight tool designed to speed up on-site installation of cable ties has been added to the Lynx product line. The QC-100 tensions, ties, and trims the tail off of cable ties with a simple twist of the user's wrist.

For more information, contact *Lynx, Inc., PO Box 67, Leominster MA 01453; (800)-222-LYNX.* Reader Service number 156.

A.P.E. PCB REPAIR KIT



The model SRS-050 Track Repair Kit from Automated Production Equipment contains all of the material needed to repair printed circuit boards. Repairs are made with a variety of copper-foil etchings that match the existing traces. Plated-through holes are repaired by swaging an eyelet into the board.

The kit is available in four models: standard, service technician's, basic, and deluxe. The kits differ in the tools supplied, and range in price from $18 to $129. For more information, contact *Automated Production Equipment Corp., 42 Peconic Ave., Medford NY 11763; (516)-654-1197.* Reader Service number 159.

SENCORE Z-METER

Sencore has introduced an improved version of its popular Z-Meter, the model LC-75 Z-Meter 2. The new instrument checks capacitor value, leakage, and dielectric absorption in half the time required by the earlier unit.

The Z-Meter 2 checks capacitors from 1 picofarad to 200,000 microfarads to 1% accuracy, with full autoranging. The distance to a break in a transmission line may be determined by dividing the transmission line's rated capacity per foot into the capacitance indicated by the Z-Meter 2. The meter also can check triacs and SCRs with the addition of the optional SCR-250 triac/SCR accessory.

The Sencore Z-Meter 2.

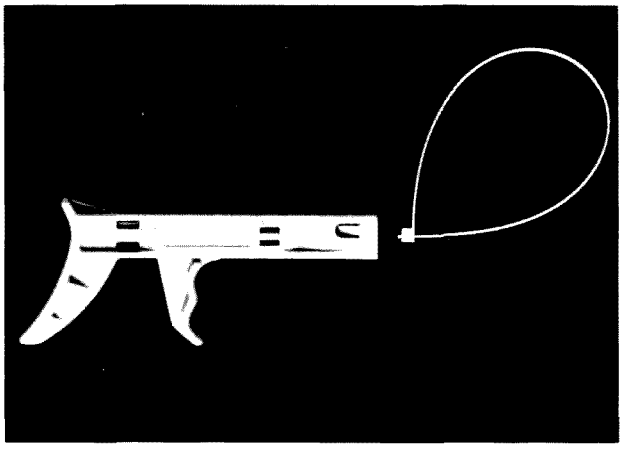
The LC-75 Z-Meter 2 is $995, and the optional SCR-250 is $148. For more information, contact *Sencore, Inc., Sioux Falls SD 57107; (605)-339-0100.* Reader Service number 154.

LARSEN 2M PORTABLE WHIP

Larsen Electronics has introduced the model KD14-2M-HW Kulduckie™ 2-meter portable whip. The antenna is cut for 144–148 MHz, and collapses from its extended length of 41 inches to an easy-to-carry 7-3/4 inches. The KD14-2M-HW employs a resonant half-wave design, with a rigid impedance transformer at its base. It connects to a standard BNC jack.

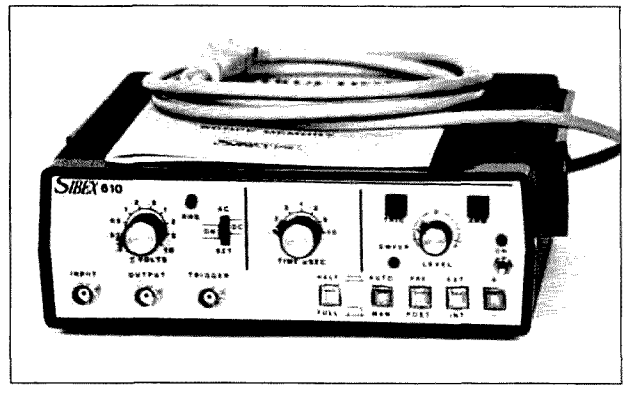
For more information, please contact *Larsen Electronics, PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 151.

ALUMA TOWERS



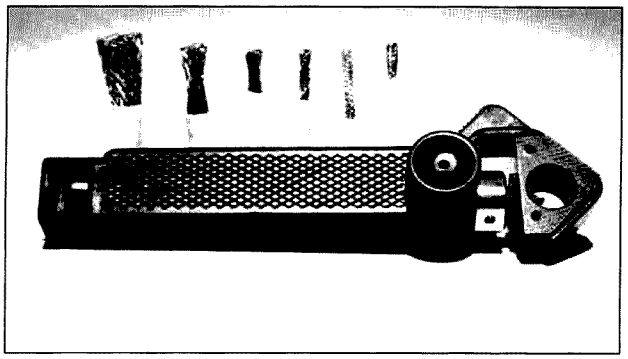
Aluma Tower offers trailer-mounted communication towers, ideal for mobile testing, site selection, and temporary installations. Available in up to 100-foot heights, the towers can be cranked up manually or with a 12-V winch. The trailers come complete with a 2"-ball hitch, spring suspension, and taillights.

For additional information about Aluma towers, contact the company at *1643 Old Dixie Highway, Vero Beach FL 32961; (305)-778-0606.* Reader Service number 158.

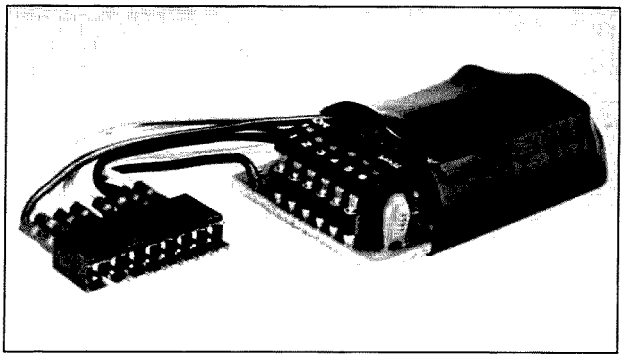


SIBEX SCOPE MEMORY

Sibex, Inc., has announced the model 610 oscilloscope memory. The model 610 has a 10-MHz maximum sampling rate and can store signals with a frequency of up to 1 MHz. Input sensitivity is 10 mV/division. The unit features pre- and post-triggering and a digital sweep function.



The model 610 memory unit is available for $985 from *Sibex, Inc., 3320 U.S. 19 North, Suite*



Cable-tie tool from Lynx.

The Sibex model 610 oscilloscope memory.

The CO-AX3 coaxial stripper by Davle Tech.

Selectone's ST-138W CTCSS encoder/decoder for Regency portable radios.

410, Clearwater FL 33519. Reader Service number 153.

BIRD BOOK

A new 60-page catalog of Thrulineoreg directional wattmeters, coax load resistors, calorimeters, and rf components is available from Bird Electronic Corporation. The catalog includes a comprehensive reference guide to rf measurement instrumentation and components from 2 milliwatts to 250 kilowatts in the range of 0.235–2,300 MHz, featuring triple-indexing by function, power level, and model number.

The publication is free—ask for GC-86 from *Bird Electronic Corporation, 30303 Aurora Road, Cleveland OH 44139; (216)-248-1200.* Reader Service number 160.

KENT MORSE KEY

R.A. Kent of Great Britain offers a solid brass Morse key in kit form. The machined hardwood base measures 8" x 3" x 1-1/2", and the solid brass arm is 6" long x 1/2" x 1/2". The key features ball race bearings and solid silver contacts.

For more information, please contact *R.A. Kent, 243 Carr Lane, Tarleton, Preston, Lancs PR4 6YB, Great Britain; (0774-73)-4998.* Reader Service number 161.

DAVLE TECH COAX STRIPPER

The CO-AX3 is a new coaxial-cable stripper designed for accurate removal of the outer sheath from twisted-pair coax and other irregularly shaped cables. A spring-loaded cutting head follows the contour of the cable, giving a precise cut to a specified depth. The cutting blade may be rotated 90 degrees to make a longitudinal cut, and a retractable ripping blade aids in splitting open cable insulation.

For more details, contact *Davie Tech, Inc., 2-05 Banta Place, Fair Lawn NJ 07410; (201)-796-1720.* Reader Service number 162.

NYE QRG DISPLAY

The Nye-Viking QRG Display is a VHF/UHF frequency counter with six big red digits which display your listening frequency. An automatic offset is built in for the 144-, 220-, and 440-MHz bands, with a remote switch for simplex or duplex operation.

The display is designed to be installed in the rear window of a car. The display remains dark until you transmit for at least four seconds, then the display will light up, showing the frequency you are listening on. The QRG Display can also be wired into the car's brake lights—six red eights appear when the brakes are hit.

For complete information about the QRG Display, write *Wm. M. Nye Company, 1614 130th Avenue NE, Bellevue WA 98005.* Reader Service number 163.

HAMTRONICS CATALOG

Hamtronics' latest catalog is ready for mailing. The 40-page, two-color catalog features many new products, including new GaAsFET preamps, a five-function DTMF decoder/controller, a T/R relay module, digital FSK modulators/demodulators for computer interfacing, and packet-radio VHF power amplifiers.

For a copy of the catalog, please send $1 ($2 for overseas mailing) to *Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535.* Reader Service number 164.

CTCSS ENCODER/DECODER

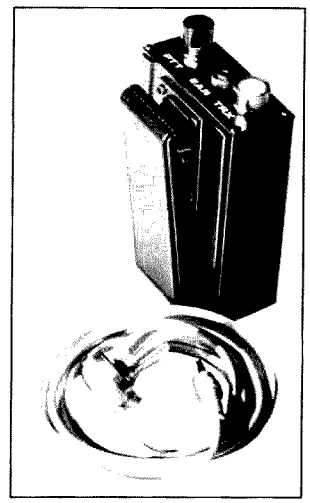
A new DIP-switch-programmable CTCSS encoder/decoder for Regency portable radios is now available from Selectone. The model ST-138W Digitone™ unit measures only 0.15" x 1.05" x 0.4" and comes wired with an 8-pin connector which mates with the tone-option harness in the Regency MCPH-, MCPU-, and NC-102-series portables.

The ST-138W draws less than 7 mA at 5.6 to 26 V dc and provides 38 CTCSS tones from 67.0–250.3 Hz. It includes a high-pass filter and crystal control for accuracy and stability.

You can receive more information about the ST-138W by contacting *Selectone Corp., 23278 Bernhardt Street, Hayward CA 94545; (415)-887-1950.* Reader Service number 157.

INTER-EAR COMM SYSTEM

Ace Communications, Inc., has augmented their line of in-the-ear listening devices to include a unit which also transmits. The IECS-200 replaces the speaker/microphone on an HT and allows hands-free communications in noisy environments. The IECS-200 will interface with any radio that has an external speaker and microphone jack.



For complete details, write or call *Ace Communications, Inc., 22511 Aspan Street, Lake Forest CA 92630-6321; (714)-581-4900.* Reader Service number 155.

COAXIAL DYNAMICS WATTMETER, FS METER

Coaxial Dynamics has introduced two new meters to their product line. The 83000-A peak-reading wattmeter features a measuring capability of from 0.1 to 5,000 Watts in the 2–1,000-MHz range with plug-in elements.

The model 7600 field-strength meter offers high sensitivity, broadband operation, detachable antennas, adjustable gain control, and a large meter. Its frequency range is from 1 to 1,000 MHz.

You can get additional information on these and other rf products

The IECS-200 inter-ear speaker/microphone by Ace Communications.

by contacting *Coaxial Dynamics, Inc., 15210 Industrial Parkway, Cleveland OH 44135; (216)-267-2233 or (800)-COAXIAL.* Reader Service number 165.

R-2000 REPEATER CONTROLLER

Resultant Engineering has introduced the R-2000 microprocessor-based repeater controller. The R-2000 features an easy-to-use touchtone™ command language, over 30 user operations, a voice synthesizer which responds to your commands with interactive messages, a real-time clock, on-board subaudible-tone and DTMF decoders, autopatch, a mailbox and a bulletin board, two RS-232C ports, a watchdog circuit, and CMOS construction with battery-backed RAM.

For complete details, contact *Resultant Engineering, 175 East Homestead, Suite 5, Sunnyvale CA 94087; (408)-732-9482.* Reader Service number 166.

Kenwood TH-31AT

by Peter H. Putman KT2B

Trio-Kenwood
Corporation
1111 West Walnut St.
Compton CA 90220
Price class: $235

Photo A. The TH-31AT: "slight" of hand?

Oops! Now where did that handie-talkie get off to? Nope, not in my pocket, not in the drawer, not under the bed.... Ahhh, there it is. It slipped under the crack in the door!

Not to be facetious, but this is truly the smallest radio I've ever used. It sort of resembles a microphone with an antenna attached! Yet, the Kenwood TH-31AT will yield hours of operating enjoyment on 220-MHz FM.

This was truly an impulse purchase. While at the LIMARC hamfest on Long Island in February, I felt some money burning a hole in my wallet, so it was a short time before said cash and I were soon parted. I wound up with the basic radio plus an extra battery pack as a bonus from the dealer. In addition, I purchased a third pack for backup. I also bought the AJ-3 antenna-conversion plug (more on this later) as well as the DC-21 dc power converter. A Larsen magnetic mount and 5/8-wave whip rounded out the deal.

What's In It?

As soon as I opened up the box, I was amazed by the small size of the radio without the slide-on battery pack. With the standard pack, the TH-31AT measures in at 4-3/4" tall by 2-3/8" wide by 1-1/4" deep. That's not a lot bigger than a cigarette pack. In fact, the rubber-duck antenna is taller than the transceiver! The PB-21 battery pack measures in at 2-3/4" tall by 1/2" thick, so you can see that there isn't a lot of room for the guts of the radio.

Kenwood rates the radio at 1 Watt output across 50 Ohms in the high-power position. Using a Bird 43 and a 5-Watt 100–250-MHz slug, I measured 750 mW with three differently charged batteries. The supplied pack is rated at 7.2 volts, so I experimented with an outboard dc converter that supplied 8.5 volts, but no change was apparent in output. Low power is rated at 100 mW and this appears to be the case, based on the Bird measurements.

Battery life is estimated by Kenwood to be about 90 minutes using alkaline batteries with a 1-minute-TX/3-minute-RX cycle. How this relates to NiCd usage I don't know, but in my experience with a 1-minute-TX/3-minute-RX cycle, my batteries lasted about half an hour. Of course, I spend most of my time just listening, which made the batteries last considerably longer. I strongly suggest you use the DC-21 or some sort of outboard dc converter to save your batteries when you operate from the car or from home.

Here in the shack, I hooked up a Mirage C22 amplifier I had from a previous project to a dc power supply and connected an LM-317 adjustable regulator to the DC-21 battery connection. I set the voltage at 8 volts and ran the output of the TH-31AT into the Mirage amplifier. This feeds a KLM 7-element yagi on one of my two masts, and does an exemplary job of accessing local repeaters.

The TH-31AT is configured for simplex, −1.6-MHz offset and +1.6-MHz reverse offset, selectable from a tiny switch on the back panel. You shouldn't try to change the configuration while you're driving, however. Nor should you try to change the thumbwheel frequency selector while in the car. The Japanese must have incredibly tiny fingers! The thumbwheel isn't backlit, so you'll need to change it by feel in the dark or under low-light conditions.

The receiver is rated at 0.5 uV for 12-dB Sinad, and I wasn't in a position to challenge this claim. The unit is sensitive. It compares favorably with my Microwave Module, which has a MOSFET front end. Squelch sensitivity is rated at less than 0.2 uV and, again, I wasn't in a position to challenge the claim. The antenna connector is somewhat unique: It's a threaded RCA connector! I'm not sure why Kenwood settled on this type of plug, as a BNC jack really wouldn't have used any more room. Perhaps it's because the RCA connector presents a lower profile. But it will play havoc with an external antenna unless you purchase the AJ-3 adapter (threaded RCA to BNC female). With the AJ-3, you can use mobile antennas or hook into an external power amplifier.

Other features include an optional tone module for tone burst (TU-6), which is activated by a top-cover switch. The thumbwheels

tune in 1-MHz, 100-kHz, and 10-kHz steps, with a +5-kHz switch next to the tone switch. An LED keeps track of battery life and goes out when the voltage drops too low. Finally, connections for an external speaker and a microphone are found on the top cover, and Kenwood supplies an external speaker/mike (SMC-30) as well as a headset with VOX (HMC-1). Unfortunately, the plugs are reversed from the ICOM speaker/mike's and spaced further apart, so you can't cheat with another unit. Alkaline battery packs, a heavy-duty pack (SUM-2), and a charger round out the accessories. Boy, this can get expensive!

Operation

Now for the hands-on critique. The size definitely takes some getting used to. The controls are so tiny, for example, that you really have to look carefully to make sure you have selected the right offset. I'd also feel comfortable with a somewhat more responsive DTMF pad, as there is no tactile "click" when you depress the keys. Another complaint is the pressure needed to keep the PTT switch fully depressed. I have been in the middle of a QSO when the PTT dropped out on me, since I hadn't been maintaining a steady pressure on the switch. Again, this is due solely to the lack of a positive feel when depressing the switch. Whether this is a problem due to the size of the rig, I don't know.

The audio output is more than adequate for hand-held use (250 mW across 8 Ohms) but is not going to hack it in noisy mobile operation. An outboard power-amp module would be called for here. I use the unit barefoot into a Larsen 5/8-wave antenna with the DC-21 dc adapter and can work many repeaters full-quieting. This may be due to the fact that several of them have GaAsFETs in the front end, but, whatever the reason, it makes mobiling a pleasure. Since the radio isn't much larger than my Kenwood MC-45 microphone for my TR-7400, it's more like using a microphone—not an HT. Best of all, if you have to park your car in an unsafe area, the unit and dc converter can go in your coat pocket or briefcase. In fact, the TH-series HTs are ideal for traveling in general!

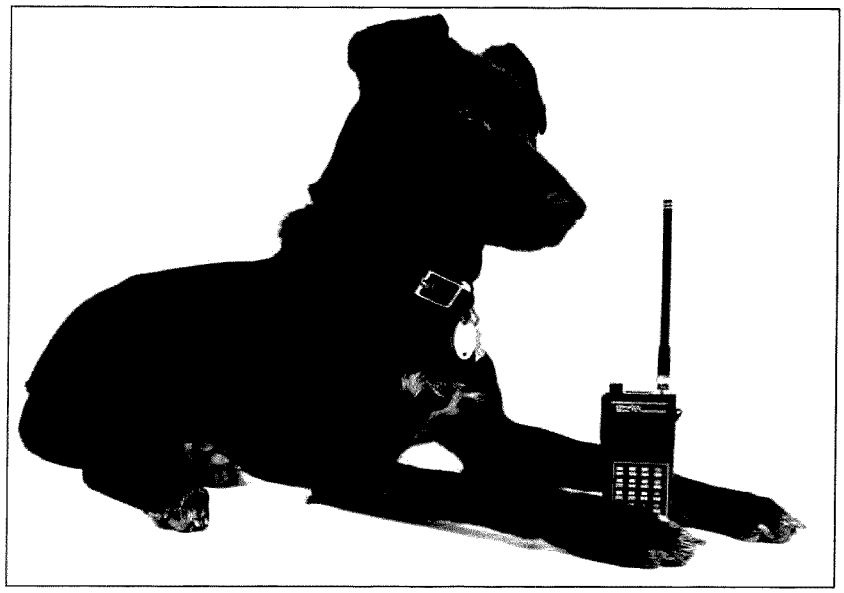


Photo B. "Crescent," my Labrador Retriever shows relative size.

To summarize, the Kenwood TH-31AT is a fun, easy-to-use radio for 220-MHz FM, although the controls may take some getting used to. The wide range of accessories makes it very adaptable for mobile and base-station operation, but you're likely to forget where you left it last due to its size! I suspect this would be a very popular radio with Novices should they ultimately get 220-MHz privileges. As for myself, the biggest problem is keeping the dog from using it as a toy and remembering not to sit on it when it's in my back pocket. One outstanding application for me is to use this HT as a low-power 220 communications link at large hamfests, such as Dayton, since the whole thing slips unobtrusively into a shirt pocket and the earphone is the only external connection. I also understand that Kenwood has now come out with a quick-charger that can hold two packs, and this can only add to the functionality of the radio.■

Heathkit HD-3030 Interface

by Marc Stern N1BLH

Heath Company
Dept. 150-735
Benton Harbor MI 49022
$199.95

There's an old saying in our ranks that goes something like this: "If you want to learn about the hobby, build something." It's a saying that had validity 30 years ago and that is still true today, to a large extent.

Of course, the kits of 30 years ago were large and complex and were state-of-the-art for the time, but they were kits you could really get your hands on because of the tubes and large components used. Contrast this with the kits of 1986, which feature integrated-circuit technology and printed circuit boards stuffed with tiny components. The difference is like day and night.

But, while it may not now be possible to build and debug each circuit—many of them are contained within IC flatpacks—kit building still gives you the chance to learn how a component functions within a specific overall device and how to handle IC components without fear. That, perhaps, is today's greatest lesson with kit building.

Thirty years ago, of course, one could attack each part of a circuit, check its performance, and improve on it. This was due to the nature of the components used. To a large extent, this defined the saying about kit building and learning. But those days are gone, and perhaps the primary reason anyone builds a kit today is not so much for a learning experience as for fun.

This is why I recently undertook the building of the Heathkit HD-3030 RTTY/CW interface. I enjoy kit building and wanted to add something to my shack that would increase its versatility, which the 3030 has done.

There was another reason I chose the 3030: It has been a couple of years since I last built a kit—no time really—and I wanted to handle something that wasn't overly complicated but that presented enough challenge to keep my interest. The 3030 came through with flying colors on both scores.

Organization

As you would expect, when the 3030 made its appearance here, I immediately ripped the box open and checked things out. The first thing I noticed was the organization. When I built my last Heathkit, everything was loaded into the box in a manner that made little sense. I had to sort through boxes and bags of resistors, capacitors, and diodes, as well as hardware and other goodies, and set things aside. Then I had to check everything against the manual, which was time-consuming.

The HD-3030, on the other hand, came well organized. The major subsystems were packaged together in the box, so all I had to do was

Photo A. The Heathkit HD-3030 RTTY/CW interface.

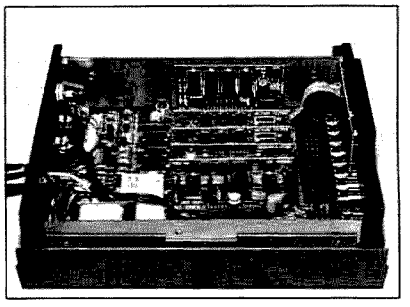

Photo B. The HD-3030 with boards intact.

move from subassembly one to seven, checking the components as I went. I then left each subsystem in its cardboard divider and went to work. This organization made things much easier, and I was able to jump into building this device quite quickly.

Construction

The first task was building the CW and RTTY demodulator boards, as well as the AFSK generator and the 2125- and 2295-Hz-shift boards, which give the 3030 its standard 170-Hz shift. These daughterboards are meant to plug into the motherboard via a 15-pin connector.

These boards took me about five hours to finish. I probably could have done them more quickly, but I took my time, not wanting to hurry things. Next, I moved on to the motherboard, which took me about another five hours in total.

At this point, I put the box together, made the required mechanical connections, and put the 3030 through its first smoke test. And, just as you'd expect, the smoke leaked right out of the device on the first go-around. I retraced my steps and everything looked as if it was correct, so I tried it again. This time nothing happened.

Well, I had to make the first of several calls to customer support. After I told them the symptoms and the findings of my own troubleshooting, they diagnosed the problem as lying in the voltage-regulator section. (Actually, I isolated the problem to one of the three regulators—7805, 7812, 7912—fairly quickly, and the customer service technicians at Heath confirmed my diagnosis, although none of us could figure out exactly what was going wrong.)

The upshot of this was that the call produced replacement components which were shipped promptly. The funny thing is that the same component kept on blowing all the time—the 7912—and although everything looked correct, it really wasn't. As I looked at the documentation for what seemed the thousandth time, I noticed there were two nylon screws included with the kit, but only one had been used. As I looked further, I noticed that one was supposed to have been used with the 7912. So, as usual, pilot error crept into the picture. When I put the new 7912 into position and replaced the metal screw that had caused the short with the nylon screw, the 3030 came to life.

Following the manual—once I had the device working, that is—I quickly aligned each board and set the 3030 up to work. Like all Heathkits, the manual is comprehensive and presents not only the building instructions, but also setup, alignment, and theory of operation. The documentation also includes a comprehensive breakout pictorial of each major subassembly and its construction, as well as a block diagram and schematic diagram. There are also X-ray views of each board.

Operation

Overall, the HD-3030 is a very competent interface with a good set of specifications. For example, the center frequency of the CW demodulator is 750 Hz, while the −3-dB bandwidth is 70 Hz. The −20-dB bandwidth is 240 Hz.

The 3030 is a universal interface in that it will work with a variety of personal computers. It just depends on the software you're using to drive it. Heath offers its own software, compatible with the H-8 and H/Z-89 computers, and many other programs are available for other personal computers. I used the 3030 with a public-domain IBM Personal Computer program, and it performed quite well.

Tune-up is easy thanks to the multi-segment bar-graph display. The front panel also controls choice of CW or RTTY and shift selection. The built-in shift is 170 Hz, although 425- and 850-Hz-shift boards are available as options, as is a preselector board that increases the sensitivity of the unit.

The 3030 is also compatible with TTL or RS-232 voltages, and a loop supply is a user option. The rear panel contains connectors for ground, an auxiliary ac output, the loop, and the interface connector.

The interface connector is a standard miniature DB-25 connector that Heath has used for its own purposes. It provides three RS-232-level outputs and inputs, as well as TTL-level outputs and inputs. There are also scope outputs for mark and space.

Altogether, I was quite impressed with the unit and the way it fit into my shack. But, there are a couple of aspects that I must comment on—the interface connector and the option boards.

Although I have no problem with Heath using a serial-type interface connector on the 3030 (a DB-25), I do have a problem with the way some of the input and output lines were implemented. Using the same connector for both inputs and outputs means you will have a tough time putting a cover on the connector body. The reason, quite simply, is the necessity of extra wire coming from the connector so that you can key the rig for RTTY or CW. It wasn't an easy task to cover the connector without crushing the wires. It would have been better if Heath had opted for RCA or phone-jack connectors for these outputs.

And I think Heath is unwise in offering the 425- and 850-Hz-shift boards as extra-cost options. In fact, I suspect this will probably hurt sales more than help because other units on the market are less expensive than the HD-3030 and offer the "standard" 170-Hz amateur shift and the commercial 425- and 850-Hz shifts as part of their packaging. You don't have to add it later or pay extra for it. In fact, other less expensive units have variable shift to 850 Hz. So, if you're thinking of this unit, be aware of the necessity for these optional boards, although I did find it will function quite nicely without them by using the mark frequency and tuning around it.

Overall, the HD-3030 is a competent unit that does offer a learning experience. No, you won't learn all about the hobby from it, but you will learn about parts of it and about the proper handling of integrated-circuit technology, something we must know in this day of microprocessors.

How To Build A Great Ham Club

When ham club meeting night comes along, do you have a problem with priorities? Should you go to the club meeting or the dentist? Or perhaps a visit to your mother-in-law? Tough decision. The answer is to get the heck down to the club meeting and get the club off its collective ass. You can make the club so much fun the members will be fighting to have weekly meetings instead of monthly. Now stop sitting there wringing your hands, hoping someone else will do it.

Yes, I do a lot of things. You know why? Well, every time I look around and say to myself, gee, someone really should do something about so and so...I realize that, heck, *I'm* someone. So I go ahead and do it. It's amazing how much you can get done when you decide to do it.

For instance, I've been writing about your taking off a few weeks in October and coming on a little DXpedition to Asia with me. You know it would be a lot of fun, but you aren't into making big decisions like that. Phooey. Sure, I know, you're a bit tight on money—and you don't know if they'd let you take that much vacation. I'm sure you can come up with a half-dozen good reasons for not doing something. My friend, you only have one trip through this life, so isn't it time you started making some decisions which will add to your life? I'm going to have a ball in Asia and you should be there with me having fun.

Show Biz

Okay, let's apply that concept to getting your ham club going like gangbusters. I said to stop wringing your hands—let's get to work on this. The first thing you have to understand about ham clubs...about any clubs...is that you're in show business. It's basic—if the members don't have fun they aren't going to come back. Think about it.

What's fun to do at radio club meetings? One fun thing is to get to talk with your fellow hams. Have you built that part into your club meeting? Give 'em some refreshments about half way through the meeting and maybe twenty minutes to chew the rag. Coffee and assorted doughnuts are good fare...or fresh cider and doughnuts. Have you an XYL or two in the club who can make a homemade coffee cake?

A meeting can be made fun if you can find a good speaker. Is there a ham manufacturer or dealer within reasonable commuting distance of your club? Ask him to come in to show and tell the members about his product.

A hint on the care and feeding of speakers...take care of them and feed them. Get maybe three or four members of the club to have dinner with the speaker before the meeting. Pay for his dinner, you tightwad. If you're driving him to the meeting from the restaurant, you might have a two-meter rig in the car with the members talking up the meeting over the repeater. This will give him the impression that you have a live group.

"At least one club member must have a Macintosh by now. Quickly elect him editor of the club newsletter."

Once you're at the meeting place be sure that many of the members come up to the speaker and introduce themselves to him—perhaps with some compliments on his product. Get him off to a good positive start. I hate to think of how many club meetings I've been to where the members all were busy talking with each other and ignored me completely. Start the meeting on time.

How do you get the slow arrivers to stop straggling in late? Hold the door prize drawing first instead of last. A couple times missing the drawing and you'll find 'em remarkably punctual.

If you really must have a business meeting, keep it to under ten minutes. You should do this anyway, for nothing kills a club like extended business meetings. No good can come of it. Let the executive committee handle the business and give the club a fast report.

If you want your speaker to be interesting he has to be the star for the evening. Get him on early. Take the time to give him a good introduction. Give him any help he needs to demonstrate his product.

If you've a shortage of ham industry people in your area you should look around for ham fanatics to show and tell. Check out your members for any known DXers, packeteers, SSTVers, RTTYers, moonbouncers, meteor scatterers, microwavers, OSCARers, certificaters, contesters, builders, traffic handlers, and so on. Lift up the local rocks and see what crawls out.

I've seen some great DXpedition slides, and heard interesting talks on just about every ham fetish. They're out there if you'll beat the bushes. And don't dump the problem on the program chairman...get the whole club to scrounge.

Can you get some Novices and Techs to come to the meeting a half hour early for a short technical talk and perhaps ten minutes of code practice? This is a good way to help newcomers get licensed—and club members move up the ladder more easily. The club has to be fun...but it should also be supportive of the members. The club is where you provide the peer pressure to get 'em to get a higher class ticket. It's where you get more and more members to try new aspects of the hobby.

Keep 'em Short

Now, after the speaker and the Q&A...and then after the feeding frenzy...it's time for some reports. Short reports. This is the time for the TVI committee to report on its activities...the licensing committee on new and upgraded licenses...the school radio club Elmering committee...the self-policing committee on recent complaints...the program committee on upcoming entertainment...news of club activities such as an auction, flea market, picnic, mountaintopping party, Field Day effort, and so on. How about organizing groups to drive in a caravan to major hamfests and conventions?

At least one club member must have a Macintosh by now. Quickly elect him editor of the club newsletter. Help him set up the reports

he's going to need and the deadlines for the reports. You want to build interest in ham activities so get in reports on packet action, DXing scores, contest scores, antenna erecting parties, OSCAR contacts, and so on.

Does anyone in your club have a video camera? Great! Get him to do a video of the club activities. Get him to visit members and make a video of their stations. If the club has some fox hunts you can make a fun video of the hunters. If you don't have fox hunts, why not? A short video will brighten up a meeting. If you don't have someone with a video and another member with a Macintosh in your club, you're badly in need of some new blood.

Growth Mode

How can you get new members? Easy... the club newsletter is a good sales tool. Get someone with a computer to make a list of every ham in the *Callbook* in your zip code areas and start sending them the newsletter for perhaps four issues with an invitation to come to the next meeting. You might even tell them what fun they will have when they come. Remember, as I said, you're in show business now. Once you get them to their first meeting, be sure you have a committee to spot them and make a fuss over them. Introduce them during the meeting. Make them special and they'll be back.

You can't afford to send free newsletters to a zillion inactive hams, so rotate the free copies as you can afford. It wouldn't hurt to have club members take lists of the potential members and give them a call with a personal invitation to come to a meeting.

At meetings you can ask members to make a list of every ham they hear in the area who should be invited. This will help you pick up many which aren't listed in the *Callbook* yet. It'll give you a first-class mailing list, too. These chaps are active hams, so they'll probably be an easier sell than someone who hasn't turned on a rig in ten years. Make sure club members talk up the club on the air and invite everyone they talk with on the air to the next meeting.

Be sure to put a small poster in any local ham dealer store. You'll want to have posters in the local high schools, too. Your newspapers will list your meetings, complete with a short story on your speaker. Cut out a copy for the speaker and give it to him. It'll help his ego.

Does your neighborhood have any bulletin boards? Get your posters up there, too. How do you make posters? Get that kid with the Macintosh, he'll be happy to oblige.

Have you thought about organizing some club outings? You might get a group together to visit a TV station... an observatory... an electronics plant... an FAA station... a research lab. You'll probably find at least one member with an in for such a visit.

Now Get Going

Okay, I've primed the pump... now I expect you to take the ball. If you have any ideas on how to get clubs perking, send them in so I can pass your ideas along... and give your club some credit.

Oops, I almost forgot. If I'm speaking at a club I ask for no smoking... and generally get a round of applause for it. Why not ask your nicotine addicts to indulge in their drug habit outside? Nicotine is a poisonous oily substance gotten from tobacco leaves... named after Nicot, a French diplomat who introduced the drug to France.

I've run into a few clubs who encourage the use of alcohol, passing around cans of cold beer. Another drug with millions of addicts. Let's keep drugs out of club meetings... alcohol, nicotine, pot, and cocaine. Why do kids think it is so cool to be drug addicts? Phooey... none of these drugs are going to improve your meetings.

I'm going to get working on some videos of my talks which might help fill in a few minutes for your meetings. I'll let you know as I get 'em ready. I've got a couple of the new 8mm cameras, so it won't be difficult. I'll do 'em on 8mm and then dub them to VHS for you.

If your club can put together an interesting video you might let other clubs know you have it available via *73*. I've seen some remarkable home movies of club activities in the past... now it's time to do these with video so we can inexpensively distribute them. What can your club do which will make an interesting video for other clubs and for showing at hamfests?■

Roll A RTTY Scope

An oscilloscope is still the best way to lock on to a teletype signal. Building one is easier than you think!

One of the most common complaints voiced by newcomers to radioteletype is difficulty in tuning the signal. It doesn't take long to realize that watching a couple of flashing lights and tuning for "good" copy is, at best, a haphazard method.

Over the years a number of schemes have been introduced to aid the tuning process, including dancing meter needles, LED bar displays, and various forms of digital and analog converters. Compared to the old reliable oscilloscope, however, they seem to leave a lot to be desired. The scope can tell the accuracy of the received shift. It will also give a very accurate indication of the tuning. For those of us who prowl the commercial RTTY channels, the scope is invaluable. It will, for instance, show at a glance the difference between a 375- and a 425-Hz-shift signal. In spite of the simplicity and accuracy of the oscilloscope, it is amazing how many RTTY operators have never used one.

Of course, it must be said that the oscilloscope will not work with all RTTY demodulators. Demodulators or terminal units (TUs) that do not have separate mark and space channel filters cannot use a scope for tuning purposes (at least not in the form described here). How can you tell? Look for output connectors labeled "oscilloscope" or, failing that, look at the schematic diagram. Nearly all demodulators that have separate mark and space channels or filters will be similar to the block diagram in Fig. 1. Older units may

Photo A. Left to right: surplus CRT shield and mounting bezel, 2-inch CRT, 3-inch CRT.

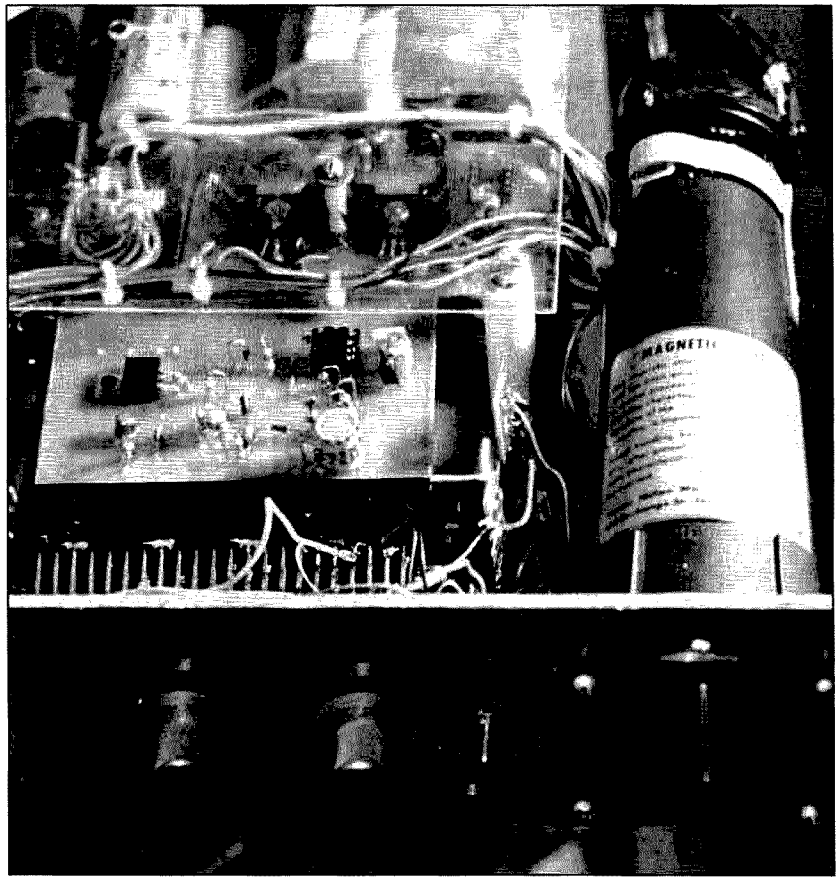

Photo B. The RTTY scope mounted in a home-brew TU.

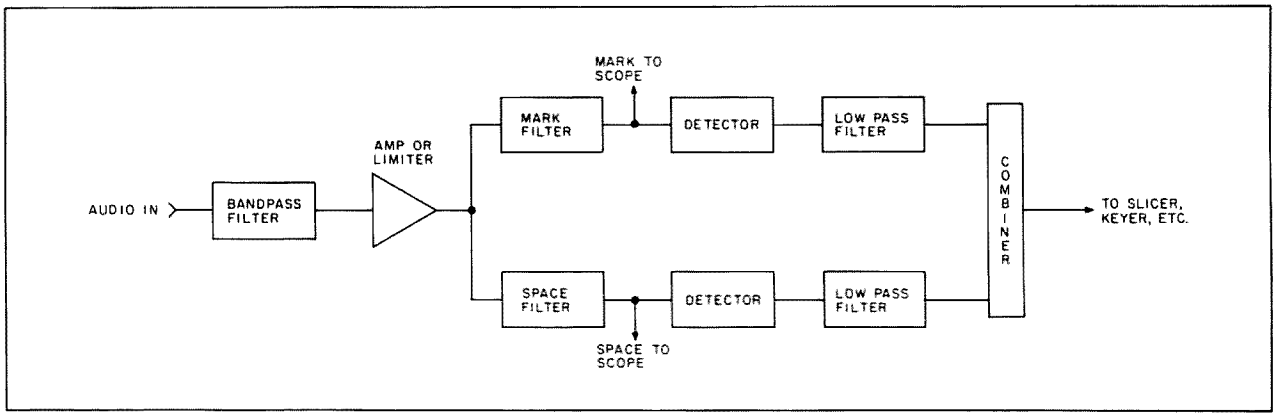

Fig. 1. Block diagram of the audio stages of a typical RTTY demodulator.

have toroidal coils and capacitors for the filters rather than operational amplifiers or switched capacitors, as is the current trend. In either case, the important thing is separate filters for mark and space. Some demodulators will have more than one space filter, the other filters being switched in when tuning different shifts.

Adding a Scope

Assuming that your TU can use a scope, there are two ways to go. The easiest is to hook up a standard oscilloscope. They can usually be found for $5 and up at swapfests. Nothing fancy is required. The only important thing (other than it being in working order) is that the scope have an external horizontal input. Nearly all do.

"In spite of the simplicity and accuracy of the oscilloscope, it is amazing how many RTTY operators have never used one."

The space-filter output is coupled to the scope's vertical input, and the mark-filter output is fed to the horizontal input. I have had no trouble doing this using plain hookup wire. However, it would probably be wise to use shielded cable. Place the scope's horizontal control in the external position. If the TU has a limiter, turn it on.

With the scope and demodulator turned on, adjust the scope controls until a dot appears in the center of the scope tube. Now feed a mark signal into the demodulator. You should see a horizontal line on the scope tube. If not, then adjust the horizontal gain until a line appears across the face of the tube. Many scopes are a bit short on horizontal gain, and you might find that the trace will not cover the entire face of the tube.

Next, feed a space signal into the TU. A vertical line should now appear on the scope. Adjust the vertical gain until the line is the same length as the mark display.

That's all there is to it. When tuning in a RTTY signal, the lines on the scope will assume a more oval shape due to the mark and space filters. The narrower the oval is, the narrower the filters being used (assuming no change in shift).

Roll Your Own

The second way of adding a scope to your RTTY setup is to build your own. It is neither difficult nor costly. Your own scope will have the advantage of being smaller than a regular oscilloscope, which means it can be built inside a present TU.

A basic RTTY scope consists of the CRT (see Photo A), centering controls, horizontal amplifier, vertical amplifier, and power supply. The actual scope circuit (see Fig. 2) has

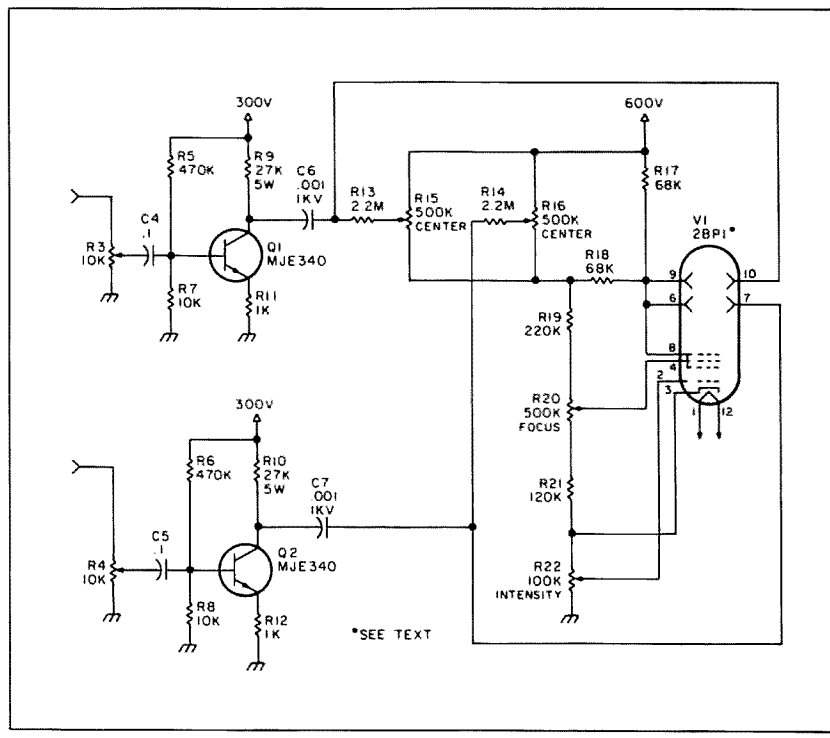

Fig. 2. RTTY tuning scope.

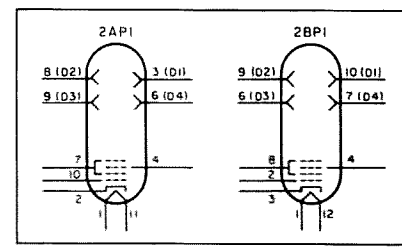

Fig. 3. CRT basing diagrams.

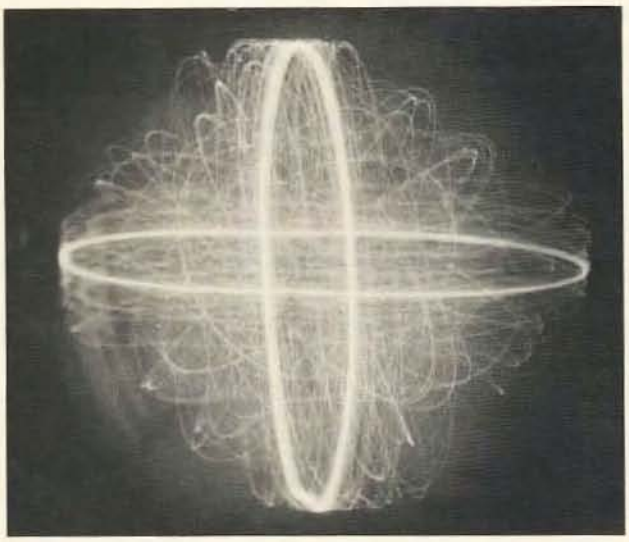

Photo C. A 170-Hz-shift RTTY signal, as displayed by a scope. Compare this with Photo D.

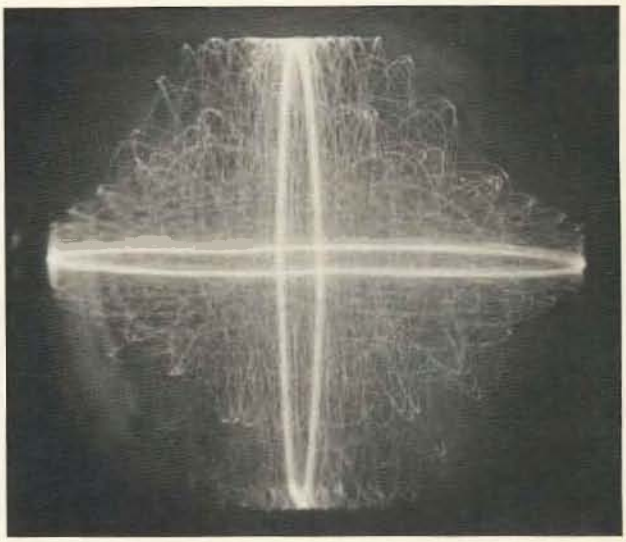

Photo D. A 425-Hz-shift signal. The filters used have the same bandwidth and gain as those used.

been around for years and is a standard with old-time RTTY fans.

Amplifiers Q1 and Q2 are required because the output of the demodulator filters is not great enough to give adequate CRT spot deflection. With the power-supply voltages given, the two one-transistor amplifiers used in the circuit have more than enough gain for full deflection when driven with op-amp-type filters having outputs greater than about 3 volts peak-to-peak.

Because the scope input impedance is somewhat low, it could cause undue loading of the filter and detector circuits of some demodulators. This could be overcome by adding a high-impedance voltage-follower stage to drive each amplifier.

A word of caution: The voltages in this circuit are dangerous and a simple accident could be fatal. *Use extreme care.*

Parts

The CRT shown is a 2BP1, but a 2AP1 will work just as well—though it has different pinouts and requires a different socket. Fig. 3 shows the basing diagrams for the 2BP1 and 2AP1.

The 2B-- series CRT was manufactured with several phosphor types, including P1 and P11. The P1 phosphor in the 2BP1 is the common green. The rarer P11 (2BP11) yields a blue trace. There is no other difference between the two CRTs.

The CRT you use will most likely be determined by availability. Small CRTs are sometimes hard to locate. If you happen to locate a 1-inch tube, then use it. Some 3-inch tubes can be used, but they are longer and take up far more space than is really necessary.

Finding the necessary components will probably be the most difficult part of building the scope. In this day of solid-state and microcircuits, higher voltage and power components are expensive and sometimes hard to locate. A quick check showed the 2BP1 priced from $10 to $75 in "used" condition; so if you buy the parts, careful shopping is advised. Many times you can locate a surplus scope foundation for a price that is less than the cost of the CRT alone. Some used CRTs may show trace burns, but unless the burns are serious the tube is probably still usable.

While a mu-metal shield for the CRT is not absolutely necessary, it will protect the scope display from being distorted by stray magnetic fields associated with the power transformers. The shield also simplifies the mounting of the tube. A surplus scope foundation will have not only the tube and shield but also the socket and usually a mounting bezel. These can be removed and placed in a new box or panel, making an attractive display.

An alternative would be to make a bezel from a circular meter by removing the meter movement and the back of the case. Replace the meter glass with green plastic. A separate shield can be purchased from a surplus dealer.

Care should be exercised when inserting the CRT in the socket. Many of these older tubes suffer from poor bonding between the glass envelope and the Bakelite™ base. One wrong twist or push could ruin the tube.

The collector load resistors in the vertical and horizontal amplifiers should be 5-Watt units. They do get warm and should be mounted in a reasonably open space.

Since the scope draws so little current, only half-wave rectification is used in the power supply (see Fig. 4). Transformer T1 secondary voltage is not very critical and just about anything between 150 and 250 volts each side of center tap will work. The low-voltage output from the power supply should not be greater than 300 volts, otherwise the

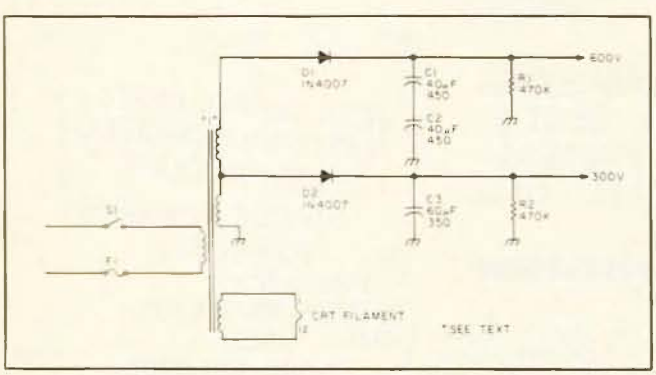

Fig. 4. Power supply.

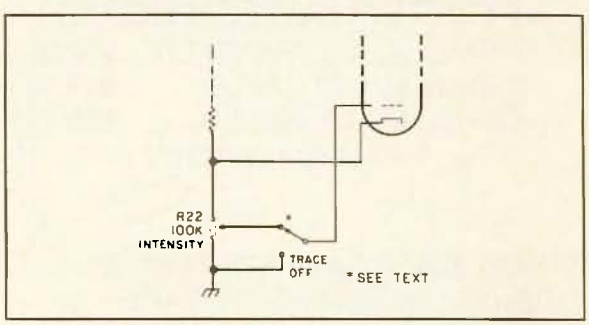

Fig. 5. Optional circuit to turn off scope trace

ratings of the transistors may be exceeded. A transformer from an old tube-type radio will probably work fine. The one used here came from a defunct chart recorder. If the T1 chosen has a 6-volt filament winding, it can be used for the CRT (assuming the CRT has a 6-volt filament) rather than using a separate transformer. Both the 2AP1 and 2BP1 have filaments rated at 6.3 V at 0.6 A. (Don't overlook the possibility of tapping into the transceiver's high-voltage supply—if it has one.)

The value of the power-supply filter capacitors given in Fig. 4 is just about the minimum that can be used. More would be better. Be sure that the voltage rating is greater than the supply voltage. Some series-parallel combination will probably be necessary to achieve the needed values. If, after building and testing, the scope trace shows some ghosting, then an increase in the low-voltage filter capacitance is necessary. I started with 30 uF but found that 60 uF gave a better trace.

Only the intensity control needs to be mounted in a convenient place. Once the other controls are set, they should not need to be adjusted again; thus, they can be mounted inside the unit. The intensity control can be backed off during standby periods, preventing burning of the CRT. As an alternative, a DPST switch can be wired across the intensity control to turn off the trace during idle periods (see Fig. 5).

Nothing in the circuit is critical, so just about any layout and construction method can be used. The transistors should have heat sinks. Don't forget to use heat-sink compound and insulating kits. Remember, there are up to 300 volts on the collector of each transistor.

It is a good idea to locate the transformer as far away from the CRT as possible. If the CRT trace is distorted by stray magnetic fields from the transformer, try rotating the transformer slightly.

Tune-Up and Hookup

Tune-up is just as before, although at this point it makes little difference which amplifier is mark and which is space. After connecting the scope to the TU (Photo B), set R3 and R4 to the middle of rotation and adjust the scope controls for a fine spot in the center of the CRT. If the spot does not focus to a fine dot, then it is probably being distorted by stray magnetic fields from the power supply.

Now feed a mark signal into the TU. A line should appear on the CRT. The line will probably not be horizontal but rather at an angle. Loosen the CRT mount and carefully rotate the scope tube until the line is horizontal. Adjust the associated gain control until the line crosses the entire CRT face when the input signal is maximum. Any further increase in the input signal should not cause the CRT display to expand.

Using a space signal, adjust the remaining gain control in the same fashion for a vertical trace. The RTTY scope is ready to use.

Parts List

C1–C3	60 uF, 450 V, electrolytic (see text)	$6.00
C4–C5	.1 uF, disc ceramic (RS 272-135) (J)	.59

The Display

Over the years, numerous drawings and an occasional photograph have been published showing the patterns displayed by a RTTY scope. Unfortunately, many of these are based on a "perfect" system; they sometimes have little resemblance to the traces seen in real life.

What the scope shows is, of course, determined by the filters in the TU and the shift being tuned. The wider the filters or more narrow the shift, the more oval the scope traces become (see Photos C and D). This is caused by lack of complete mark and space channel isolation.

The scope also will show a number of faint traces around the main ovals. These traces are caused by the mark-space frequency transitions of the received signal; the change from mark to space is not instantaneous. The narrower the filters or the higher the keying speed, the more pronounced these secondary traces become. Since minimum usable filter bandwidth is directly related to the keying speed, a point can be reached where the scope will not give an adequate display for tuning. But the TU could not handle the signal anyway.

Ideally, when a signal is properly tuned the ovals will form a perfect cross. However, if the shift being received is not quite accurate, then when the mark signal is properly tuned the space trace will not be perpendicular. Instead, it will be rotated clockwise if the shift is too narrow, or counterclockwise if it's too wide. (Some commercial scopes will show an opposite rotation.)

Also, some filters and limiters introduce phase shifting, making a perpendicular display nearly impossible to achieve. Another form of phase shift produces ovals that look more like figure eights. In my case, this latter form of phase shift is caused by over-driving the input of the TU and is easily cured by turning down the receiver audio.

If the phase shift is taken into consideration, the scope will still work quite well. Of course, phase shift can be corrected by the addition of a "phaser circuit," usually consisting of a resistor-capacitor combination in series with the scope input.

Monitoring your own signal and using the scope as a spotting indicator is a good way to make sure you are on the other station's frequency. With the use of MSO operation, this is very important.

After a few hours of using the RTTY scope, you will probably wonder how you ever got along without it. ■

CLUBS

Joseph Nardo WD6R
231 Timber Road
Newbury Park CA 91320

Bozo And The B-Hunt

Want to light a fire under that snoozing group of old-timers you call a club? Want to put some fun back into ham radio? Want free beer? Read on.

You are likely to hear some very strange transmissions if you are traveling through Southern California monitoring the WA6OBT 147.285/.885 repeater. How strange? Here are three recent transmissions:

"The music stopped; the lady died."

"If you are near the Inn, you can see my grin."

"A man was convicted of a crime; the judge set him free; you would have too."

As you listen more carefully, you begin to hear many questions being asked in rapid succession. Only a simple "yes" or "no" is heard in response. The questioning becomes so heavy that stations are heard doubling or tripling with each other as each excitedly tries to ask a question.

"What in the world are you listening to?" your companion asks.

You have just encountered either an exciting B-hunt in progress or the challenging Riddle Night, two very popular activities which have sprung up on Larry King's repeater (known affectionately as Bozo).

In just a few months, these unique activities have renewed old companionships, introduced new friends, and are providing an opportunity for members of the Conejo Valley Amateur Radio Club (CVARC) and other users of the WA6OBT repeater to meet on a regular basis both on the air and in person.

The Birth of the B-Hunt

Locating hidden transmitters via use of two-meter amateur radio, more popularly known as T-hunting, is a sport which has been around a long time. The object is to find a hidden transmitter through the use of a special direction-finding antenna, attenuators, a map, and a compass. A keen sense of direction, a competitive spirit, and a calculating mind also help. The traditional T-hunts have been a monthly event in the Conejo Valley area.

During a discussion on the air one evening, I offered a challenge for a different type of T-hunt. Instead of the usual equipment, a different set of skills would be required to locate the hidden transmitter. A series of clues would be given which, when solved, would lead the hunters to the hidden transmitter. The first operator to find the transmitter would be treated to a beverage of his or her choice, hence the name B-hunt.

> ***". . . the company of friends and famiiies was the best part of a creative hunt."***

The response was quite positive as the word spread of the upcoming activity.

"When is the B-hunt going to start?" was heard as stations gathered on the specified evening. People were actually showing up to participate!

The hidden transmitter operator finally announced his arrival on frequency. The rules were read and the first clue was given.

There was no hesitation as questions began to fly in an effort to solve the clues as quickly as possible, with each participant trying to be the first to locate the hidden transmitter. Clues were given every five minutes. A new clue was given only after the previous clue was solved.

Within approximately thirty minutes a winner arrived, a husband and wife team, no less, to find the hidden transmitter in the parking lot outside a local watering hole. It was decided to use the parking lot for the first hunt since it might have been a disturbing sight to see someone sitting inside the establishment talking into a "police-type" radio, suspiciously responding yes or no over and over.

The hunt continued for the other participants. Once the hunters moved inside, the owners and other patrons became quite interested in the activity, asking many questions about the hunt and amateur radio.

From B-Hunts to R-Hunts

B-hunting proved to be an instant success. Another hunt was quickly scheduled for the next week, with the winner of the first hunt responsible for "hiding" the next week. At the conclusion of the second B-hunt, there was a discussion about expanding the hunts to include XYLs and other family members. The B-hunt quickly changed to an R-hunt, a restaurant hunt.

When the R-hunt began, wives, children, and friends joined in the fun. Again, the rules were reviewed. Clues were given and eventually solved, and we all wound up at the local pizza parlor, enjoying good food and company and swapping "war stories" of the hunt.

LMNOP Night

The B-hunts and R-hunts not only grew in popularity but also soon generated some very creative thinking. Finding new locations along with developing challenging clues was turning out to be as much fun as the hunt itself and led to a new wrinkle, an LMNOP Night.

Curiosity over what an LMNOP Night might be caused much speculation. Inquiries and guesses flourished on Bozo. One operator thought he actually had it figured out long before the event was to take place.

Hunt night finally arrived. Many anxious operators were awaiting the first set of clues. The hidden operator announced his arrival. The rules were reviewed and the first clue was repeated: "LMNOP."

After approximately one hour and dozens of questions, LMNOP was finally unraveled—"Light Meal Night On Potatoes!"

That was only the beginning. Somewhat mistakenly, the questions centered around attempting to identify a specific restaurant which specialized in potatoes. There are restaurants that specialize in pizza, pancakes, fish, or hamburgers, but potatoes? That was a tough one!

Additional clues were given:

"If you are near the Inn, you can see my grin" was quickly cracked by one operator. Soon, the first arrival was announced. The search continued with additional questions and clues; each succeeding clue was a little more revealing and helpful. Other arrivals were announced.

Finally, the last clue did it for the less fortunate hunters:

"Some call it home; ever be it so humble; it may not be neat but ever so sweet."

The "restaurant" was not a restaurant—it was the home QTH of Ray WB6HDG and Nancy WA6PRW Biederman. And what a delightful meal it was, of potatoes, sour cream, chives, cheese, wine, vegetables, etc. Again, the company of friends and families was the best part of a creative hunt.

And Riddles, Too!

"Riddlistics" is generating considerable interest and participation on Bozo, too; it began almost simultaneously with the unusual alphabet hunts. One evening I asked if there was interest in solving a riddle. The adventuresome group replied, "Let's go!" I gave the riddle:

"The music stopped; the lady died."

As with the hunt clues, only yes or no questions could be asked, with the object being to figure out the situation described by the riddle. After approximately two hours and nearly 100 questions, the riddle was solved.

The solution? This riddle describes a circus act in which a blind female tightrope walker uses the music of the band to tell her when she is at the end of the rope walk. When the music stops, she knows she can then safely step onto the platform which is directly in front of her. Unfortunately, one evening the music stopped a few beats early and, thinking she was at the end of her walk and near the platform, she stepped off early and fell to her death.

Riddle Nights not only challenge local hams but they attract other hams from neighboring communities. Mobile operators passing through the area have joined in as well. Riddle Nights now occur at a moment's notice. Some riddles have been solved within five minutes. Others have taken several hours. Any riddle is welcomed. Some have been quite challenging. Others have bombed.

Some Simple Rules

To make the activities both challenging and enjoyable for all participants, a few simple rules have been developed:

Foremost, all proper conventions of legal operation must be observed. Timely station identification is a must at all times.

The repeater always remains available for emergency traffic or other regular use, as needed.

Good taste is always practiced.

Only questions which require a yes or no response are permitted for both the hunts and riddles.

Questions regarding geographical locations are not permitted for the hunts, e.g., "Are you east of Main Street?"

No direction-finding equipment is permitted.

For the hunts, approximately seven to ten clues are prepared and given in decreasing order of difficulty. Developing challenging clues has been as much fun as the hunt itself.

New clues can be given only after the previous one has been solved or clues can be given every five minutes or so to speed up the hunt, if time is a factor.

No one is excluded. Many new friends have been made as a result of the hunts and Riddle Nights.

Locations are not given away by the winners. Once the hidden transmitter has been located, the hunt continues. Everyone is encouraged to find the location. Getting together has been the best part!

If someone solves a riddle quickly, a phone call is made to the "riddle control operator" to check out the answer, thereby not giving the solution away over the air. In fact, one riddle was solved in five minutes by one person and it took others over an hour to come up with the answer. Phone calls keep Riddle Night going for the other participants.

Join the Fun

Riddle Nights and the alphabet hunts are easily adaptable to any community. They may be just the thing your area or club could use to generate some interest among your repeater users and to encourage more frequent friendly get-togethers.

If, by chance, you pass through the Conejo Valley area and are monitoring Bozo (147.285/.885)—be prepared. You may hear a riddle in progress and be tempted to join in. Do so!

Get Started

Interested in getting your area started? How about starting with this very challenging riddle:

"A blind man walked into a restaurant and ordered albatross from the menu. When it was served, he asked the waiter if it really was albatross. The waiter replied yes; the man took out a gun and shot himself."

An SASE will get you the answer. ■

HAMS Against Drunk Driving

A tragedy spurred KB6HQS into action against drunk drivers. He explains how you can use your amateur talents to help clean up the highways.

I am a 17-year-old senior at the Oakwood School, a small private high school near Los Angeles. I have had my Advanced-class license since August of 1985. I have always been fascinated by ham radio, and I've always tried to use my ham skills to their fullest potential. When I started my senior year in September of 1985, many people at my school knew about, but did not really understand, my special hobby. I was looked upon mostly as a "science enthusiast." There was a girl at school with interests totally different from mine—she was enthralled by the theater and the arts, and she wanted to become an actress. Her name was Alexandra Vincent, and she was one grade level below me.

On Monday morning, February 24, 1986, we learned of a tragedy that had taken place overnight. Alex had been traveling on a local freeway at about midnight when a problem developed in her car. She pulled over into the emergency lane, turned on her emergency lights, and then phoned her mother and a towing service. After both had arrived, Alex needed to present her emergency road service card. As she leaned through the front left window to reach for her purse, a white Blazer—driven by a drunk man who had twice before been convicted of drunk driving—crashed into her car and instantly killed her.

It is not possible to write about the grief felt for Alex, or the anger and hate felt for the man who killed her. Everybody at our school was devastated and bewildered by Alex's death, yet the student body soon channeled its negative feelings into the formation of a chapter of SADD (Students Against Drunk Drivers). It was more difficult for me. I felt as if I belonged to the amateur community more strongly than anywhere else, so I wanted to do something using amateur radio to commemorate her, to channel the hate I had for the drunk driver who took Alex's life into something positive. Perhaps ham radio could be used to prevent other people from being killed by drunk drivers.

In the weeks after Alex's death, I devoted all the time I could toward forming a group of amateurs who would voluntarily report drunk drivers on the highway—by relaying reports through base stations to the highway patrol. While this procedure had been going on for a long time, and hams were occasionally reporting drunk drivers, there was no organized effort toward making hams recognize that drunk drivers are a special problem that *can* be dealt with. I wanted to educate my club about drunk driving. Many members were unaware, for example, that every year 25,000 Americans die, and another 1.5 million are injured because of drunk drivers. On weekend nights, an average of one out of every ten vehicles on the road is driven by a legally drunk driver.

"A prepared amateur . . . can be of excellent service to the community if he or she does encounter a drunk driver."

I wanted to educate my club's members about how they, as hams, could help control the drunk-driving situation. Many amateurs don't know how to report a drunk driver, or they think it's much harder than it actually is, or they're in doubt when they see a hazardous driver. Perhaps they think it's not worth taking up a repeater to put in a call which most likely will be ignored anyway. I wanted to put these false suspicions to rest.

As it turns out, it's very easy to report a drunk driver. When in doubt, it *is* better to report the vehicle and have it checked out by the police. By not reporting it, you are allowing a possible highway catastrophe to happen. The highway patrol will take action if it receives a *well-defined, concrete, and legitimate report.* All it really takes is a ham with a hand-held or mobile radio to report a suspicious vehicle to a base station. The mobile operator then passes on to the base-station operator the suspicious vehicle's highway location, direction, approximate speed, make, color, year, and license-plate number (or as much of this information as is known). The base then passes this information to the local sheriff or highway patrol (whichever is appropriate for your area). A convincing way for a base-station operator to report an incident is to place the phone against the base radio speaker, so the officer hears the mobile operator report the incident firsthand. The base-station operator should then record all the information in his or her logbook or records.

Having spoken with the highway patrol office, I began speaking to other hams, giving them the facts and showing how it is possible

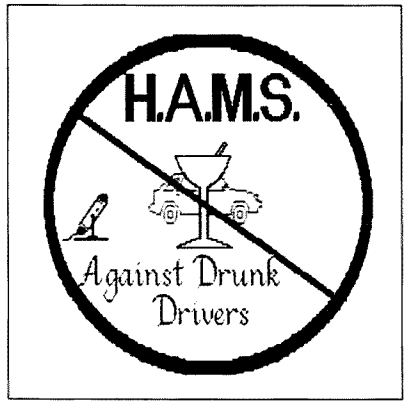

Fig. 1. The HAMS logo.

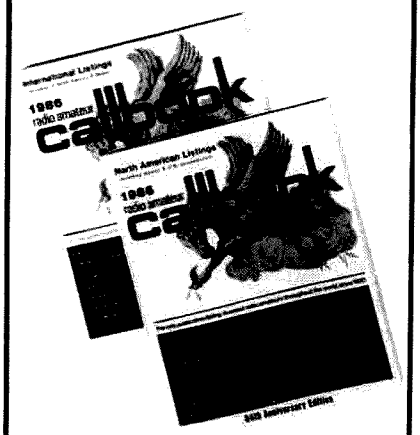
to help stop drunk drivers. I have also spread the word on the air, in our local Ham Radio Outlet, and in our San Fernando Valley Amateur Radio Club (W6SD) newsletter. Other club newsletters have printed my information about drunk drivers, as well. I also arranged for Officer Ken Rosenberg of the California Highway Patrol to speak to the San Fernando Valley ARC about the facts and procedures of reporting a drunk driver. The club members showed a willingness to support the program and are optimistic about their ability to make it work. I named the program the Highway Amateur Monitoring System, or HAMS as an acronym. Since then, there have been many incidents on the air in which hams have helped people on the road by making a report to the highway patrol.

The Highway Amateur Monitoring System is *not* intended to "scan the road for hazardous drivers." Rather, its function is to *prepare* an amateur to be able to deal with a road hazard if one should occur. Amateurs who have mobile gear must know how to perform an emergency communication, and they must know that the highway patrol is on their side and will respond to an emergency call. A trained amateur can report a disabled vehicle, an accident, a highway injury, or basically anything that poses a hazard to traffic or individuals on the highway. For example, on March 26, Ken Yaecker N6NHA called in on our local repeater and reported a stranded vehicle in the center divider lane of the freeway. The driver of the vehicle was too frightened to get out of the vehicle to call for help. But, because of Ken's radio call, a base station reported the information to the highway patrol, which then dispatched an officer to the site.

On another occasion, Hal Samuelson W6GXG drove by a vehicle that had pulled into the emergency lane. Inside, the driver lay back against the seat. While unsure about the condition of the driver, W6GXG reported the incident using his mobile radio. The highway patrol soon arrived and discovered that the driver of the vehicle had suffered a heart attack and was unconscious. Paramedics were then summoned to the site. This man could have died in his car had it not been for W6GXG's suspicion that something was wrong.

A prepared amateur can be of excellent service to the community if he or she does encounter a drunk driver. For example, at around 11:30 pm on Saturday, March 1, just five nights after Alex Vincent's death, a report came on our repeater about a recklessly driven tractor-trailer that was swerving and making S-maneuvers at about 70 miles per hour on the highway. The report came from an amateur with a mobile 2-meter radio who was traveling behind the tractor-trailer in the Gorman area, a dark, mountainous area north of Los Angeles. I answered his call and phoned the highway patrol, placing the phone against the speaker of my base radio so the officer heard the mobile ham directly relay the information about the vehicle. After the report was complete, a vehicle was dispatched. Twenty minutes later, the mobile ham reported that the highway patrol had stopped the still recklessly driven tractor-trailer and pulled it off the road. Had it not been for the ham-radio effort, the tractor-trailer could have killed somebody.

Alex Vincent—Victim of a drunk driver on February 24, 1986.



These incidents illustrate some of the ways in which the HAMS effort has been a success. Obviously, not every incident on the road will be witnessed by a ham, and nobody can force a ham to call in something he or she sees on the highway. But it is possible to educate the amateur community about drunk drivers and highway communications—as I have done in the San Fernando Valley.

The drunk driver suspected in Alex's death was brought under "suspicion of vehicular manslaughter." Witnesses who saw the drunk driver minutes *before* the crash took place were needed to testify as to how he was driving on the road. If a base-station operator logs the information received about a recklessly driven vehicle and if, a few minutes later, the vehicle causes a fatality or an injury, then the amateur operating the base station can use those records to provide evidence as to how the vehicle was being operated moments before the crash. It could help to get a conviction.

As I continue the HAMS effort, I strongly encourage all readers to do as I have done. Become involved and contact your local sheriff or highway patrol. Invite an official to talk to your radio club about the facts of drunk driving and how to report a drunk driver. Any time that a ham reports a drunk driver, he or she is potentially saving someone's life. We hams have a great capability to talk to each other with our hand-helds, mobile radios, and repeaters. Isn't it worth taking up three minutes of air time to use these capabilities to help prevent a possible catastrophe?

Drunk drivers cannot be completely eliminated. But, with your help, we can reduce the hazards on our highways and prevent tragic deaths—such as that of Alexandra Vincent, whose goal was "to do something special" for everyone she met. ■

1986 CALLBOOKS

The "Flying Horse" has a great new look!

It's the biggest change in Callbook history! Now there are 3 new Callbooks for 1986.

The North American Callbook lists the amateurs in all countries in North America plus those in Hawaii and the U.S. possessions.

The International Callbook lists the calls, names, and address information for licensed amateurs in all countries outside North America. Coverage includes Europe, Asia, Africa, South America, and the Pacific area (exclusive of Hawaii and the U.S. possessions).

The Callbook Supplement is a whole new idea in Callbook updates. Published June 1, 1986, this Supplement will include all the activity for both the North American and International Callbooks for the preceding 6 months.

Publication date for the 1986 Callbooks is December 1, 1985. See your dealer or order now directly from the publisher.

□ North American Callbook	
incl. shipping within USA	$25.00
incl. shipping to foreign countries	27.60
□ International Callbook	
incl. shipping within USA	$24.00
incl. shipping to foreign countries	26.60
□ Callbook Supplement, published June 1st	
incl. shipping within USA	$13.00
incl. shipping to foreign countries	14.00

The Piggy-Bank Patch

Pete Putman completes the picture with an autopatch for his Piggy-Bank Repeater.

Many of the readers who contacted me after the publication of my simple repeater-control project ("Piggy-Bank Repeater Project," *73*, June, 1984) expressed interest in a companion autopatch controller, but at a budget price. The good news is that your wait is over!

This article describes a simple DTMF touchtone™ controller that uses inexpensive but reliable parts. Most parts can be obtained from the nearest Radio Shack store; the balance you can get from mail-order semiconductor houses. The circuit is relatively foolproof and offers secure, five-digit access and single-digit dump. Provisions have been made for muting the transmitted access tones, and the entire circuit interfaces with the Piggy Bank controller to provide dependable timeouts and disconnects, if needed.

The heart of the circuit is Silicon System's SSI 202 chip, which is a complete DTMF decoder with band-splitting filters built in. All you need to make it work are a 1-megohm resistor, a 0.01-uF input-coupling capacitor, and a standard colorburst crystal (3.579545 MHz)—all of which are easily obtained.

Your repeater's new autopatch: inexpensive, foolproof, reliable, and secure.

The SSI 202 runs from a supply voltage of 5 volts, and its output is either configured as 4-bit hexidecimal code, or binary 2 of 8. In this particular circuit, the hexidecimal code is used to drive a CD4514BE 4-to-16-line decoder, providing the necessary decoded digits. The SSI 202 has proven itself to be a reliable performer and exhibits excellent speech immunity. In fact, when the prototype was fabricated, I deliberately overdrove the input stage to see if the distorted audio products would create harmonics which would somehow "decode" as a valid digit. They did not!

Here's the interesting part: LSI Computer Systems of Melville, New York, has long offered a keyless-lock IC, type LS7220, to be used in automotive ignition lock systems. This chip is both inexpensive and flexible and lends itself well to a secure autopatch access system. In order to do its job, the LS7220 must detect five valid logic 1 signals in order at its inputs.

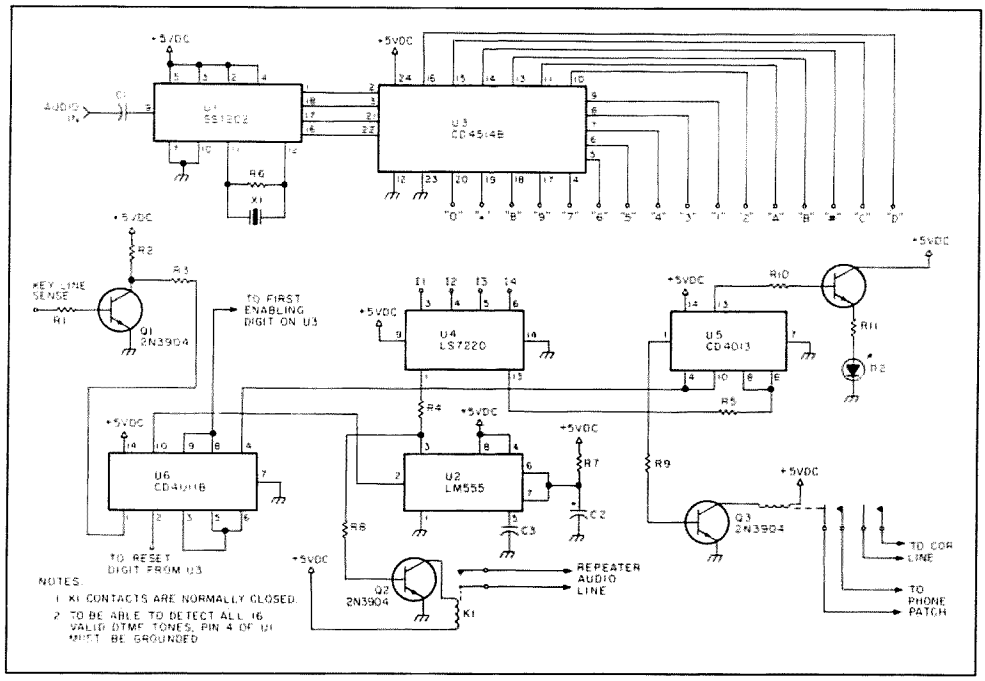

Fig. 1. Schematic diagram.

The first logic 1 is applied to SENSE INPUT to enable the chip to detect the remaining four signals. These are all momentary states and must be applied in the correct sequence. If any logic 1 signal is applied out of sequence, the entire chip resets to a zero state including all previously-detected valid inputs.

Example: Assume the access code is 51432. As you input 5, 1, and 4, you've set the SENSE INPUT and unlocked two of the four inputs in order. However, should you input anything other than a 3 for the next digit, the entire sequence must be repeated as all pins are reset to zero.

Once the correct sequence is accessed, the output pin, called LOCK CONTROL OUTPUT goes high and can be used to control a small relay. It also works well as a relay driver for high-current applications. This output will stay high as long as one of two things happens: (1) the SENSE INPUT is held high, or (2) a logic 1 is applied to the SAVE INPUT. For our purposes, we'll use option #1.

Refer to Fig. 1 for the schematic. Incoming line-level audio is fed through C1 to pin 9 of U1, SSI 202. R1 and X1 form the reference oscillator across pins 11 and 12. Valid digits are detected and appear as a hexidecimal code at pins 1, 18, 17, and 16. These in turn are connected to pins 2, 3, 21, and 22 of U3, a CD4514 4-to-16-line decoder. All 16 DTMF digits appear as a momentary logic 1 at pins 4–11 and 13–20 of U3, depending on the digit entered.

Let's say the first digit of the access code is 5. When a valid 5 is detected by U1, pin 6 of U3 goes high momentarily. This pin is inverted by U6C, a CD4011 quad NAND gate through pins 8 and 9 (which are tied together). Pin 10 goes low momentarily, which triggers U2, an LM555 one-shot. The output of U2 goes to two places: First, it drives Q2, a 2N3904 relay driver. This relay momentarily interrupts repeater audio and mutes the DTMF tones from being repeated over the air. The muting interval is also the window in which the remaining four digits must be correctly entered. This interval is set by R2 and C2 and is typically 1.5–2 seconds.

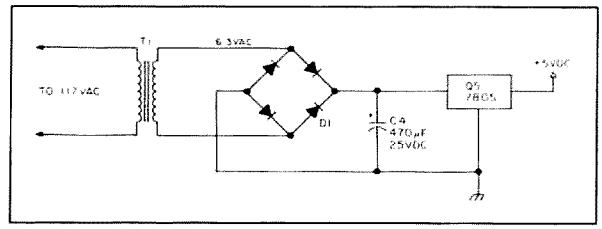

Fig. 2. Power supply for the autopatch.

The output of U2 is also sent to pin 1 of U4, an LS7220. This is the SENSE INPUT pin and must be tied high for the rest of the digits to be decoded. All of this takes microseconds to occur, so the dialing sequence can be fairly rapid—such as that initiated by an autodialing microphone.

Now that the tones are muted and the keyless-lock chip is enabled, the next four digits, 1432, sequentially decode the LS7220, and pin 13, LOCK CONTROL OUTPUT, will go high. The only problem is that once the window closes as U2 resets, the SENSE input will go low and U4 will reset.

Here's where U5A comes in. U5 is a dual D flip-flop. U5A actually controls the autopatch and COR LOCK relays—not U4. When U4 is set high at pin 13, this voltage goes to pin 6 of U5A. This is the SET line for the flip-flop. However, pin 4 must be tied low in order for the flip-flop to be set.

This is accomplished in a rather unique and clever manner! Q1, another 2N3904, senses the transmitter key line from the repeater controller. This line must go high on transmit. When someone keys up the repeater to dial up the patch, the transmit key line goes high and Q1 inverts this signal. It is then fed to pin 1 of U6A, another NAND gate. Pin 2 is normally low (we'll get back to that) so the output of the gate—pin 3—goes high. This signal is inverted again and debounced through U6B. The output of pin 4 is now low while the transmitter is keyed up and this goes to pin 4 of U5A, the RESET line! Follow me so far?

After the correct sequence has been dialed, the SET line (pin 6 of U5A) goes high and the Q output of U5A (pin 1) also goes high. This drives Q3, yet another 2N3904, which pulls in R2. This relay actually turns on the autopatch, but also it is connected to your repeater's COR line and either grounds it or ties it high, depending on what's needed to make the repeater stay keyed.

Now the input signal can be dropped since the autopatch will hold the repeater on, and while it is on the transmit key line keeps the autopatch operative. The two circuits actually hold each other up! While this is all happening the repeater timeout timer is running (one hopes) and will play an important role which will be covered in a moment.

Let's go back now to pin 2 of U6A. This pin

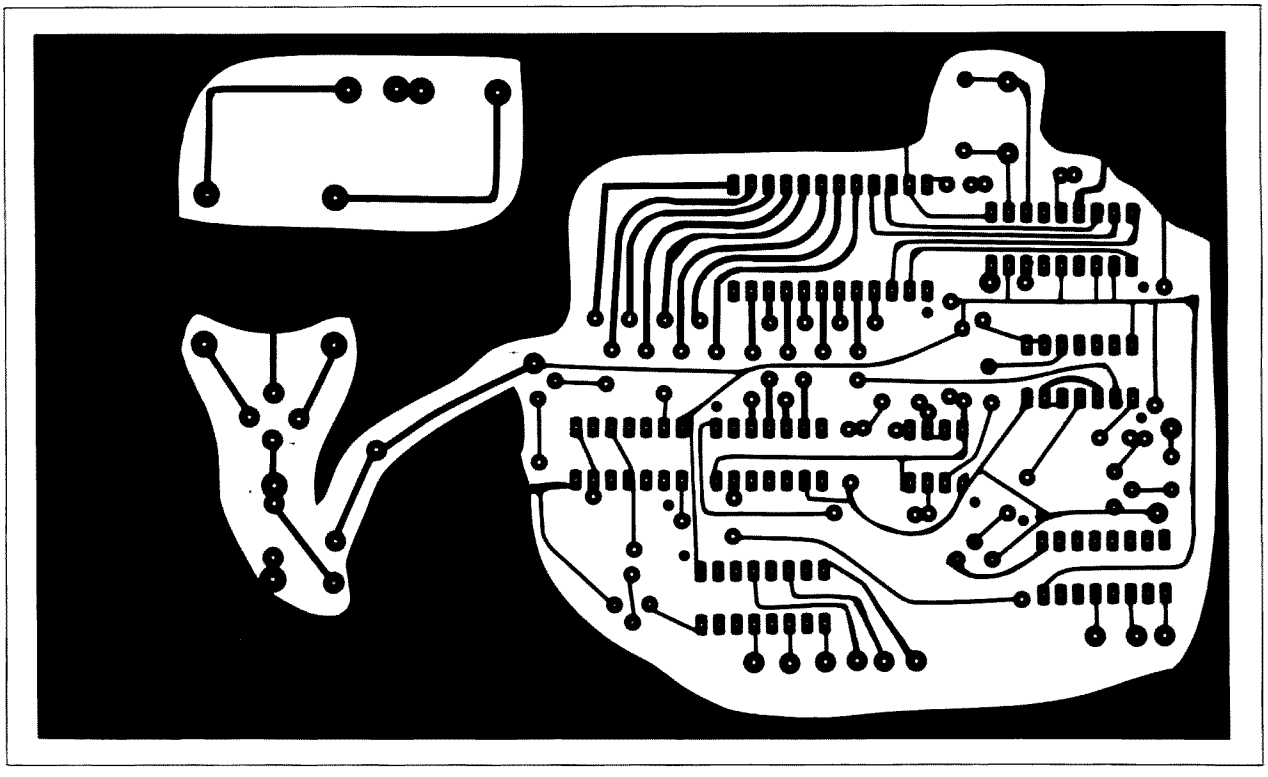

Fig. 3. Circuit board, foil side.

is normally low since it is connected to one of the pins on U3 not normally in use. We'll assume that pin is the # symbol. Should U1 detect a valid # (as it would when you decided to disconnect) and pass it along to U3, pin 14 of U3 would go high momentarily. This also would drive pin 2 of U6A high, thus causing pin 3 to go low. This would invert through U6B, which would then drive pin 4 of U5A high, thereby shutting off the autopatch and releasing the COR line. Clever, eh?

Now let's assume that in the middle of your call your batteries go dead. Horrors! You can't shut the patch off and there isn't a spare battery in sight. Not to worry, for the repeater timeout timer will run its course and shut the transmitter off. The minute this happens, the key line sensed through Q1 will go low. The signal is inverted, and this time pin 1 of U6A is tied low—not pin 2. The effect is the same, however. The RESET line of U5A will go high and *clunk*, off goes the autopatch. This is what makes the system foolproof—assuming the timeout timer works okay. If it doesn't, you'd be off the air anyhow as this is an FCC requirement for repeaters.

The other half of U5 is put to use to drive a small LED through Q4 to indicate that the system is up. Also, should you desire to inhibit the patch for any reason, put a switch with the key-line-sensing transistor, Q1, and your transmitter will keep pin 4 of U5A tied high when it is shut off. No matter what you do, you can't bring up the patch as long as pin 4 is tied high.

Incidentally, you can drive your COR line directly from pin 13 of U5B if you don't need the LED indicator. Pin 13 goes high when the patch is on, and can hold a COR open through a 10k resistor. For low-going COR circuits, use pin 12 of U5B through a 10k resistor.

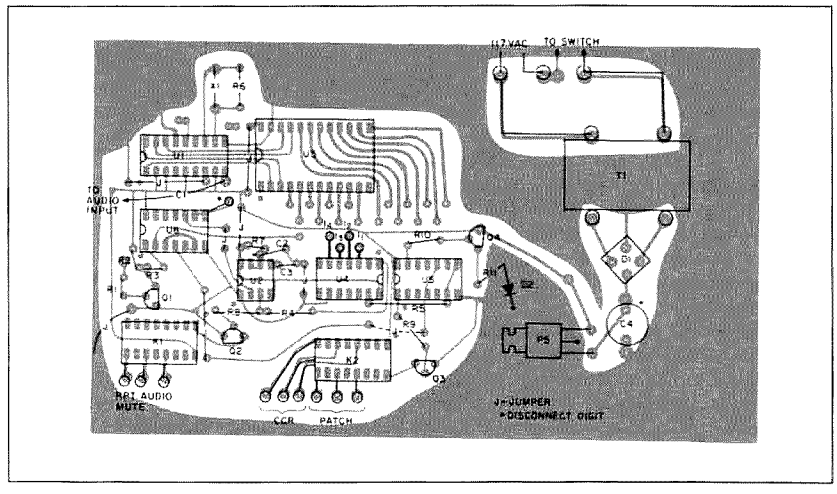

Fig. 4. Parts placement diagram.

The power supply is simple indeed (Fig. 2). T1 is a 6.3-V-ac, 300-mA transformer. Rectifier D1 is a full-wave bridge which feeds C4 and Q5, a 5-volt regulator. The entire board measures only 6-3/4" x 4" and fits in a standard enclosure. The photo shows the assembled unit. Fig. 3 is a full-size template for the PC board, and Fig. 4 shows parts placement.

The actual patch circuit is up to you. The old Heathkit™ makes an excellent choice, and there are other models floating around the market which will do the job nicely. You could even fabricate something yourself, if need be.

Here's the best part: All of the parts with the exception of U1, U3, and U4 can be bought right down at your local Radio Shack store. U1, the SSI 202, may be bought from Hallmark Electronics (See below for address).

U3, the CD4514, is available from Jameco Electronics, but since they require a minimum order of $20.00, you might wish to get most of the parts there as well. Otherwise, the

Sources for the SSI 202 chip:

Engineering Consulting*
583 Candlewood Street
Brea CA 92621

Hallmark Electronics**
107 Fairfield Road
Fairfield NJ 07006

*—This company advertised a complete kit for $22.95 for the SSI 201, the predecessor to the SSI 202. The chips are NOT compatible, but they may now be selling SSI 202 kits. It's worth an inquiry.

**—Hallmark does stock the SSI 202 and the cost per unit, as of this writing, in small quantities was $25.00 apiece. Write for ordering information.

Future Hams of America

CMARC shared the excitement of ham radio with 8000 visitors to the Boston Museum of Science.

Bob Salow WA1IDA's dreams came true when the Council of Eastern Massachusetts Amateur Radio Clubs, CMARC, an ARRL organization, dominated Boston's Museum of Science on April 26–27 for an extraordinary exhibition of amateur radio. Salow, the primary driving force, had devised and nurtured the plan for over a year before its fruition.

Why a science museum? Jim Fisk W1HL, President of the Billerica (Massachusetts) Amateur Radio Society, felt "a demonstration would not attract people to come to a museum." He believes that the main thing that attracts people to a museum in the first place is their natural curiosity. And he thinks it is *this* group of people that would be inclined to get involved in ham radio.

The museum identifies itself as "a world of ideas," with exhibits of natural history, physical science, medicine, and astronomy, but according to Salow, the one thing it lacks is electronics—specifically communication.

CMARC, with the support of the ARRL, saw the project as an unprecedented opportunity to promote interclub involvement of its 45 clubs. Salow recalled a similar event in 1977: "It was well attended. There seemed to be a lot of interest. My thought was [that] there should be some continuation of it."

April 26th was gray and cloudy—a perfect day to go to a museum. The exhibit, consisting of nine large curtained areas, occupied more than a third of the museum's lower level. Museum staff greeted visitors, passed out literature pertaining to amateur radio, and directed people to the various ham displays. In only two days, close to 8,000 people learned what amateur radio is all about.

One of the most popular attractions was code practice. Young and old alike received a 5-minute lesson and certificate of completion. Saturday's code instructor, Wayne Bethoney KA1NSE, said, "Everybody smiles when they get it right. Sending their name is the first big step. Women are very interested in joining. Kids and adults—the interest is mixed."

With certificate in hand, the FHA—future ham of America—rounded the corner to the next stop—to send a *real* message or to visit OSCAR.

One of the volunteers, Dana Tremblay

Photo A. One week before the exhibit opens: antenna assembly on the roof of the Museum of Science.

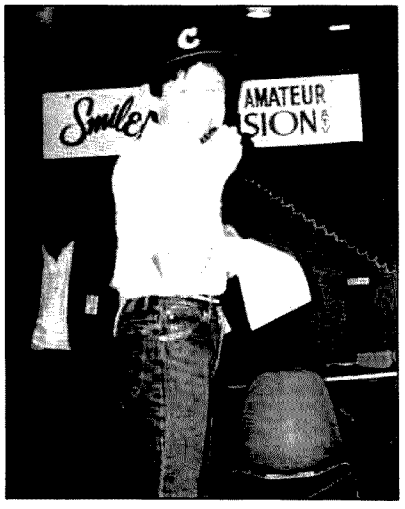

Photo B. "Look, Ma, I'm on TV."

WA1HUM, reported some technical difficulties: "It's probably one of the worst locations in the city you could have. The problem is interference." Part of the problem was overcome by ham ingenuity—a coffee-can configuration set up to act like a filter—and an AMSAT video showed what was supposed to be happening. Tremblay said, "People interested tend to be older, more sophisticated. The general reaction is 'Amateurs have a satellite up there?' They want to know how far away [it is], how much it costs, [and] how big it is—really."

Lines formed for the amateur TV display while giggling girls talked to a 15-year-old Wakefield, Massachusetts, ham. "Can he see us?" they asked. Bob Crowley, another CMARC volunteer, observed that both children and adults were fascinated by the video aspect of ham radio. "They want to know how to hook up the VCR they bought for Christmas. For kids who have been spoon-fed TV, it has immediacy." Other questions from the crowd, such as "Can you turn the channel and get someone else?" or "Who's filming this?" brought smiles to any ham within earshot.

Virginia Williams KA1KKS, who manned the message center, said, "They think it's fun to see the message sent. Mostly, they say, 'Ooooh, how can they do that?' We've had more messages from children than anyone else."

Packet radio, headed by Ron Reder KA1KCU, was another crowd pleaser. "Most people seem to enjoy it," he remarked. "They're very interested." But interest isn't always enough. "You have to go out and greet people," he continued. "Bring them into the booth. The approach has a lot to do with it, like [it did] to a second grader—her mom had to help her type."

The two-way HF communication setup brought in countries like Scotland and the Ukraine. Visitors were able to check various maps to see how far the signal was traveling. Gary Skuse KA1NJL, an enthusiastic worker, noted, "Little kids are awestruck. They think it's fantastic. They ask, 'Who are you talking to? How far out can you talk?' People seem very interested and want to get involved. It seems to be that children are more interested."

Pat Couture N1CKN directed the information station and was assisted by Libby Karpeij KA1DTU of the ARRL. Karpeij reflected on her involvement with the event: "I asked if I could observe. The whole thing was completely underway. I don't think it's been done on such a large scale. The more clubs that could do it, the better. But unless you have simply an enormous club, it's really not practical." According to Couture, the event was particularly significant because "this is the first time ham radio has gone into the public and interfaced on a large scale. Everybody is looking at this."

The ham spirit prevailed, as one Girl Scout leader commented, "I've never seen an exhibit as warm and friendly as this. People went out of their way to talk to [the girls] and draw people into the exhibits."

Photo C. A code class led by KA1NSE.

At the message center, Tom Kinahan N1CPE, a team leader, explained that "traffic originating at the museum was sent to remote station K1KTZ in Wellesley, Massachusetts, via packet links. At this station, all incoming messages were dumped to a printer and from here, they were routed via 2 meters, HF nets, and informal liasons to other destinations. All traffic was originated under the call KA1SM."

After it was over, museum staffer Phyllis Dohanian said, "It has worked out pretty well. The director would like to see something like this every weekend. I don't think it's a child's activity; you need motor skills and a level of intelligence. I tried to get Bob to focus on how things work—a key into science, to teach about any kind of radio transmission."

Salow's dream was to target the exhibition toward a preselected audience: "The objective, long term, is to get a permanent exhibit at the museum. I realize you can't put one in [with] *magic*. You have to get a degree of credibility, raise money, get equipment, and stock it."

No one knows exactly when the idea started, but fund raising for this event began long ago with the sale of a map showing 2-meter repeater locations in New England. The map was prepared with great care by Lew Nyman K1AZE. "The map sold very well," Salow said. "We sold ads to defray the cost. We printed it up and sold it for $2 at flea markets, hamfests, everywhere. The money enabled us to move on this."

The next step was to approach the museum. Salow tried to "find people with influence in the museum like Bradford Washburn, world famous and former director. We got names of people at the museum a year ago and waited. Nothing happened. We called them. It was very difficult to get in touch with them."

Phyllis Dohanian of the museum's Service League mentioned some obstacles CMARC encountered that any group would encounter in an undertaking of this nature: "[CMARC] wrote the former director. [The museum bureaucracy] had mixed feelings. [They thought it would be] an activity where people participating [would have] fun, but [wouldn't] interact with museum visitors."

But Salow persisted. His ambition and perseverance finally succeeded: "Last October we made contact."

Another problem surfaced. Dohanian explained: "We have a very busy schedule. The museum couldn't give me the time and personnel to do it. We are run nonprofit and have to do things the cheapest way. People don't get paid the same way."

Guidelines were established for the proj-

ect. "We looked at it again," Dohanian said. "We wanted it [to be] scientific, educational, [and] interactive with museum visitors. We got together, mostly Bob and me, and talked about quite a number of logistics, dealing with the physical plant, electronic equipment interacting with electronic equipment at the museum."

Next, Salow "sketched out the budget and all kinds of other things. It did not move quickly. In February, we got the answer—OK. We had to set a date, but they couldn't give us a confirmation. It was March before we knew what was going to happen. We got a date in April."

Dohanian praised Salow: "He had the best way, a number of group leaders. When they needed something, he and the group leader would meet with the appropriate person."

Salow recruited and recruited and recruited, because "no one club could put together an exhibit without the knowledgeable people. Most clubs are general-purpose clubs." A great many hams were at the Dayton Hamvention, and so were unable to lend a hand.

So now they had the museum. They had the people. But what about equipment?

Steve Gilbert WA1AYS, a CMARC volunteer, is a walking success story. "I contacted Dave K1WHS on 2 meters. He owns the Main Monster, a 2-meter moonbounce station, one of the biggest stations in the world. He passed the word to his boss, Glen White of Cushcraft. My question was to borrow an antenna. He asked, 'What else do you need?' "

Gilbert's fancy footwork procured loans from Carol Cable of Pawtucket, Rhode Island, for 1,000 feet of 9913-equivalent, and another 1,000 feet of actual Belden 9913 from Belden Cooper Industries. Gilbert added, "The companies were tremendously helpful. You have to give them credit for more than giving us the stuff, but for the vision."

The challenge of erecting antennas was met with great vigor. Each of the nine antennas for the exhibit required 150–180 feet of feedline. Originating on the roof, the feedline was fed down through three floors, in and out of doors and windows to the basement. The real challenge was getting a 6-foot ham with a 5-foot tower through the boiler room, around a corner not much wider than his shoulder, and up two flights of stairs. Antenna sections were passed along like a bucket brigade and handed up to the man at the top of the stairs. Prior to the exhibit two consecutive weekends were needed to assemble, transport, and erect the metal monsters that would loom over the museum.

On May 24, 1844, Samuel Morse transmitted the first message on U.S. telegraph. 142 years later, a short distance from his birthplace, hams of the future watched messages on television, printers, and screens. The exhibit succeeded in bridging a gap between today's youths and the world of amateur radio. It proved beyond a doubt that almost 300 CMARC hams are anything but amateur. Salow commented once that "when you deal with me, you deal with perfection," and anyone who visited the museum that weekend would say that he was absolutely right. ■

Inside Tips

1. If you plan to have an exhibit, first write the museum director, head of exhibits, or someone in charge of special programs at a science museum, industrial museum, or any adult museum.
2. Arrange a meeting to discuss the possibility of an exhibit. Determine if the museum is willing to sponsor or co-sponsor it.
3. Allow a minimum of six months lead time, but a year is better.
4. Pray for rain. Perfect weather means low attendance.

CLUBS

Marc Stern N1BLH
c/o 73

Publish or Perish

Does a great club mean a great newsletter, or is it the other way around? N1BLH, a man with ink in his veins, helps you resuscitate your rag.

One of the most important offices in any club is that of newsletter or bulletin editor. That task provides the glue that binds a club together during the month. Like completing a circuit, a club's monthly newsletter provides a path through which the news and notices flow.

Newsletters typically range from professionally typeset, printed, and bound publications to one-page sheets that are hastily run off at the corner copy shop. Unfortunately, there are far too many of the latter across the spectrum of radio clubs and far too few of the former.

Usually, the more professionally done newsletters are found in clubs that not only have an active membership, but that are also exciting. These clubs have a dynamism and energy that spreads from the youngest member to the oldest operator. Quite likely, these clubs also have active class programs that encourage new operators to enter the hobby, as well as active social, educational, and operating calendars to keep everyone interested.

This isn't to say those clubs with one- or two-page newsletters may not be equally active and exciting. What they probably lack is the funding to handle the printing, which can easily run over $1,000 per year for a 100-member club with 11 or 12 newsletters.

Fig. 1. Past Newsletter of the Month winners.

Still, it's unlikely that clubs that hastily print one-page, poorly typeset and reproduced newsletters are very active. Quite likely, the president not only heads the club but also writes the newsletter; takes the minutes; handles correspondence; finds speakers, films, or activities; as well as types up the mailing labels and licks the stamps. It's a one-man show that has fallen on his shoulders by default. All it takes is one volunteer, the editor, to begin changing this picture, and the newsletter is off the ground.

However, while volunteers can make a great deal of difference, another key ingredient to a successful newsletter is the willingness to fund the cost of production. Unless someone in your club owns a print shop or knows someone who does—an ideal situation—the chances are good that you'll find you have a monthly cash outlay, which a club can't be afraid to make. Since the newsletter is the most visible part of the club to many hams and community leaders—if they are included on the mailing list, which they should be because it's just good public relations—and since it is also the primary news medium for members and potential members of the club, it pays to do the best job your club can afford.

If, for example, you can afford professional printing but not photo work, then don't use photos. Retain the professional printing, however; it lends a finished look to the publication.

The most important ingredient after the editor and funding is support. Since the newsletter is the club's mouthpiece—not the editor's private soapbox or the executive board's private opinion sheet—the editor

must encourage club input. In many cases this is like pulling teeth from the proverbial chicken, but it still has to be done.

For example, in the club where I am newsletter editor—the Framingham (Massachusetts) Amateur Radio Association—I have encouraged members to submit whatever they want to submit, and I've had a fair degree of success. Recently, a couple of our women members asked if they could have some recipes published and I said, "Why not?" Yes, it did raise hackles, but it shows the type of latitude we try to allow in the newsletter.

At other times, I've had people come forward with long lists of DX operations and beacons and we've published those, too. In fact, there have been some months where I've had so much material, I've had to hold some until the next month.

I just wish that were the case all the time, but like most editors I've found that it isn't. Much of the time, I'll write just about everything in the newsletter except the minutes of last month's meeting, repeater notes, and a listing of local flea markets, exams, and special events. These are provided for me.

". . . the bottom line is knowing a job is done correctly and to the best of your ability."

And this brings us to another consideration: format. Before the final printing, it's a good idea to experiment with format on a dummy issue. If many of your club members are older operators, then it makes sense to use larger type so that it's easier for them to read. Likewise, it also makes sense to print text in page format rather than in columnar format, which can be somewhat harder for older operators to read.

On the other hand, if most of your members are on the younger side, then experiment. Try various type sizes and styles to give your newsletter a unique flavor.

For example, the newsletter of the Nashua (New Hampshire) Area Radio Club, which I see as part of our newsletter exchange, has a professional appearance. Not only is it printed in two-column format, but the type style is clean and readable. Also, the club includes photos, which gives its newsletter a professional feel. Besides, it's apparent from the photos that the membership is active and supports not only its club, but also its newsletter.

Another unique newsletter I have seen is that of the Wellesley (Massachusetts) Amateur Radio Society. WARS makes effective use of two-column format and graphic and shaded headlines to create a very pleasant newsletter. The writing is light and the typesetting good, setting this newsletter apart.

Looking at the other side of the coin, I have seen newsletters that are little more than mimeographed or photocopied one-page throwaways that do little more than announce the meeting and the meeting site. They aren't too informative and look so amateurish that you have to wonder about the quality of the club. The print quality is also usually poor because a wide-matrix dot-matrix computer printer has been used, making everything look shoddily prepared.

With the editor found, funding and support assured, and format determined, there's little more for the editor to do except put the newsletter together, right? The answer, unfortunately, is wrong because there's still more to do, as WA1UEH, our newsletter's former editor for seven years, can attest.

Even though we have seen it is possible to establish a moderately continuous flow of material, it requires an editor's vigilance to ensure that this material will keep on flowing. For the most part, a simple phone call gets it in on time.

This information-gathering process has been greatly enhanced by the arrival of the personal computer in the ham shack. Although I use mine for business purposes, I also use it in the hobby, as well as for correspondence. The same is true of other club members, several of whom also contribute material to the newsletter. We can do this because our machines are equipped with modems, which makes it easy for them to zip information to me. All they have to do is dial my home phone; the computer answers, and the information is transferred.

In this manner, we can update the newsletter until the last minute before it is transferred to the club president's—KB1EW—machine. He prints it out and has it printed for us. As

FILL 'ER UP

OK, so you've decided to really improve the old newsletter, and now comes the question of exactly what it is you're going to fill those brilliantly designed, professionally produced pages with. Somewhere in this world, there must be someone who enjoys reading the minutes of last month's meeting. We at *73* have never met the man.

People

As much as we like to talk about rigs, antennas, and the weather, the most interesting subject in ham radio is *people*. "Fred made a new antenna out of his old Nash Rambler. Bob tried to put up a dipole with a bow and arrow, hit a sea gull, and hasn't seen the antenna since. Crazy Larry fell off his tower again—he's got an HT in the hospital with him and he'd love to hear from you." The one thing people never get tired of reading about is themselves.

Activities

Your newsletter is your chance to light a fire under your club. An "active" club isn't one that just has regular meetings. Activate your club by selling the members on a pilgrimage to Dayton, or a barbeque in your backyard, or something. A newsletter that deals strictly in reporting what has happened in the past will be *boring*. Inject the future into your publication. "Field Day is going to be bigger than ever this year, that is, if you folks will just get going. We've had 27 people volunteer to help dispense the beer, but we could really use some help getting a Novice station set up." Production schedules and delays do have a way of turning your "future" writings into the history by the time the newsletter comes out, but at least you'll be closer than you were before.

Plagiarism

We at *73* do not care which of the other three ham magazines you plagiarize. But seriously, folks, if you see something in *73* that would be of use in your newsletter, write us a letter and tell us what you want to do. Chances are, unless you're trying to make a buck off the deal, we'll give you the OK. N1BLH tells you exactly where to look for the rest of your news—there's always lots of material; you just have to know where to look.

Art

Someone in your club has enough artistic skill to draw up a clever logo. Find him or her. It's true that you can't tell a book by its cover, but it's also true that your great information will be ignored if it looks ugly. Illustrations and cartoons break up the text and make for easier reading. Somebody in your club must think that he's funny enough to do a monthly cartoon. Give him a chance.

First Class

It takes only slightly more effort to put out a first-class publication than it does to put out a boring rag. The editor who has had the job dumped on him and who is given no help in the endeavor is unlikely to make the extra effort—he's also unlikely to be editor for very long. With a little help from *you*, your club's newsletter will be something people look forward to receiving each month. Without your help: "The June meeting was opened and the minutes of the May meeting were approved. Don Dirge brought up the subject of whether or not to move the club repeater, which is currently not working anyway because Bill Bore forgot to. . . ."

NEWSLETTER OF THE MONTH

Every month, *73*'s editorial staff sifts through the hundreds of newsletters that we receive, searching for one that stands out from the crowd. If you'd like to enter your club's publication in *73*'s Newsletter of the Month Contest, send it to *73* Magazine, WGE Center, Peterborough NH 03458, Attn. Newsletter of the Month.

you can see, there's very little paper that changes hands today, other than in the initial information-input process.

Even with this automation, there are months in which all the persuasion and reminding in the world doesn't produce much copy. In those months you must turn to your alternate sources of information—other club bulletins, ham radio newsletters, and organizations such as the Amateur Radio News Service.

From other club bulletins, you can usually extract local information about which club is doing what and where local classes and flea markets are being planned or held. Generally, you'll find that between your own input and local bulletins, you may be able to fill half the newsletter.

Your next source of information, then, comes from newsletters such as the *W5YI Report* and *ARRL Letter*. They provide up-to-date information on matters of crucial interest. In fact, many of the newsletters I see make liberal use of the information contained in these and other professionally produced newsletters. The only proviso in using this information is crediting the newsletter that originally contained it.

Likewise, the Amateur Radio News Service is an important source of input from across the country. Made up by several hundred bulletin editors, the *ARNS Bulletin* provides you with lighthearted material and cartoon fillers, as well as some serious editorials. You can use this information, provided you credit ARNS. ARNS is a separate group whose dues are $5 a year, but it's money well spent as I have found.

Finally, if you can do it—and if your budget allows it—try to use as many photos as you can. Not only does this create interest in the newsletter, but it also creates excitement in the club, which, after all, is the bottom line of any newsletter effort.

With all of this done, the mundane work is next: folding, labeling, and stamping. If you have several people on your committee, this can go quite quickly. However, most of the time you'll find that you're doing this yourself. Relax, though; it doesn't take too much time and, if the labels are computer generated, it will be little effort to label, stamp, and mail them. In fact, if no one in your club can generate computerized mailing labels, it might be a good idea for your club to invest in having several sets of labels printed. In the long run, it will save time and effort.

When all is said and done, though, the bottom line in the newsletter is satisfaction—the satisfaction that comes with knowing a job is done correctly and to the best of your ability. Don't think that as editor you'll find people rushing up to you month after month to pat you on the back for the fine job you're doing—because they won't. To the long-suffering editor, those comments seem few and far between. But don't think the club doesn't appreciate the job you are doing, either—because it does. It's just that when a newsletter is running well and arrives on time every month, people take it for granted.

In a way, though, having people take the newsletter and its quality for granted is the ultimate compliment. It means they're satisfied with the work you are doing and with the newsletter as a whole. In fact, this type of quiet is reassuring because, as editor, you soon realize that if you blow something, you'll hear about it loud and long. Now, isn't the quiet better? You bet it is, and it means your newsletter's a hit.

So, if you have the right formula, you've got it made. Your newsletter may never win national awards, but it serves its purpose and informs. What more can you ask?■

Genius Brings Home The Bacon

. . . and hogs the spotlight.

It has been nearly seven years now since the truncated success of my home-brew Mobius-twist, All-purpose, Synergistic, Lumped-constant circuit, Hanger-hung, Folded dipole, Phase-velocity, Transcalent-transceive System (MASLHFPTS™)—the Mark 1 version of which, you may remember, blew up Con Edison generators in New York City in 1965, extinguishing lights all along the East Coast. (That's what truncated the success, of course—for the first truncation, that is. Since I hadn't remembered to fuse the rig, it blew up, too.)

No, I will NOT apologize again! Hoo, boy! Some soreheads never forget the smallest inconveniences! And if Missouri hadn't run out of mules. . . well, that's what brought about the final truncation: not enough mules. Only a couple more years of mule-kicking of components into random configurations (see Fig. 1) and the single-sided-band MASLHFPTS™ circuit, whatever it was, could have been reconstructed. Then, not only would those power-outage complaints have been drowned out by roars of public acclaim for the new rig, but I'd have been a multimillionaire.

Anyway, it's been so many years that it is time once again to stimulate readers of *73* with news of another promising field for basic research, experimentation, and home-brewing. This time mules will not be required. The main reason I called for them before was to help out a friend of mine who ran a mule farm near Neosho, Missouri; he needed the new business. HE was the one who became a millionaire. He moved to Norway. "I'd always wanted to live in Norway," he wrote me, "but until your hundreds of hams bought all my mules, I couldn't afjord to." (He never could spell.)

As so often is the case with pure researchers—I mean, when one is engaged in pure research—I discovered this new field serendipitously as a by-product of my continuing efforts to discover how my Mobius-twist antenna and the Adjustment Circuit Box had brought in signals from Mars *in color* when the basic module of my rig was an old black & white TV set. (See "Einstein Was Wrong" in the October, 1979, issue of *73* if you want to see how all this got started.) I had used up my last mule and was reduced to doing my own kicking; I was just about to quit (my foot was really sore) when I was overwhelmed by that same courageous determination which in my teens had made it possible for me to locate WOR, WJZ, and so on, on the family wireless nearly every time I tried! I just had to make one more effort!

". . . I had a date with a gorgeous broad in Boston in a few days, a zoftig, blue-eyed blonde . . ."

I did so, waited for the solder to cool, plugged the new circuit into the Adjustment Circuit Box, and disappeared.

The Mark 1 PIGS

When I say I disappeared, I mean that that's the way it would have looked to you if you had been there watching me—I'm not suggesting any of that weirdo science fiction stuff that nobody but a congenital idiot would believe. I was still visible, for heaven's sake, I could still see myself perfectly well; all that had happened was that I wasn't in my QTH anymore! I was out in my antenna field, under a 70-foot tower that hadn't been there an hour before. An hour before I had seen it where the truck had delivered it, lying flat on the floor of my barn, in sections, ready for a tower-raising party scheduled for the next day!

It didn't take long for me to think this thing through and realize that something strange had happened. I mean, I have had lots of experiences and I know a strange experience when I see one. And I did what I had learned to do: I stood perfectly still and pondered the matter. Not necessarily in this order, these were my conclusions:

1) The strangeness was of a different order from those which hams all over the world had reported to me, resulting from their own mule-kick efforts to reconstruct the MASLHFPTS™. There was the XT in Africa who turned light blue all over (he became a very successful witch doctor; I get all my potions from him, now); there was the 4K1 who used his strange result to heat his QTH, but he couldn't turn it off, and his last transmission came from a depth of approximately 7,000 feet under the ice cap; and, of course, there was the VO1 whose circuit sent out a subsonic whistle. I'm not sure I believe him, but he was there and I wasn't. If he says that this whistle, being slower than sound, piled up around him like transparent whipped cream snaking out of a pressurized can, and that it pierced both eardrums before he realized what had happened and kicked the rig into silence, well, maybe. . . .

2) It wasn't a one-dimensioned strangeness as in those examples. In this case, both time and space seemed to have been involved, even if only modestly. The distance from my QTH to the now-erected tower wasn't much over 100 feet, and the loose, moist dirt near the tower guy anchors obviously was only hours old.

3) I couldn't stand there forever.

4) Maybe my MASLHFPTS™ was going to be an oxymoron! That is, maybe I was about to turn a failure into a successful failure of some kind. Could I have discovered (invented) a time machine?

Well, hoo, boy! It sure looked it!

All of that happened last summer. During the winter of 1985/86, I did all the tedious analysis the situation called for—disconnecting and reconnecting components, substituting different values of components, rearrang-

ing components, etc. I found early on that values had nothing to do with results. The 1000-Ohm trimpot did (or didn't do) exactly as much as a 1-Ohm job; 330 uF/30 V meant as much (or as little) to the whole circuit as 3 pF/30 mV. Even substituting a 2N2222 for an MPF102 produced only minor variations. What seemed to be the determining factor was the relative positioning of the 15 components which had hit the perfboard when I kicked the table (and, of course, which had encountered hot solder while in flight and had thus formed into a circuit).

This was fortunate indeed—a great time-saver! It takes only 12,440 millenia to try out all the permutations for 15 variables (testing one every five minutes).

Ah, you spotted something contradictory there right away, didn't you! Can't fool a ham! So you probably have figured out how I coped with the dilemma. Yup. I calibrated my time/space machine along the time continuum first, and as soon as that was under control, I merely went back to the year 12,438,015 B.C., planning to work right through to 1986 A.D.

There were some problems! Not with aging—my metabolism stayed in neutral all the time I was in either the past or the future—but it was pure luck that I survived that trip back to what I figured out later was the Miocene Age. No sooner did I ever settle down to work when some lousy volcano would errupt and I'd have to flee. Between volcanoes there were earthquakes, and all the time those pesky ramapithecines and sivapithecines (early orangutans) kibitzed around with me. Let me tell you, this planet was no place to be in the old days!

So, I simply sliced up the time span into 59,238 segments and visited 1776 America 59,238 times for 210 years at a crack. It was fascinating to watch the shaping up of the United States, and hoo, boy! are our history books full of lies! Abe Lincoln, for example...but that's another story. Anyway, that's how I completed the analysis job.

Oh, yes. The name of my time machine. You know about IGSs (inertial guidance systems); all the best submarines have them, for example. An IGS tells the man steering his submarine where he is. Well, it struck me (literally, as I'll explain below) that a POSITIVE inertial guidance system (PIGS) would be one which didn't just lay there, it DID something, so my pet name for the machine became Pigasus (you know, the flying hog). The full name under which I'll register the trademark is the scientific one, of course: Positive Inertial Guidance System In Synergistic Plasmoidal Advectionated Cosmic Energy (PIGSinSPACE). (There is a luminous glow around the machine when in transit.)

The name came from literally being struck since it was in my mind when I recovered consciousness following one of the earliest attempts to calibrate the machine along the space continuum. It seems that there is an interaction between the two dimensions: The time setting has to be adjusted in the context of the setting for the space to be traversed. The shorter the distance the more the time setting has to be reduced to compensate for some sort of warp.

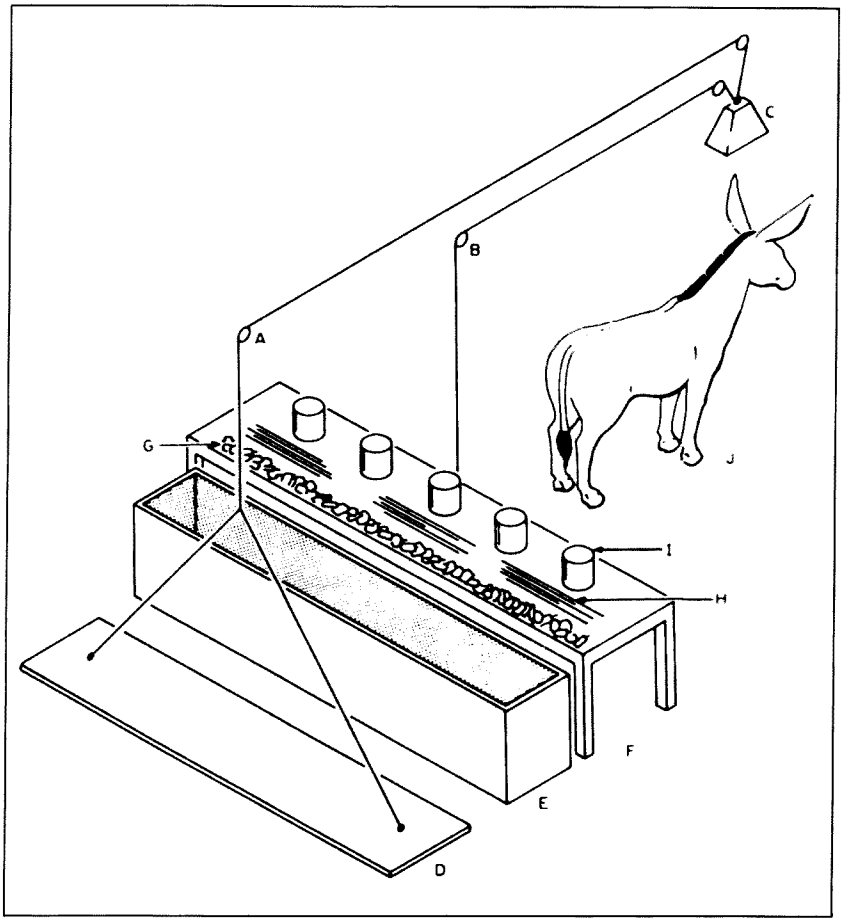

Fig. 1. Setup which might reproduce the original MASLHFPTS™. A—pulley system to jerk up cover (D) of Adjustment Circuit Box (E) when B, pulley system to weight (C) drops weight when mule (J) kicks over table (F) sending flying G—all components from your junk box, H—copper wires of assorted lengths, and I—pots of molten solder, into the perfboard-lined box and onto the cover as it flies up and over. Note: Weight C should be positioned to hit mule J on head to keep him calm until ready for the next setup. (Editor's Note: It has been estimated that 1000 of the world's most intelligent monkeys, working 16 hours a day at randomly "soldering" junk-box components together in order to duplicate either a MASLHFPTS™ or a PIGS, would make one heck of a mess and would smell like the stockyards of Chicago at the turn of the century.)

I had set the space control to take me to the office of a friend of mine in downtown Peterborough, and I set the time control for seven days in the past (when I knew he had been out of town—I wasn't ready to show him my machine). Well, his office is on the second floor of a building put up three years ago, and I arrived there four years ago and had one helluva fall through the branches of a pine tree, which knocked me silly. See what I mean?

Your Job, Should You Accept This Mission...

For reasons I'll share with you in a moment, I'm offering all of you readers who qualify a piece of the action (see box). It would be totally irresponsible either to market Pigasus in its present form (my Mark 1937945H model) or sell seats on it for trips to anytime. Not only should there be considerably more testing, but there are safety devices which need perfecting to avoid damage to riders at various stages. Cases in point:

1) An antigrav module to be plugged in whenever there is a likelihood that you could arrive in midair somewhen.

2) Drift prevention for the time and space settings. It is both physically and mentally painful to find yourself occupying two spaces at the same time even when they are only molecules apart—or worse, also at two points in time, even when separated only by nanoseconds. The sensation resembles that of being stretched on a Middle Ages torture rack between two high-fidelity speakers at full gain, both belting out "You're Nothin' But A Hound Dog," with one speaker equipped with a split-second time-delay circuit.

3) A governor is needed to prevent pur-

REQUIRED QUALIFICATIONS FOR DIRECTORS OF SWINE

1) Must be a citizen of at least two DXCC countries.
2) Must hold an Advanced ticket or equivalent.
3) Must be able to send 50 wpm in native language and 10 wpm in any ten other languages, at least one from each continent. (Drum proficiency may be substituted for an African language, smoke signaling for a North American language).
4) Must be able to modify an ICOM IC-27A to be an ICOM IC-751A using only parts from an ICOM IC-02AT, blindfolded, in a high wind, at 0 degrees C, wearing only mittens and sneakers.
5) Must have an IQ below 75 or above 150. Individuals on those levels have much the same mental characteristics. (Actually, this qualification may be assumed to be possessed by any ham who applies for a directorship.)

chasers (or renters) from visiting the future, unless they are cleared to do so by the appropriate federal agencies (FBI, CIA, FCC, FDA, NRA, LSD, etc.) and religious institutions (Council of Churches, the Vatican, and their Judaic, Moslem, Hindu, Buddhist, Druid, and etc. counterparts).

It is this last point that is of significance now: I am offering you a place on the Board of Directors of the Foundation for Synchronizing Waveforms In New Energies (SWINE), a nonprofit organization to oversee use of Pigasus, because I won't be around much longer to handle that task personally. You see, I visited the future once too often myself.

Mind you, I didn't mean to; I'm too smart for that. It was simply another case of learning by experimenting, and as we all know, sometimes we learn things that do us no good at all. Like those two innocents and the apple.

In my case, I had a date with a gorgeous broad in Boston in a few days, a zoftig, blue-eyed blonde, and the more I thought about it the more I just couldn't wait to find out if she and I had a future together, so I set my time and space controls for August of 1989 at her pad, threw the KPDT switch, felt the typical sleepy sensation, smelled the usual attar of roses (some sort of overheating of the special polytetrafluoroethylene insulation I developed, I think), and ttwweeeeeYUP, there I was in her living room and there she was: lying face down on her sofa, one arm under her head, the other draped over the edge, her hand gripping a newspaper. She was weeping. Great sobs were alternated with deep gulps of air....

Clearly there had been something in the paper—and I tiptoed over, craned my neck, and was able to read black headlines: a three-column spread on the right-hand side, and a subhead:

N.H. MAN DIES HEROICALLY

SAVING CHILD IN CHARLES RIVER

President Dianne Ritson

Establishes Federal Holiday

in Memory of Richard Phenix

I Pigasused back to Peterborough. I dunno. Maybe I should have checked the date on the paper...maybe I had been clumsy making the time setting...maybe it had been 1999 or something. I mean, Dianne is still Art Director for *73*, and so far nobody has even guessed that she has political ambitions....

Well, I found out that my zoftig, blue-eyed blonde and I did have *something* of a future (another damn oxymoron: another truncation: a futureless future). I mean, I was being cried over, wasn't I? Something must have transpired that she thought she was going to miss...unless my money.... No. Couldn't be that. I have only a couple of million in the bank.

Anyway, that's why NOW is the time for all you hams out there to apply for seats on the Board of Directors. ■

AIRDISK

AND AIR-ROM CARTRIDGE
For both the COMMODORE 64 and VIC 20
(Soon for the new C-128)

Works with all these fine terminal units to bring you the ultimate in RTTY/CW/AMTOR performance. New AMTOR + program with variable PTT delay for slower rigs and high rate bit sync to compensate for computer clock crystal variations. It's the best $39.95 you'll ever spend to improve your station. Don't have a disk drive, then use the ROM cartridge at $59.95. On performance and features vs. cost, nothing even comes close! No complicated menus to bog you down. No limited performance programs here. The AIRDISK will enhance **any** demodulator. Disk works with both computers. Specify which for cartridge.

HERE ARE A FEW OF ITS MANY FEATURES:

• on screen tuning indicators • full or split-screen • auto-load memories* • output to commodore printers • full speed operation, morse to 99 wpm. Baudot to 132 wpm, ASCII to 300 Baud • 4 mode AMTOR • WRU • independent RX/TX normal/invert • pitch reference CW tuning • real-time disk communication* • break buffer • random code generator • RX/TX of basic programs* • 24 hr. clock • unshift or space • foxtest and more.

Administering the Novice Exam

Put back some of the pleasure you've taken from amateur radio—bring a Novice into the fold.

It is always nice to return something to the fraternity of ham radio, either because we like to help or because of a desire to repay the help someone unselfishly gave us. Many hams participate in emergency services, public-service communications, and the National Traffic System. Others hold ARRL district offices, are members or elected officers of local ham clubs, serve as volunteer examiners (VEs), or are Novice/upgrade instructors.

With so much to do in ham radio, one of the finer pleasures, I believe, is the training, testing, and licensing of new hams. Getting someone started on the road to the high adventure of ham radio is a rewarding experience for those who take the time to participate.

With the advent of the recent VE program, ham licensing is easier and quite a bit more convenient than it ever was. Not changed, however, is the Novice licensing program.

To get up on the first rung of ham radio, the candidate must acquire these minimum skills: sending and receiving Morse code at a speed of 5 words per minute, and the lowest level of knowledge pertaining to FCC rules, safety, simple operating procedures, and basic electrical principles. Before the ham aspirant can get on the air, that minimum amount of knowledge must be demonstrated in a test.

The written portion of the Novice exam is very plainly laid out in the widely available American Radio Relay League publication, "Tune In The World With Ham Radio" (complete with 5-wpm code tape, $10, ARRL Headquarters, Newington CT 06111). The questions and answers from the Novice examination pool are in the publication and can be mastered in a few evenings of reading. Separate copies of the question pool can be obtained from either any FCC Field Office or the ARRL at no cost.

Code practice is accomplished by listening to the accompanying ARRL tape or through the purchase of other tapes available through the advertising pages of the various ham magazines such as *73*, *QST*, or *CQ*. When the Novice candidate is ready for testing, he or she must find a General-class (or above) licensed amateur who will prepare and administer the Novice test. The candidate must have an FCC Form 610 (June 1984) or the examiner may request one from either the ARRL or the FCC (PO Box 1020, Gettysburg PA 17325). Candidates usually do not have or know how to obtain Form 610, so help may be needed.

" 'How'd you do on the code test?' I asked. 'What test?' the candidate asked. 'The one you just took!' "

In addition to being General class or above, test administrators must be 18 years of age or older, must not be related to the candidate, and must not have an interest in the manufacture or distribution of ham equipment. These restrictions mean that you cannot give the Novice exam to your wife or to a family member—a handicap, but a necessary one to prevent nepotism.

So, as a qualified Novice examiner, how does one give the test? It is quite simple. Utilize the Element 1A pool of 200 questions. This may be provided by the candidate or you may obtain your own. Ask for "PR Bulletin 1035-A."

The question pool has been subdivided into 20 blocks of 10 questions each. The applicant must answer one question from each of the blocks. The selection of the questions is up to the examiner. A passing grade is the correct answering of 15 or more questions.

The examiner may use any method of administering the test—including single answer, multiple choice, or essay type. He may conduct the test on an oral-interview basis or with a written form with a fill-in-the-blank or true/false format of his own construction.

The code test is administered prior to giving the written test. The examiner must determine that the candidate can receive code at the speed of 5 words per minute. This can be done by any method, usually by tape or key. The code may be sent for 5 minutes. I usually send plain conversational messages in the old format of name, callsign, QTH, RST, and weather report—as is normally encountered in the traditional opening lines of an initial contact. It doesn't matter what you send as long as the candidate can copy you.

Following the 5 minutes of sending, the examiner can ask 10 questions pertaining to the code text. The candidate must answer 7 of the 10 correctly to pass. As an alternative method, the examiner may ask for one minute of solid copy of a 5-minute string of random groups of characters. This means that the candidate must have at least five correct words in a row copied without error.

We must be fair to the candidate and

ourselves. There is nothing to be gained by passing a candidate if he really cannot copy code. We would be doing both the prospective ham and the ham community a great disservice. What we are really trying to determine is whether or not the candidate is ready to get on the air in the proper manner. That is what licensing is all about.

I have given many code tests. Usually, I send code at a speed measured by looking at the second hand on my wristwatch. It may not be a highly accurate method but it should be close enough. I usually manage to squeeze five words of five-letter length in one minute. Over a period of five minutes, any inequities should balance out. In most cases, five words per minute is easily judged by most General-class license holders.

I make up my own QSOs and follow by allowing the candidate all the time he needs to make sense of the text he has copied. Then I present the ten standard questions: "Who were you talking to? What age? What callsign? etc." The method seems to be fair, and if the candidate can honestly copy code he should have no trouble passing.

The last time I administered the Novice code test I deviated from my standard practice. As thousands of hams have done in the past, I gave the test in my ham shack at home. The candidate arrived, carrying his own newly acquired transceiver. He asked if we could set it up and try it out. Yes, that would be fun. Together, we hooked it into my antenna and swr meter, then went through the tuning procedure. I was a bit surprised to see the swr nearly top the scale. Had we forgotten an important step in the tuning procedure? We repeated the steps. Still the swr was alarmingly high. Was it the candidate's new rig? Then the embarrassing moment arrived when I discovered that my antenna switch was turned to the wrong antenna!

The candidate had a fine new hand key that he had mounted on a heavy brass mount. We plugged the key in and I sent out a few V's, then a QRL followed by CQ on low power. Nothing. Then, a few kHz up the band, I answered a rather erratic CQ at about 8 to 9 wpm. I returned the call, and my 10 Watts of power was picked up by a Novice about 150 miles away.

I threw a pencil to the unwary candidate and told him to copy for me. I sent QRS and cut my speed to 5 wpm. The operator at the other end didn't understand my request so I repeated it in plain text: "Pse slow down, I am very nervous." The operator came back at a slightly slower speed, but still very erratic and with many errors. Back again I went, "Please slow down, I have a Novice candidate here in the shack and he is trying to copy you." This was followed by my QTH, name, etc. The other operator came back with his information. I watched as the candidate unknowingly took his code test.

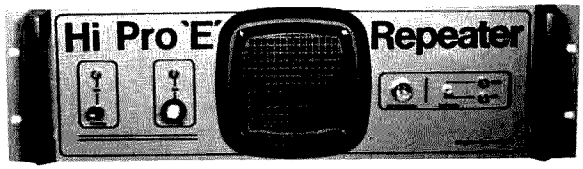
When we signed and sent our 73, I secured the rig.

"How'd you do on the code test?" I asked.

"What test?" the candidate asked.

"The one you just took!" I looked at the piece of paper he had copied the entire QSO on. It was all there, complete with mistakes! The other operator sent his share of L's for F's, G's for W's, and other common beginners' errors. It was his third time on the air! An on-the-air communication had taken place. It wasn't perfect. There were even QRM and QRN to put up with.

I asked the standard 10 questions. Who? Where? RST? WX? Callsign? It was good copy—not solid copy, but good enough to get the information needed.



The questions I selected at random from the question pool were answered 100% correctly. It was a painless examination for both the candidate and the examiner. We filled out the Form 610 together, carefully and block by block. I didn't want the form to be rejected due to some minor error or oversight. It has not happened to me in the past, but it would be very disappointing for the candidate.

With the 610 safely filled out and signed, I dropped it in the mail the following morning. If all goes well with the U.S. Postal Service and the FCC issuing office, the license should come back within 30 to 40 days. Then we can welcome a new Novice into the fraternity. ■

Troubleshooting With the DMM

A short course on checking diodes and transistors, complete with pictures.

The pocket digital multimeter (DMM) is the ideal test instrument with which to locate a defective transistor or diode in your favorite project, receiver, or consumer electronic equipment. A suspected diode or transistor can be tested within seconds—whether in or out of the circuit —with the diode test. Most DMMs have a diode-transistor test on the function-selector switch marked with a diode symbol. A DMM can be purchased for as little as $39.95.

Besides transistor and diode tests, accurate voltage and resistance measurements can be made. Very low voltage or resistance measurements are required in solid-state equipment. Accurate forward-bias readings of an NPN or PNP transistor are made easily with a DMM, and low collector or emitter voltage measurements can quickly identify a leaky or open transistor.

DMM Operation

Although a few digital multimeters have a regular transistor test, most meters have a diode test which can be used to check the voltage drop at any junction of a transistor. A diode can be checked for open or leaky conditions, while transistor tests can identify open or leaky conditions from any two elements of the transistor. A junction passes the test with a low reading in one direction and a very high reading or an over-range display in the other direction. The diode-test function can check

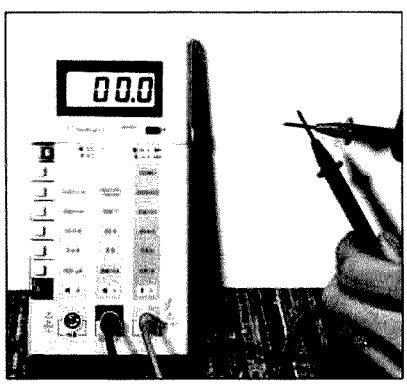

Photo A. Short the test probes together to zero the display before attempting to test the suspected diode or transistor.

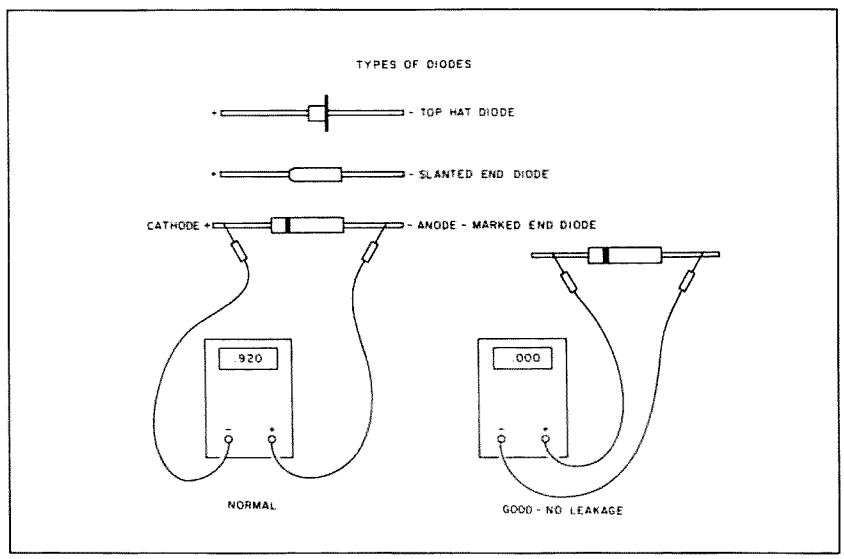

Fig. 1. A normal diode will display a value with the positive lead at the anode and the negative probe at the cathode.

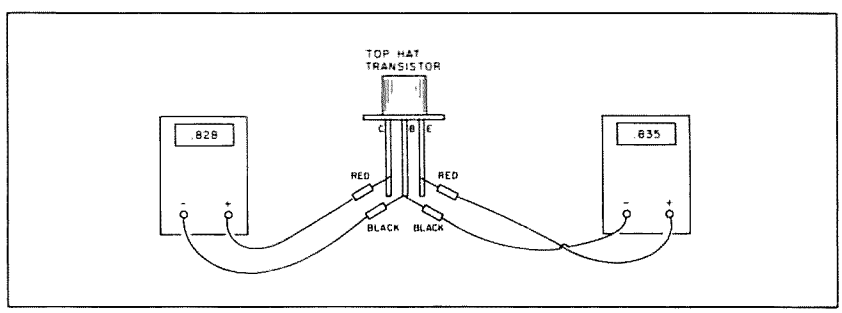

Fig. 2. The PNP transistor is tested in the same manner as is shown in Photo E, except that the negative probe is left on the base terminal.

semiconductor junctions in both diodes and transistors.

Practically every pocket DMM has a liquid-crystal display (LCD) that can be seen under strong lights. These displays are battery operated and have low current consumption. In some models, a weak-battery indicator will appear on the left side of the display. The DMM can operate from 3 to 9 volts for 150–200 hours of continuous use, making the small digital multimeter ideal for even big servicing jobs.

The voltage input range is from 0 to 2,000 volts dc and up to 1,000 volts ac. A fraction of 1 volt can be checked with .5% accuracy.

The resistance range can vary from 0 to 20 megohms with 1% accuracy. The 0–200-Ohm range will quickly check the .47-Ohm resistors found in audio-output transistor circuits. The current range can vary from 200 uA to 10 A with 1.2% accuracy.

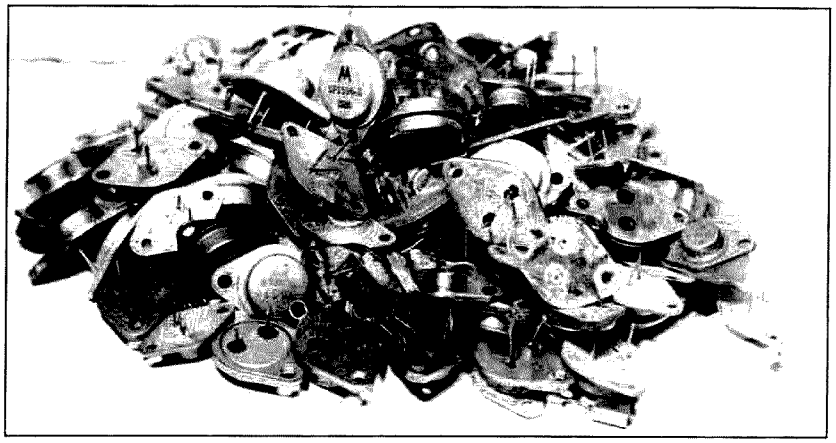

Photo B. Transistors come in many sizes and shapes. Here is a pile of defective transistors taken from a TV, radio, tape player, car radio, and various audio units.

How to Test a Diode

The suspected diode can be checked rapidly in or out of the circuit. With an in-circuit test, make sure a transistor, low-value resistor, transformer, or coil winding does not parallel the diode to be tested. If a transistor or resistor is found across the diode's path, a low reading may be found in both directions, indicating that the diode is leaky and is producing an incorrect measurement. When in doubt, remove one end of the diode from the circuit.

Rotate the DMM function switch to the diode-test position. You may find a push-button or rotary-function switch to engage the diode test. Check the zero of the meter by shorting the two test prods together (Photo A).

To test the diode, place the positive (or red) test probe to the anode terminal and the negative (or black) test lead to the cathode (see Fig. 1). The meter should produce a voltage-drop display on the LCD with a normal diode. Now, reverse the test leads. If the over-range display comes on, the diode is good. A normal diode junction will indicate a voltage drop in only one direction.

A leaky diode will indicate a low measurement in *both* directions. This indicates that current flow is occurring in both directions. A leaky diode usually has a resistance from 1k to 2k Ohms.

When the measurement is doubtful or a normal reading is not obtained, remove one end of the diode from the circuit. Now take another diode check. If high leakage is suspected, rotate the meter function to the 20k-Ohm range. With a normal diode, you should have a low-resistance measurement in one direction and very high resistance with the test leads reversed.

All fixed diodes, including zeners, can be checked with the above tests. Some damper diodes found in TV horizontal circuits can be checked like any fixed diode, while the old boost diode may not indicate a measurement in any direction. High-voltage stacks made up of layers and layers of seleninum diodes cannot be tested on the normal range of the DMM unless the diode is leaky.

Testing Transistors with the DMM

Transistors come in many sizes and shapes (Photo B). It does not matter what size or shape the transistor is; each can be checked with the diode and transistor test of the DMM. Most transistors in a defective radio can be checked in the circuit within a few minutes. Simply switch the meter to the diode or transistor function and place the probes on two transistor elements.

Place the positive lead of the DMM on the base terminal and the negative lead on the collector terminal of an NPN transistor (Photo D). You should have a resistance reading. Now place the negative probe to the emitter terminal, with the positive lead at the base terminal (Photo E). A similar measurement indicates that the transistor junction is good. If one of the values is really low, a leakage exists between the two elements.

To test a PNP transistor, place the negative probe to the base terminal and the positive lead to the collector terminal and note the value (Fig. 2). Leave the negative probe at the base terminal and move the positive probe to the emitter terminal. The transistor is normal when the two values are about the same.

The defective transistor may be leaky or open and still appear normal. The transistor junction may be open between the base and collector, or the base and emitter terminals (Photo C). The base terminal is common to the other two elements. You may find a leakage reading between any two elements; the emitter-to-collector terminal is the most common culprit. A normal reading between the base and the other two elements will show a voltage drop in only one direction.

Most transistors can be checked very rapidly in the circuit with the DMM, but a low-resistance path between any two elements, such as a coil, transformer, diode, or low-value resistor, may cause an erroneous reading. Again, when in doubt, lift the emitter terminal from the circuit and make another test.

The Open Transistor

The open transistor will have infinite resistance between the open elements. It's possi-

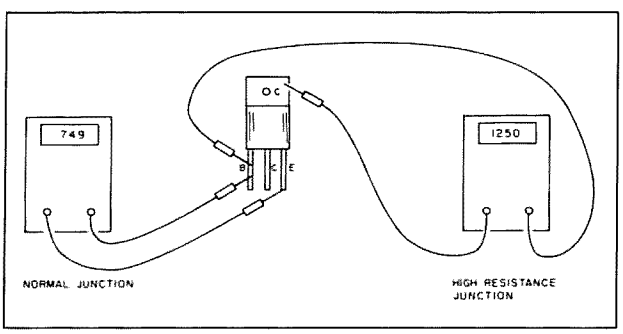

Fig. 3. Although a value might be seen on the display, indicating a junction reading, if the two measurements are not quite close, suspect a high- or low-resistance junction. Replace the transistor.

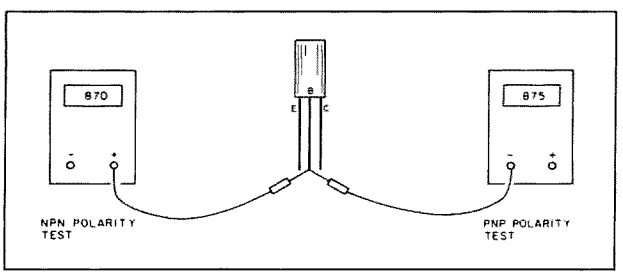

Fig. 4. An NPN or PNP transistor can be identified by observing the polarity of the test leads that result in a display on the DMM.

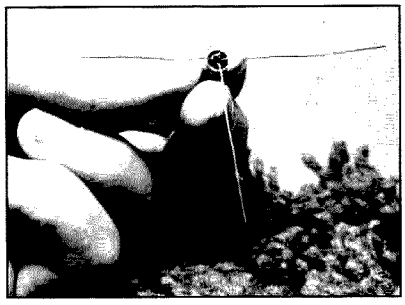

Photo C. The base terminal (bottom center) of the transistor is a common test point for measurement between the collector (top left) and the emitter (top right). A normal transistor will drop voltage in only one direction.

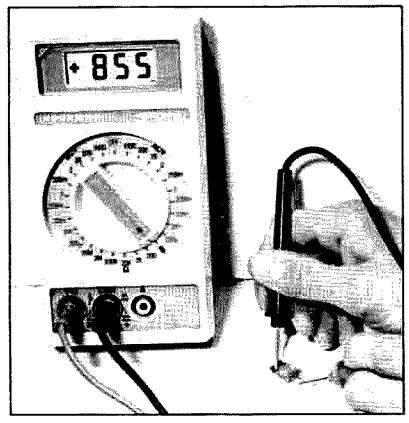

Photo D. Place the positive probe on the base terminal and the negative lead on the collector terminal of an NPN transistor. If the transistor is normal, a measurement can be read.

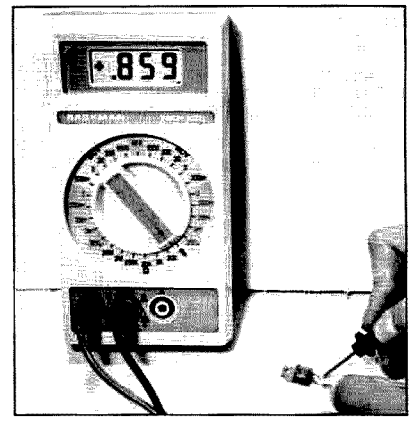

Photo E. Now place the negative probe to the emitter terminal with the positive lead at the base terminal. If the transistor is good, the value should be close to that observed at the collector.

ble to see a normal junction reading between the base and collector terminals and an open indication between the base and emitter terminals. Likewise, an infinite resistance between the base and the collector indicates that the transistor is open.

A transistor never becomes weak like a tube. A poor or high-resistance junction may indicate a defective transistor between the base and either the collector or emitter terminal. For instance, the measurement between the base and emitter terminals may appear normal in an NPN transistor (Fig. 3). When the negative probe is attached to the collector terminal, the reading may be quite high, indicating a high-resistance internal junction. Remember that both measurements should be quite close in a normal transistor.

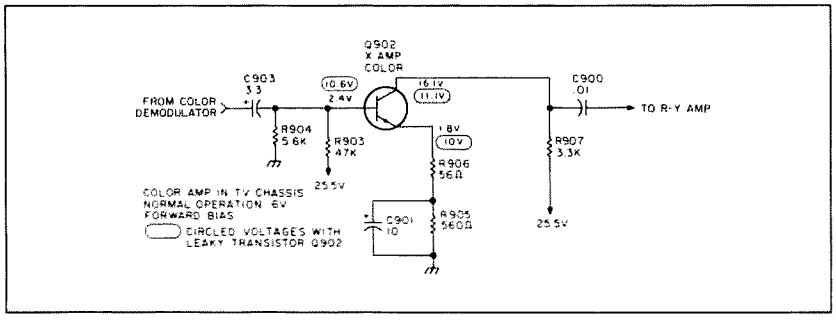

Fig. 5. Critical voltage measurement on the suspected transistor may determine if a transistor is leaky or open. Here, the voltages are quite close on all elements, indicating a leaky transistor.

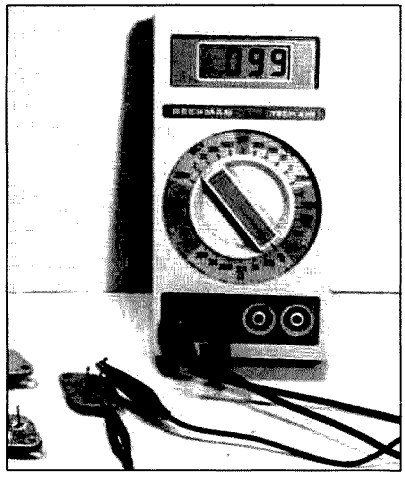

Photo F. A leaky transistor may show a low reading between any two elements in both directions. Here, a 99-Ohm leakage is found between the collector and emitter terminals of an audio-output transistor.

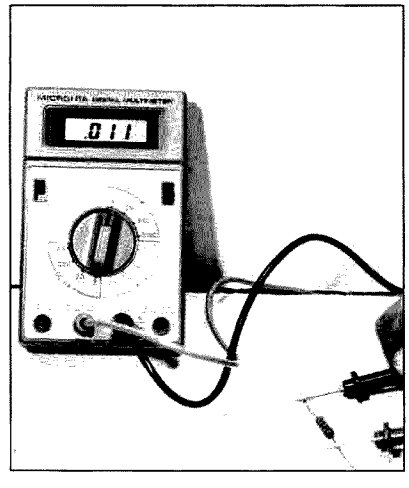

Photo G. Check all resistors for the correct value before replacement. A regular 10-Ohm replacement resistor measures 11 Ohms on the DMM low-value scale—the resistor is within 10%.

The Leaky Transistor

The transistor may appear leaky between any two elements. A leaky transistor will have a low-resistance measurement, from a dead short up to several hundred Ohms (Photo F). To test the transistors for leakage, take a measurement between any two elements. If you reverse the test probes on the same elements and get the the same low measurement, you have a leaky transistor. Leakage measurements above 500 Ohms should be measured on the 20k-Ohm scale. Often the trouble exists between the collector and emitter terminals. Always replace the leaky transistor!

The Intermittent Transistor

A poor junction or internal terminal lead of a transistor may produce an intermittent circuit. Intermittent problems within any electronic device or project are very difficult to locate. Sometimes the intermittent transistor will act up only under load. When tested in or out of the circuit, the transistor may appear normal. Sometimes the transistor will test as intermittent in the circuit, and when removed for accurate tests, the transistor returns to normal. Always replace the transistor under these conditions.

Besides transistor tests, the intermittent transistor can be located with accurate voltage measurements or coolant. Spray several coats of coolant on the suspected transistor—the transistor may turn on and off.

NPN or PNP Identification

In a radio or receiver without markings on the transistors, it is difficult to tell if the transistor is an NPN or PNP type. The identity of any transistor can be quickly determined with the DMM. Remember, if a reading is indicated with the positive lead of the meter on the transistor's base, and the negative lead alternating between collector and emitter, the transistor is NPN (Fig. 4).

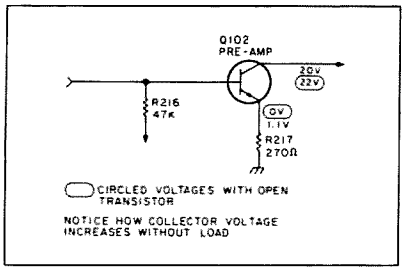

Fig. 6. The high collector voltage indicates an open transistor or emitter resistor (R217). Check the emitter resistor with the low-Ohms range of the DMM.

Once the base terminal is located, the collector and emitter terminals can be identified with voltage measurements. Often, the collector terminal will have a higher positive voltage with an NPN transistor, and the emitter terminal will have a very low voltage. In receivers and audio circuits, the emitter terminal has a low-value resistor between the emitter and chassis ground. Sometimes in TV circuits the emitter terminal itself is grounded.

Transistor Voltage Measurements

Accurate voltage measurements may indicate if a transistor is open or leaky. Suspect a leaky transistor when the voltages are similar at all three terminals (Fig. 5). A higher than normal collector voltage may indicate an open transistor. A low voltage at the collector terminal may indicate a leaky transistor or an improper voltage source. Check the voltage at the emitter terminal—no voltage may indicate an open transistor or emitter resistor. Check the emitter-bias resistor using the low-resistance scale of the DMM.

With the transistor in operation, measure the bias voltage between the emitter and base terminals. Be careful not to short the two terminals! An NPN transistor will have a .6-volt measurement, indicating that the transistor is normal, while the forward-bias voltage of a PNP transistor is only .3 volts. In most cases, when an accurate forward-bias voltage is measured between the base and emitter terminals, you can assume that the transistor is normal. Today, most commercial electronic systems use NPN transistors exclusively.

Resistance Measurements

Resistance measurements within the transistor and diode circuits are quite accurate when using the DMM. The low-resistance range may be used to check for open emitter-bias resistors in TV and audio circuits (Fig. 6). No voltage on the collector terminal of the transistor may indicate an open collector resistor or coil winding.

It's best to remove one end of a resistor and then check for correct resistance. Check the replacement resistor for the correct value before installing it (Photo G)—you may have misread the color code or the resistance may not be what is marked.

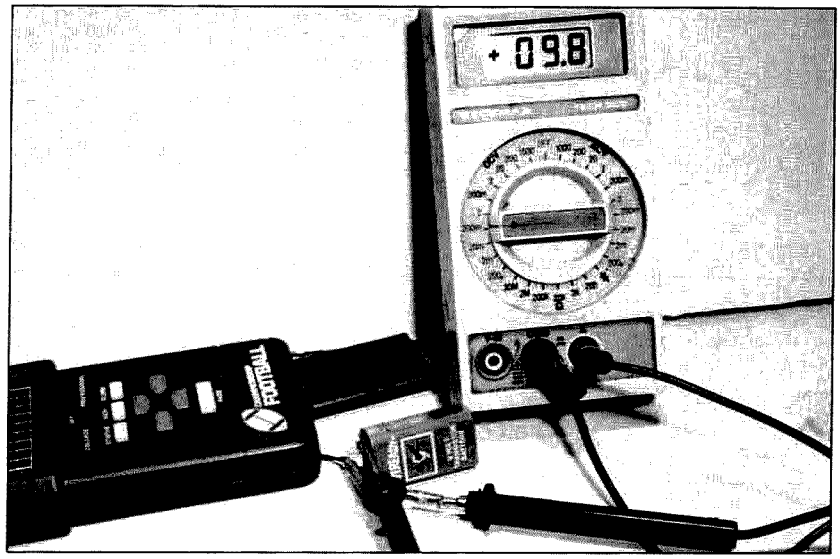

Photo H. Check the current drain if batteries die quickly.

DMM Problems

After many hours of use, your digital multimeter may come up with a few service problems. If measurement is erratic or there are no resistance or voltage measurements, suspect a broken test lead. The probe leads tend to break right at the end of the probe, or where the lead enters the banana jack. Cut off the broken lead and repair the probe terminal. Sometimes it's best to have another set of test leads handy if the meter is used a lot.

Erratic or intermittent measurements may be caused by the banana-type plugs on the meter. Sometimes these plugs get dirty and cause erratic readings of the meter. Rotate the function switch to the low-resistance scale. Hold the test probe together to get a zero reading. Now, flex the cable and move the plugs at the meter. Suspect dirty contacts if the meter reading rapidly changes. Clean up the female contact jack and spread the male banana plug sections for a tighter fit.

A dim LCD may be caused by a weak battery. Some DMMs have a battery indicator that produces a signal when the battery becomes weak. The LCD letters or over-range value will be really dark with a set of new batteries. If the digital multimeter is not used very much, the batteries may become defective from normal shelf life.

How to Check Power-Supply Circuits

Shorted or leaky diodes are a common problem in low-voltage power supplies. The leaky diode can blow the fuse or destroy the primary winding of a transformer in radios or tape players. Sometimes lightning strikes the power line and destroys the silicon diodes. You may find two diodes in a full-wave rectifier circuit or four in a bridge-rectifier circuit (Fig. 7).

Use the diode-test position of the DMM. Lift one lead of each diode in the circuit. A normal diode will show a resistance measurement in only one direction. Replace each

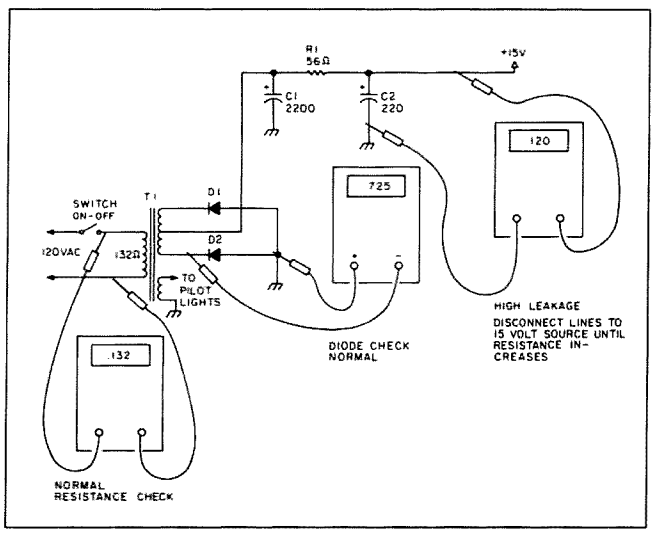

Fig. 7. You may find two diodes in a full-wave rectifier with four diodes in a bridge-rectifier circuit. Remove one end of each diode for leakage tests.

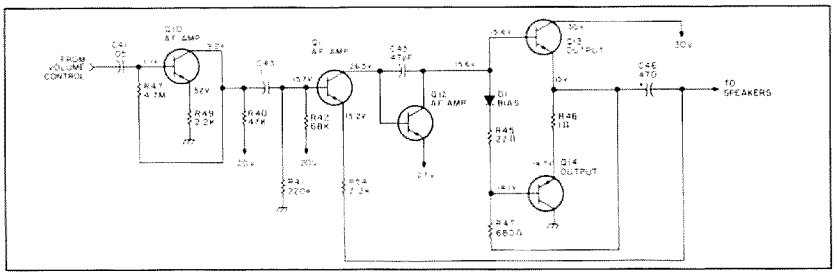

Fig. 8. All transistors in the audio circuit can be checked very quickly with the DMM. Check bias diodes and resistors if the sound is distorted.

leaky or shorted diode. The diode body area may be burned or damaged, indicating lightning or heavy-current damage.

Check the resistance of the primary winding of the transformer (T1) if one or more diodes are leaky. Sometimes a dead short on the secondary winding will open up the primary winding of the transformer. If the diodes appear warm after installation, check the power-supply load or connecting circuits for possible leakage. C1 may be leaky. Check the resistance across C1 for a low measurement. Remove all the load wires connected to the positive terminal of C1 if a very low resistance is found. Then check each connecting load wire for the shorted component.

How to Check Audio Circuits

Some type of an audio circuit is found in practically all consumer electronic products. Dead, weak, or distorted audio circuits can be checked within minutes with the digital multimeter (Fig 8). Here is an audio-circuit service procedure: Quickly check af amps Q10, Q11, and Q12 with the diode-transistor test of the DMM. These three transistors can be checked in the circuit without any problems. A leaky or open af transistor may cause a weak or dead audio circuit.

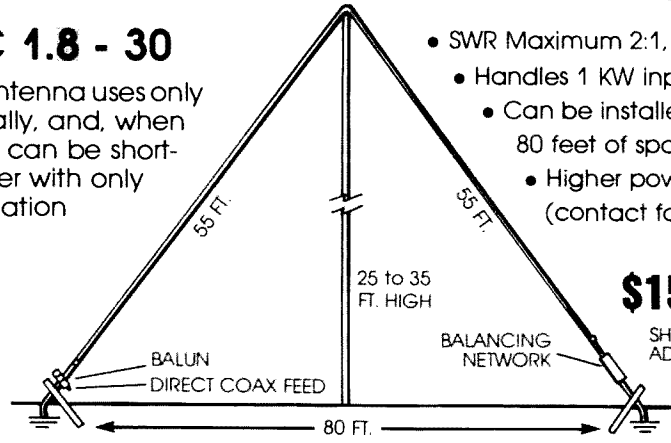
Quickly check Q13 and Q14 in the circuit for open conditions. If leakage is noted between two elements, remove the transistor and test it out of the circuit. A leaky or open output transistor may produce a weak and distorted sound. Check each bias resistor (R46, R45, and R47) with Q14 out of the circuit. Often, a leaky or shorted transistor may destroy the bias resistor. Remove one end of D1 and check for leakage. A leaky bias diode may cause distortion in the sound. By now you should have located the defective component.

How to Check Your Favorite Project

You can quickly check out your favorite project or game machine with the digital multimeter. Simply check all transistors and diodes for proper values. Take critical voltage measurements on the transistor terminals and also determine if the correct voltage source is being fed to the integrated circuits.

Various resistors and momentary push-button switches can be checked for continuity with the low-value scale. Often, a dirty or poor switch contact may prevent a project from working. Lift one lead of the resistor.

When the project will not operate, suspect a leaky component that is causing the unit to draw excessive current. If the project is operated from batteries, measure the voltage across the battery terminals with the unit operating. A low battery reading may indicate a defective component. Place the test probes of the DMM in series with the battery leads and take a current measurement (Photo H).



Remember, your project may not work because of a *new* defective part! Just because the component is new doesn't mean it's okay. Check it out with the DMM. If your favorite project is collecting dust, dig it out, dust it off, and give the DMM a try at locating the defective component or bad connection. ■

NEW from BARKER & WILLIAMSON !

1.8 - 30 MHz. Continuous Coverage Antenna for Commercial and Amateur Service

Model AC 1.8 - 30

The AC 1.8 - 30 Antenna uses only 80 feet horizontally, and, when space is limited, can be shortened even further with only slight loss of radiation efficiency.

- SWR Maximum 2:1, 1.4:1 Average
- Handles 1 KW input ICAS
- Can be installed in approximately 80 feet of space
- Higher power models available (contact factory)

$159.50

Greg Swain

Kit Corner: The DSE Radio Direction Finder

Excerpted with permission from the February, 1986, issue of Electronics Australia.

Most readers will be broadly familiar with the concept of a radio direction finder (RDF). A basic RDF consists of a receiver and an antenna which can be rotated on its own axis. The direction of the transmitter is found by rotating the antenna for a signal peak or null.

You can easily demonstrate the effect for yourself using a portable transistor radio fitted with a ferrite rod antenna. By tuning the radio to a station and rotating the radio about its vertical axis, a null will be found in the signal strength. The ferrite rod antenna will then point in the direction of the station.

Of course, this method requires that "fixes" be taken at two or more widely spaced locations in order to find the true location of the transmitter. The exact location of the transmitter is determined by simple triangulation.

The classic application of this radio direction finding technique was in World War II. Many war movies showed how it was possible to track down enemy transmitters using special vans fitted with RDF equipment. Typically, these vans were fitted with a large external loop antenna which could be manually rotated. An operator inside the van listened in on headphones for peaks and dips in the signal strength. Provided the transmitter remained in the one location for long enough, its location could eventually be pinpointed.

The Dick Smith Radio Direction Finder is just the ticket for tracking down illegal transmitters and antisocial radio operators. Depending on the antenna system, it can operate on any band from 50 to 500 MHz and will work with FM receivers ranging from pocket scanners to amateur radio and CB transceivers.

Physically, the radio direction finder consists of two separate units. One contains the control and display electronics, and the other is a special antenna-switching unit (ASU) which is connected to the control unit via a 4-conductor cable.

An electronic "compass" display consisting of 32 LEDs indicates the transmitter bearing. When a signal is received, its relative bearing to the antenna system is indicated by whichever of the 32 LEDs illuminates.

In fixed installations, this allows the compass bearing of the signal to be directly indicated to within ±5.6 degrees. When an RDF unit is installed in a car, successive readings allow you to pinpoint the exact location of the transmitter.

How It Works

The theory of operation is reasonably simple. Radio signals received on a rapidly moving antenna undergo a frequency shift due to the Doppler effect, an effect well known to anyone who has observed a moving car with its horn blowing.

Consider a single antenna mounted on the edge of a rapidly spinning disc (Fig. 1). As the antenna moves towards the source of the rf carrier, the apparent frequency will increase due to the Doppler effect (Fig. 2). Conversely, as the antenna moves away, the frequency will decrease.

Thus, the rotating antenna causes frequency modulation of the received carrier. When this type of antenna is connected to an FM receiver, a tone is heard. By analyzing the phase of this tone, the direction of the transmitter can be determined.

To avoid the obvious drawback of a mechanically rotated system, the Dick Smith RDF simulates a rotating antenna electronically. Four vertical whip antennas are arranged around a circle with a diameter of 0.07–0.4 wavelengths. The antennas are electronically switched clockwise in sequence such that all four antennas are scanned once every 1/1250th of a second.

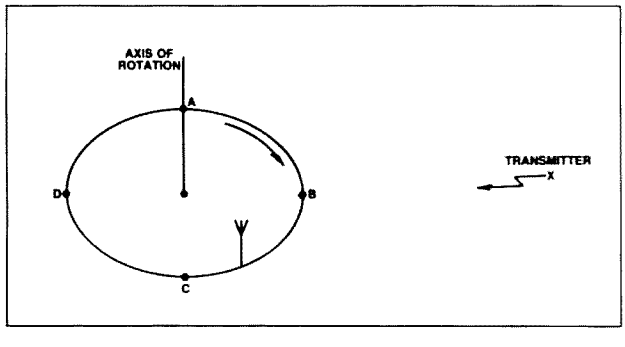

Fig. 1. Signals received by an antenna mounted on the edge of a rotating disc are frequency modulated due to the Doppler effect.

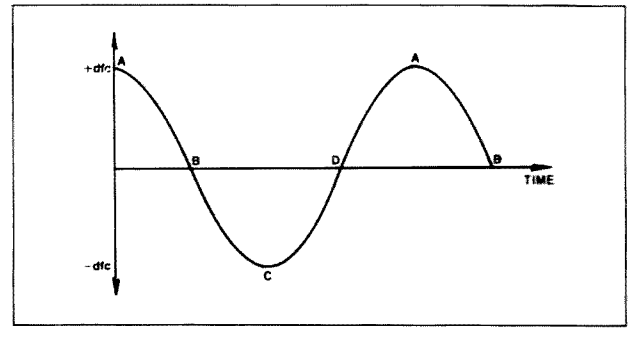

Fig. 2. This graph illustrates the frequency shift as the antenna moves towards and away from the transmitter.

This situation is equivalent to one vertical antenna mounted on the perimeter of a disc spinning at 1250 revolutions per second. A diameter of, say, 800 mm (for the 2-meter band) results in a tangential velocity of 3140 meters per second.

If the carrier frequency is 144 MHz, the carrier will deviate 1.5 kHz at a rate of 1250 Hz. For lower carrier frequencies, the deviation will be proportionally lower. Note, however, that the 1250-Hz modulating tone remains constant, as it is a function of the antenna switching rate only.

The output from the FM receiver is applied to the signal input of the RDF adapter and compared with an internal reference phase. The resultant phase angle appears as a 5-bit binary code which is decoded to a one-of-32 output to drive the appropriate LED indicator.

In addition, the detected audio tone can be monitored on an internal loudspeaker. This provides an audible indication that the receiver is correctly tuned to the transmitter frequency.

The Circuit

Antenna switching is accomplished by first deriving a 2-bit binary code from a 1-MHz master oscillator. Here's how it's done:

Inverter stages IC2a, b, and c (4069) form the 1-MHz oscillator, with buffering provided by IC2d. This clocks decade counters IC4 and IC7, both of which divide by five to produce a 40-kHz signal on pin 1 (CK) of IC10.

IC10 is a 4024 7-stage binary counter. Its Q1–Q5 outputs directly drive the D1–D5 inputs of IC12, a 40174 hex latch, while Q4 and Q5 also drive IC9, which is a 4555 one-of-four decoder.

What happens is that IC9 accepts a 2-bit binary code from IC10 and provides the quadrature antenna-switching signals. These signals are interfaced by a 1488 line driver (IC6). The outputs of IC6 swing positive and negative in sequence to provide bias for the matrix diodes (D201–D208) in the antenna-switching unit (ASU).

The diode matrix is arranged so that, at any given instant, three of the antennas are effectively shorted and only one is coupled to the receiver. For example, when pin 11 of IC6 is low (−9 V), D205–D207 are forward-biased and short out antennas 2 to 4. At the same time, D201 will also be forward-biased while D202–D204 are turned off. Antenna 1 will thus be connected to the receiver.

The detected audio tone from the FM receiver is applied to the input of the RDF adapter, limited by D1 and D2, and filtered by a single-pole active low-pass filter stage (IC5). This chip is described by National Semiconductor as an MF5 Universal Monolithic Switched Capacitor Filter. Basically, it is a general-purpose active-filter building block.

The rest of IC5 is configured as a second-order bandpass filter to remove unwanted audio modulation from the 1250-Hz tone. The center frequency of the filter is set to 1250 Hz by the clock signal applied to pin 8. This clock signal is derived via IC3, which divides the 1-MHz master oscillator signal by eight.

Note that the clock for the bandpass filter is derived from the same source as that used to switch the antennas. This means that the filter is automatically centered on the scanning tone, even when there is some frequency drift.

The output of IC5 (pin 1) is a sine wave with a nominal frequency of 1250 Hz. This signal is applied to op amp IC11a, which functions as a phase shifter. Adjustment of the phase shifter is by means of VR1.

The job of the phase shifter is to allow calibration of the circuit and to compensate for any audio phase shifts in the receiver.

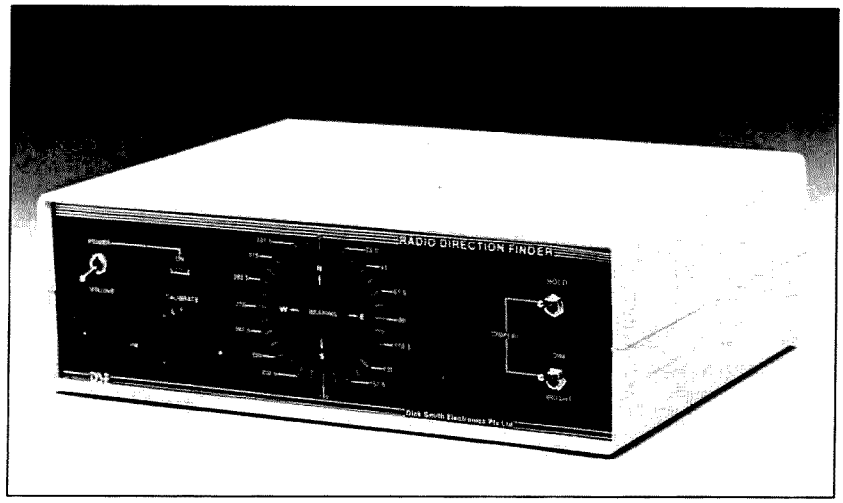
From there, the signal is further processed by a 4046 phase-locked loop (PLL). The function of this stage is to average out any modulation present in the passband of IC5 and to produce a 1250-Hz square wave which is essentially free of noise and jitter.

It is this signal that is used to latch IC12. The output of the PLL (pins 3 and 4) is first inverted by IC2f and applied to D-type flip-flop IC13a. Subsequently, when the flip-flop's D input goes high, IC13a latches IC12 on the first positive-going clock pulse from pin 10 of IC4.

The result of all this is that IC12 is latched with a 5-bit code that is directly related to the transmitter direction. A phase-comparator function is thus performed.

Note that IC13a is necessary to prevent the latching signal from coinciding with a change of data on IC12's inputs.

A pair of 74LS154 one-of-16 decoders (IC101 and IC102) on the display board converts the 5-bit code to a one-of-32 output. These decoders directly drive the 32 display LEDs to indicate that transmitter position.



Switch SW102 allows the display to be held or "frozen" by resetting IC13a. SW101 serves as a power on/off switch, while SW103 allows the display to be dimmed by switching a 330-Ohm resistor into the common anode circuit of the LED display.

To make the unit as easy as possible to use, the audio output from the FM receiver is also fed to an internal loudspeaker. The volume is adjusted by means of potentiometer VR102, which is mounted on the front panel.

Power Supply

Power for the RDF unit is derived from an external 12-V source which connects to a 2-conductor socket on the rear panel. This supplies +12 V direct to several ICs and to the input of 3-terminal regulator IC1. IC1, in turn, supplies a regulated +5-V rail to the remaining ICs.

Op amp IC11b provides a buffered +6-V rail to IC5 and also to the phase-calibration control (VR101).

The Dick Smith Electronics Radio Direction Finder.

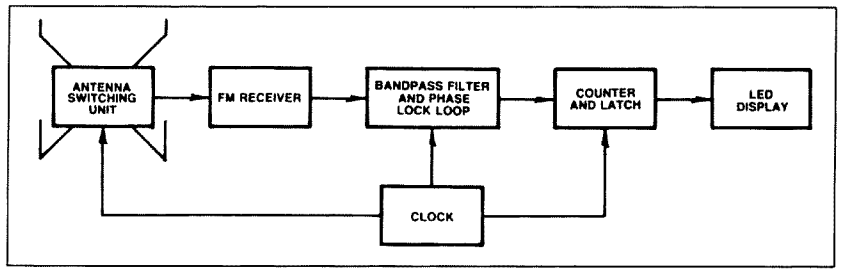


Fig. 3. Block diagram of the Radio Direction Finder. Signals from the antenna-switching unit are fed to an FM receiver and the output is compared to a reference phase.

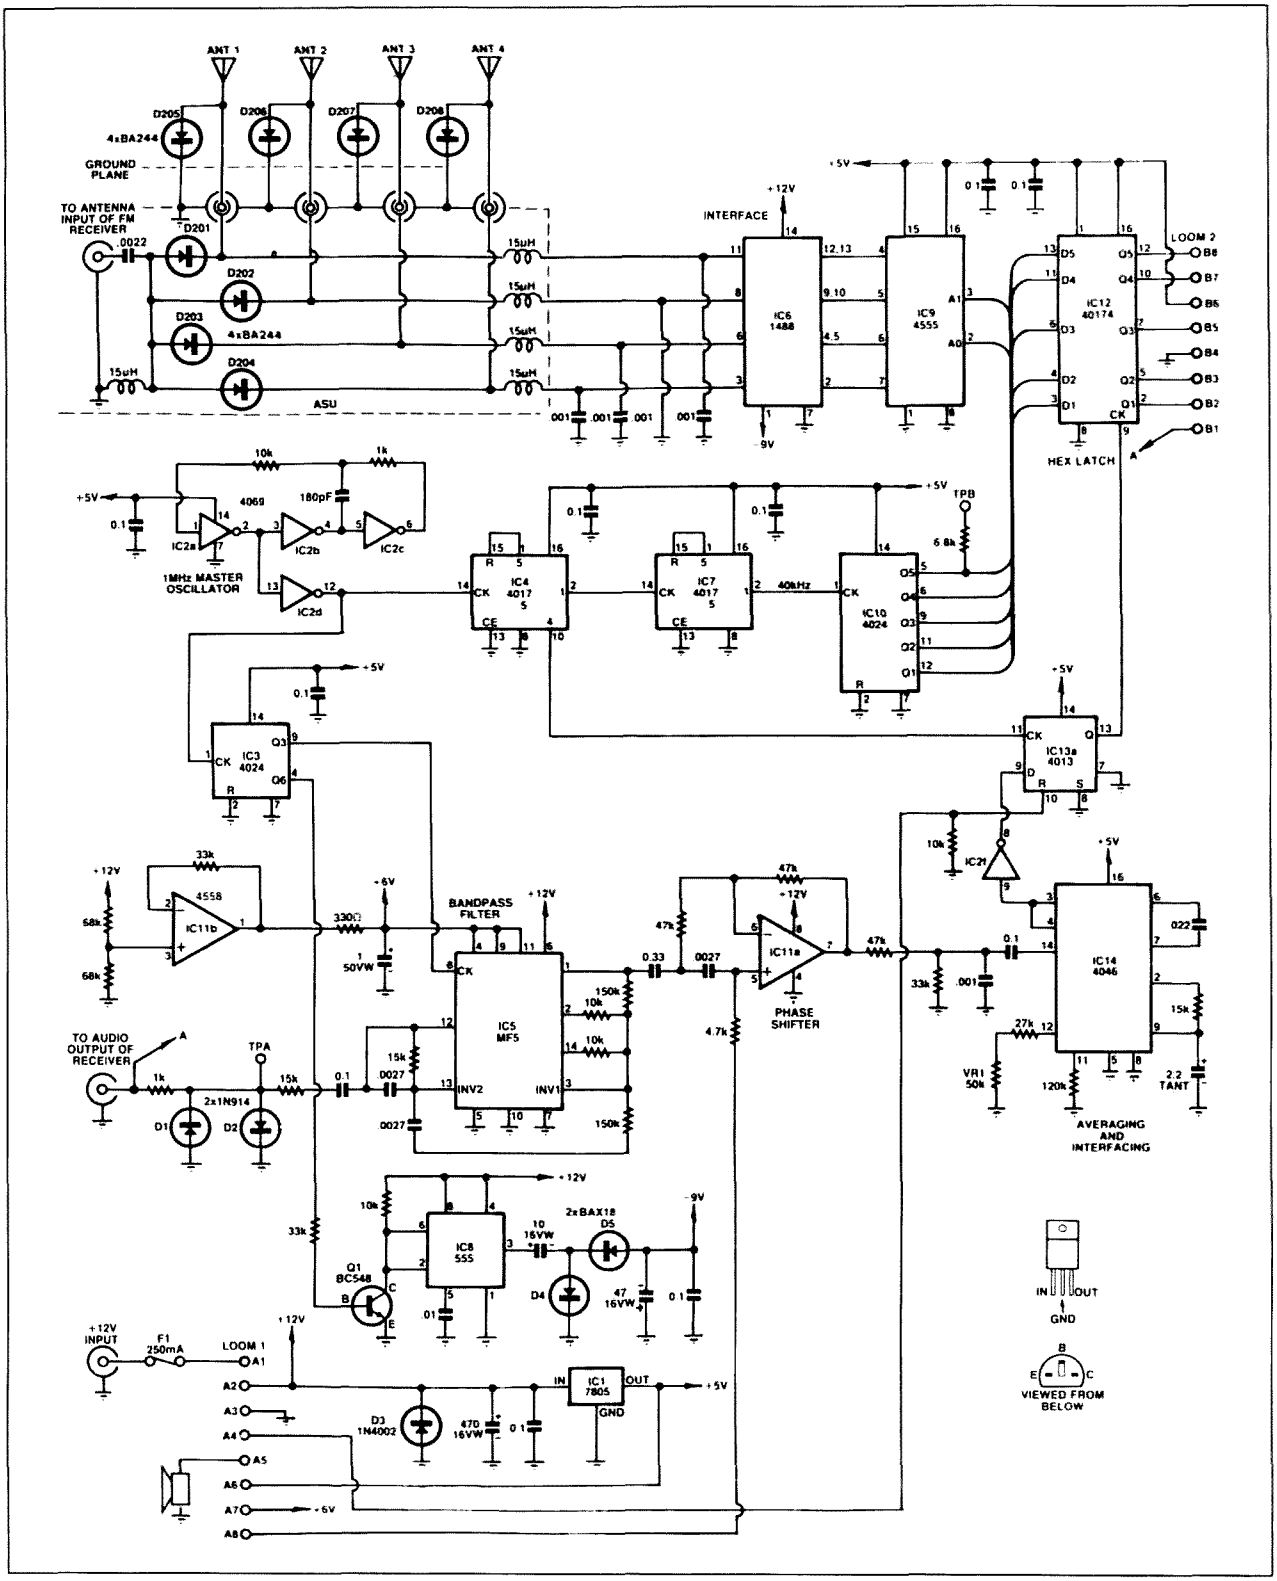

Fig. 4. The control and antenna-switching circuitry.

Finally, a −9-V supply rail is required for the 1488 line-driver IC. This is generated by a dc-to-dc converter circuit based on 555 timer IC8. It buffers a 16-kHz square wave derived from IC3 and drives a diode charge pump based on D4 and D5 to produce the required −9-V rail.

Transistor Q1 simply functions as a switch. Its job is to interface the +5-V CMOS circuit to the +12-V timer circuit.

Construction

Construction is straightforward, with most of the parts mounted on three PC boards, two in the main unit and one in the ASU.

A plastic instrument case fitted with a per-

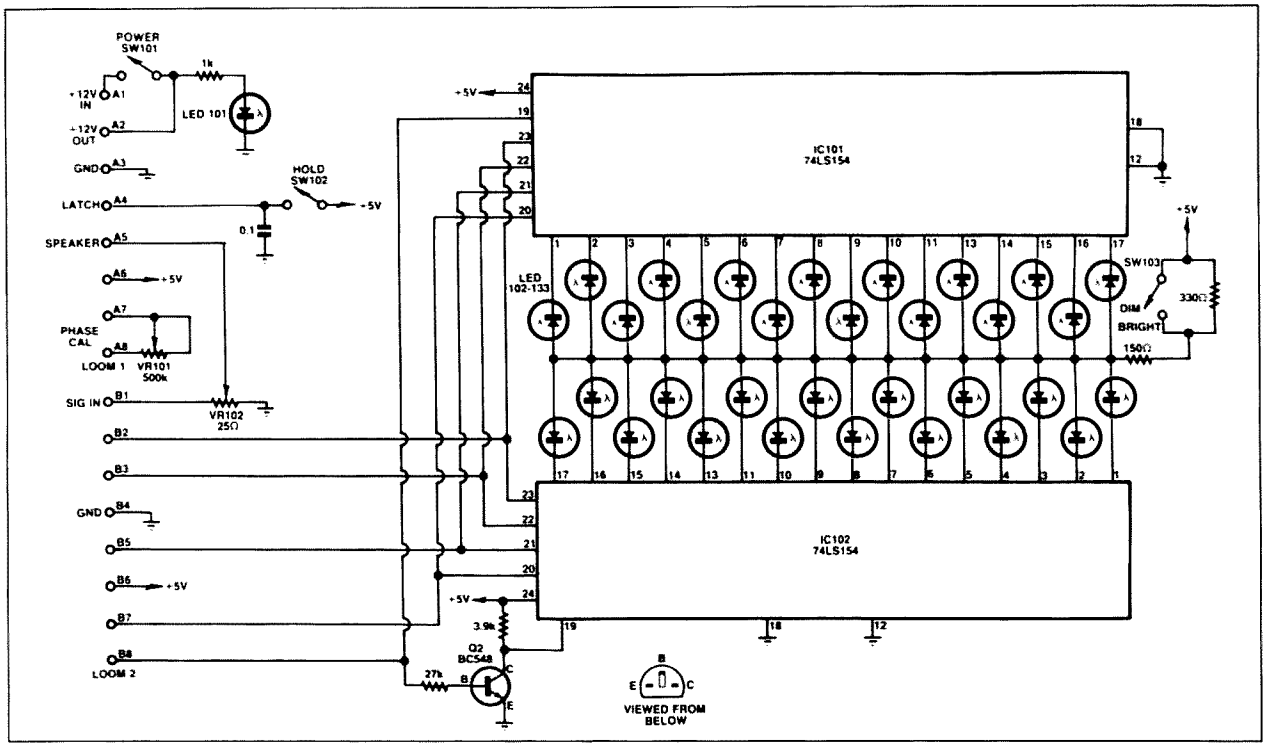

Fig. 5. The display circuit.

spex front panel houses the control electronics, while the ASU board is housed in a plastic project box.

Connections between the ASU and the control unit should be run using 4-conductor cable, while the connection to the FM receiver should be run using coaxial cable. All you have to do is trim the cables to the desired lengths and terminate them with the appropriate plugs.

Note that the wiring connections to the plugs at both ends of the control cable must be made on a one-to-one basis, otherwise the antennas will not rotate in the correct sequence.

Setting Up

An alligator clip lead and a small screwdriver are all that is necessary to adjust the unit.

Connect up a 12-V supply (be careful of polarity!) and switch on with the hold off and the ASU disconnected. All the LEDs in the display should rapidly flicker on and off as the display is scanned.

Assuming all is well, connect the two test points (TPA and TPB) together using the clip lead and adjust VR1 until a single LED is latched. Confirm this adjustment by unhooking and reconnecting the clip lead.

If the display does not latch when the test lead is reconnected, repeat the above procedure. This adjustment brings the vco to within the capture range of the PLL.

Note that, with the calibration control at mid-position, the latched LED should be the one at the top of the circle.

ANTENNAS AND OPERATION

For mobile operation, four 1/4-wave vertical whip antennas attached to a roof-rack assembly would be the best approach. The ASU could then be conveniently located between the antennas. It should be weather-proofed using a silicone sealant.

In most cases, a separate ground plane will have to be provided adjacent to the antenna bases. A suggested method is to secure a sheet of aluminum to the roof-rack. Make sure that the assembly cannot come loose!

A hand-held transceiver can be used to aid the initial setting-up procedure. Depending on the setup, it may be necessary to rotate the antenna array until the compass rose reads true relative to the direction of the vehicle.

The calibration control can be used to make the final adjustment. A walk around the antenna array with the hand-held transceiver will then reveal if the installation is functioning correctly. This should take place in an open area to avoid strong signal reflections.

In the case of a fixed installation, four ground-plane antennas should be mounted symmetrically on a vertical mast, together with the ASU. The array can then be adjusted so that the compass rose displays the true bearing with the calibration control set to mid-position.

Note that, in either case, the distance between opposing antennas should be between 0.07 and 0.4 wavelengths.

If a dual-trace oscilloscope is available, VR1 can be adjusted for a 90° phase angle between the signal input (pin 14, IC14) and the PLL comparator input (pin 3, IC14).

Finally, the control unit can be checked out by connecting outputs 1, 2, 3, and 4 (to the ASU) in sequence to test point TPA. First, connect output 1 to TPA and adjust the calibration control so that the latched LED is at 0°. The 90° LED should now light when output 2 is shorted, the 180° LED when output 3 is shorted, and the 270° LED when output 4 is shorted.

That completes the construction. Your Radio Direction Finder is now ready for use.

Where To Buy The Kit

The Radio Direction Finder described here was developed by the Research and Development Department at Dick Smith Electronics Pty Ltd. It is available as a complete kit of parts by mail order or from your nearest Dick Smith Electronics store.

The kit comes complete and includes a perspex front panel, screenprinted fiberglass PC boards, antenna bases, plugs and sockets, and a detailed construction manual. The cost is $99 plus postage and packing charges where applicable.

Mail orders should be sent to: Dick Smith Electronics, PO Box 8021, Redwood City CA 94063; (800)-332-5373. ■

Falls Church VA 22042

C-64 S-s-s-tutter Fix

WA4BLC tells you how to clean up its act.

I have two Commodore 64s and both have served me well. In fact, I have written six books and a large . . . well, you're not here to listen to all that, but I hope you are here to learn how to fix a small problem that develops with all C-64s at some point in time.

The problem appears first as a missed character, or perhaps as a repeat character, as you type. This is most noticeable when using the computer as a word processor or in RTTY applications. A good example might be:

"Well, guesss thatss abut all here, ssure d hpe to run int yu again. 73 frm WA4BLC in Fallss Church, VA."

Notice how, on some occasions, the letter "s" repeated itself and the letter "o" was missed completely. Both instances are examples of an intermittent problem inherent in the Commodore 64 (and other similar computers).

Background

The Commodore 64 keyboard is made up of typewriter-style key caps which, when depressed, push a small piece of conductive rubber against pads on a printed circuit board (PCB), causing momentary contact. This momentary contact is recognized by the computer, and the particular letter struck will appear on the screen. It is a simple, almost foolproof system giving excellent feel to the keyboard (I compare it favorably to an IBM typewriter), and it is almost immune to accidental strikes or even the occasional physical assault keyboards tend to get.

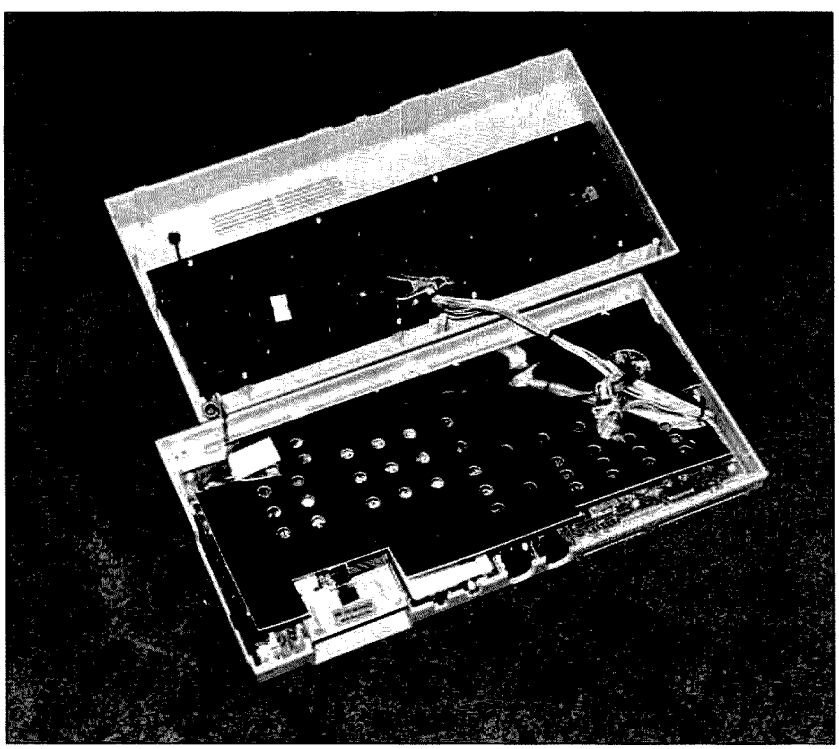

Photo A. Opened up, the bottom half, above, has the keyboard in it. Don't turn it over! Notice the wires referred to in the text that must be unplugged.

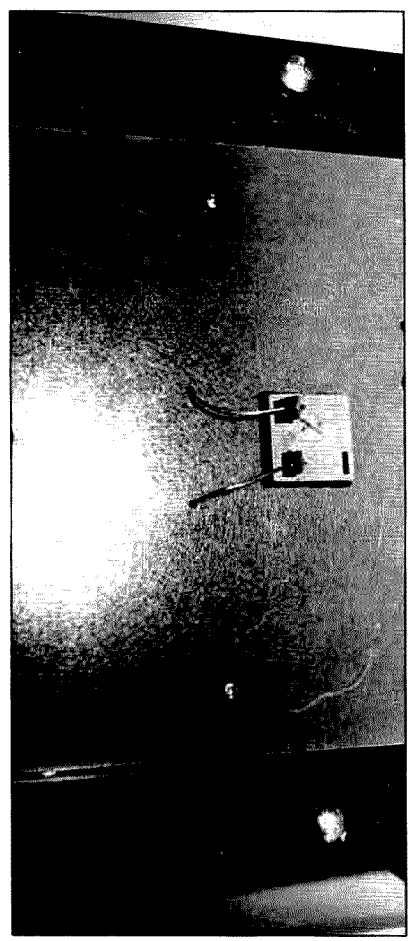

Photo B. These two wires must be unsoldered before disassembly of the keyboard PCB and resoldered when putting it back together.

However, not all is perfect, and from time to time the 64's keyboard will start to skip and stutter, driving the operator up the proverbial wall. After all, we do want our typing and RTTY to be letter-perfect, don't we?

These skips and stutters are caused by a film of oxidation forming on the contact surfaces of the keyboard's PCB. This film prevents the forming of a complete circuit when the conductive rubber contacts the PCB pads.

There are two methods of repair. The first is to take the computer to a repair center, pay the price, and wait the time. The second is to repair it yourself.

Fixing It Yourself

The following instructions are so simple that anyone with the ability to read, to handle a screwdriver, and to solder should be able to repair his own Commodore 64 keyboard.

I recommend you use a small size Phillips screwdriver for work inside the computer (Radio Shack sells kits of small tools) and a cereal bowl for the collection of parts. Use a low-wattage soldering iron—no 250-Watt guns allowed.

1) Disconnect all lines, wires, plugs, etc., from the computer and place it on your working surface with the keys facing away from you.

2) Turn the computer upside down (space bar now underneath and toward you) and remove the three screws along the edge closest to you. After the screws have been removed, lift up the bottom panel until it feels as if it is binding. This binding is caused by three snap-in latches on the back of the computer. Continue to open the computer, and these latches will snap open.

Do not turn the keyboard half of the computer shell over! Leave it face down. If you do turn it over, you will have enough pieces falling and scattering to keep you busy for several hours picking them up and putting them back where they belong!

3) Now that the computer is in two pieces, position them as shown in Photo A, with the insides of each half face up, and the half with the aluminum-foil shield closest to you.

4) Looking at the half of the computer farthest from you, you will see a long, brown printed circuit board. This is the keyboard PCB. On the left side you will see the pair of wires (red and black) which run from the pilot lamp to the bottom of the computer. Unplug this line.

5) Now look at the center of the keyboard PCB and you will see a multicolored bunch of wires. Follow these wires to where you will see them terminate with a plug. Unplug this plug also.

6) Looking on the right side of the circuit board, you will see two bare wires soldered to two lugs. Unsolder these and carefully pull them out of the lugs (see Photo B).

7) Looking at the keyboard PCB, you now will notice 23 small screws, some covered with tape. Remove the tape. Then carefully remove all 23 of the screws (place the screws in the bowl).

8) The keyboard PCB is now free of all connection. Carefully lift it from its mounting and turn it over. The circuit side is green. It is the green side that must be cleaned.

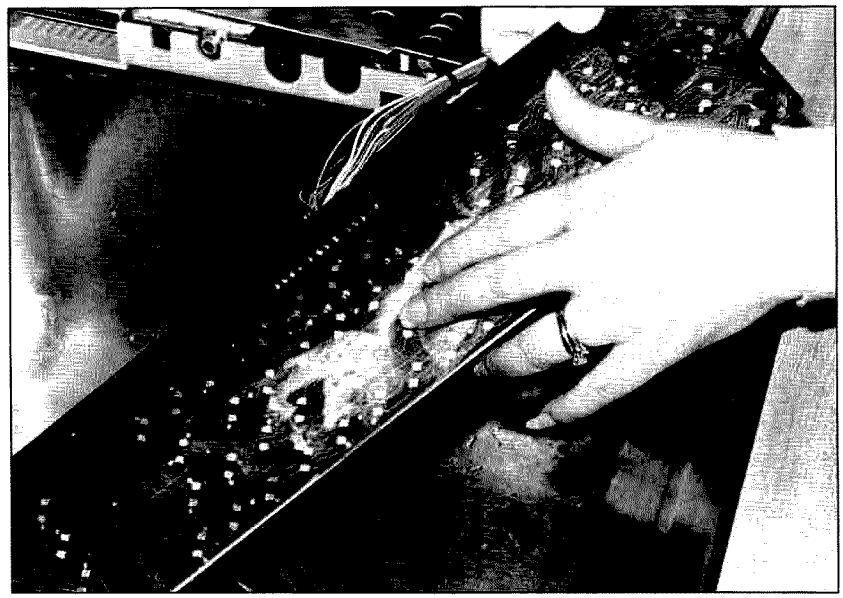

Photo C. Carefully and gently scrub the pads, as instructed in the text.

9) At the kitchen sink, carefully wet the printed circuit side of the PCB and spread about a tablespoon of mildly abrasive bathtub cleaner (the type used on fiberglass showers) over the surface. In addition to the circuit traces on the PCB, you will notice there are many small pads on the board, each about 1/4-inch square. These pads are the key-contact points that need to be cleaned. Using your fingers as scrubbers, lightly scrub each of these pads. Three or four times across each pad will be sufficient (see Photo C).

10) Rinse the circuit board with lots of cool water, then pat dry with a linen towel (linen will not leave any lint). Let the board sit in a cool, dry location for at least three hours to ensure proper drying.

11) Before reassembly, carefully blow the inside of the keyboard shell clear of any accumulated dust and dirt. This can be done with a hairdryer. About 10 seconds of air blast is all that's needed. This short blast will not allow any heat buildup.

12) Place the keyboard PCB back into place in the upper half of the computer, brown side up. There are small round tabs in each corner of the board to aid in alignment. After the circuit board is in place, insert and tighten each of the 23 screws. Do not over-tighten!

13) Resolder the two wires into their respective lugs and plug in the pilot lamp wires and keyboard wire bunch plug. (These plugs are designed to fit only one way, so don't force them.)

14) Place a piece of tape over the group of wires in the center of the PCB. Shipping tape is excellent for this job.

15) Carefully fit the top and bottom parts together, starting with the tabs on the back; reinstall the three bottom screws.

Summary

Well, you may not be a computer service master now, but you surely found a way to save a few dollars. In fact, the dollars saved range from $35 to $95, depending upon where you live and where you take your equipment for servicing.

By the way, dampness and tobacco smoke are the two worst enemies your computer has. Neither is too good for us either! ■

BACK ISSUES

February 1986
HT accessories, more VIC-20 RAM, TR-2400 scanning, FT-101E RIT

March 1986
Wayne's back, extra FT-107 memories, speed dialer, digital IC trainer

April 1986
Stacked vee-beams, curved linear array, Dayton Hamvention, project potting

May 1986
Universal digital frequency display, hula hoop loop, W2NSD/1 on Lids

June 1986
Dirt cheap microwaves, 2 to 10, classic K2ORS humor

You'll also enjoy all of our regular features. Each back issue costs $3.50 plus $1.00 shipping and handling. On orders of 10 or more back issues, there is a flat $7.50 shipping and handling fee. Send your check or money order to 73, Attn: Back Issue Orders, WGE Center, Peterborough NH 03458-1194.

NEVER SAY DIE

from page 12

me, I'll drop your card like stink. Play it fair and square.

Remember, many of our advertisers are hams much like you—except they, in a weak moment, let themselves be talked into going into the ham business. Have pity. Read their ads—circle their numbers—read their literature and let your heart be your only guide. No ham worthy his salt lets his meager pocketbook slow him down. . . right? Remember, the one who dies with the most toys wins. Are you a winner?

A CONFLICT OF INTEREST

Packet radio is looking more and more like the next really big movement in amateur radio—the first since FM and repeaters 15 years ago. But packet has its promoters and its detractors, both with persuasive arguments.

On the plus side, packet requires little expense to be implemented—just your average ham transceiver, a computer, and a packet converter. You really should give it a try. Look over the packet ads in this issue and get cracking.

Okay, now to one of the major problems with packet radio—with the hope that you or your club can come up with some solutions. The FCC has two fundamental rules which they consider important. The first is that anyone transmitting on the ham bands should be licensed. The second is that the ham bands should not be used for commercial communications.

Both are concepts I think we can manage to live with, no matter how frustrating they may be to some amateurs. The problem with packet radio has to do with automatic relaying of messages, often with no record kept of traffic passing through. How can we then be sure that our system isn't used by non-licensed operators? And how can we keep commercialism at bay?

Sure, if relay stations checked out all relayed traffic, we'd have a pretty safe system. But as the volume of traffic passing through builds up, we know darned well that relay stations aren't going to bother reading all the mail. . . or even logging it. Given that inevitability, there will be little control over the use of our networks. Indeed, anyone with a home computer and an inexpensive two-meter rig (which anyone can own) could easily become a regular user with little likelihood of being noticed.

The security of being lost in a crowd would certainly tend to encourage some amateurs (or even non-amateurs) to step over the line of commercialization.

These are things to think over as packet grows in its popularity. The relay station handling a few dozen messages will have plenty of time to read the mail, but as it gets to thousands a day we're going to need some other system of checking.

One possibility might be to encourage relay stations to set up a separate computer just to keep track of relay traffic. They would then have a log of the number of messages handled, the calls originating them, the addressee calls, and the number of bytes relayed. By saving all traffic on a hard disk for a few days they would be able to check out traffic from newcomers to the net, frequent net user traffic, and so on. It isn't perfect, of course, but the knowledge that someone is likely to check out the traffic should act as a lid to discourage illegal use of the system.

The use of 8mm digital video tape to store relayed traffic would make a relatively inexpensive medium for mass storage. We're talking about around two gigabytes of storage per tape cassette. If we figure most messages will be less than one kilobyte, we'll have room for around a million messages per tape. That should hold even a busy relay station for a while.

A new digital audio tape technology is almost upon us—R-DAT, it's called. With this we'll have room for even more data than the 8mm video cassettes, yet they're much smaller than our regular audio cassettes. The 8mm cassettes are about the same size as audio cassettes.

Even our new picocomputers are coming with 3.5" disk drives built in these days. Modern technology allows us to put about one megabyte on these disks, with the promise of 15 megabytes soon. The permanent storing of all traffic shouldn't be a problem for long.

But this is something for our packet fanatics to think about and solve. What say you?

SO WAYNE'S BACK. . . SO?

Let's see, you may be interested in what happened at Orlando—where a lot happened. A whole lot, actually. Golly, where to start? Well, it was a big hamfest—bigger than Miami, I'll bet. Huge indoor flea market. Again, as at Miami, well over a thousand hams stopped by the *73* booth to welcome me back to the magazine. This made me and the whole staff feel good—thanks.

My return to *73*—and I've a bunch more to say about that—was pretty late for the Orlando hamfest to get the word out that I was on their program. I got some flack later on from disappointed hams who missed my talk through a lack of publicity from the hamfest committee. Being so late to get on the program, I had to settle for what they had left in time slots, which wasn't much, and almost no PR.

No, I'm not faulting Ed Huber, the show honcho, who did surprisingly well under very difficult circumstances. My own tendencies toward paranoia are difficult to ignore because every now and then someone leaks the information that "they" really *are* out to get me. For instance, at Orlando I was informed by Al that I'd have an hour and a half to talk, starting at 10 a.m. The show opened at 9, so I knew I'd miss maybe half or more of my possible audience who wouldn't even be there yet. I was not as pleased as you may think to find, on my arrival at a couple minutes to nine, that my talk had mysteriously been changed to 9. Since they didn't even open the doors so people could look it up in a program booklet until 9 a.m., I didn't expect much of a turnout. I was right.

Worse, when I went to the room for my talk, I discovered it had been changed to a different floor. By 9:30 I finally found myself outnumbered and started talking, pacing my talk for an hour instead of an hour and a half. About half way into my talk a chap stuck his head in the door and yelled to say I had to get out because he had the room at 10. Sigh. . . they've done it again!

I polled the small group who did find my talk and found that about a third of them were already active on packet radio. . . and another third were interested. Not exactly a cross-section of amateur radio, but more a cross-section of *73* readers. I'm aiming to have a good deal of information on packet. . . stay tuned.

Epcot

One of the big plusses of Orlando over Miami is the proximity of Disney World and Epcot Center. Since I've visited Disneyland in both Anaheim and Tokyo, I wanted to complete my Disney excursions. I got to the Orlando hamfest a day early and stayed a day late so I could do both Epcot and D World—which I did. No complaints as both were well worth the time.

One thing really disappointed me about the Disney complex—*no* ham activity. If there's any place in the U.S. where amateur radio should have a high profile, it's at Epcot. What a bummer! I met the ham involved with the Disney ham effort and found that he has had little support from the management so far. He mentioned a 7.03 repeater, but I was unable to raise it while there.

The next time I get to Washington I'm going to visit the Florida senators and explain the importance of amateur radio at Epcot. With their support I'll bet I'll be able to get to see the Disney management and explain the benefits to Epcot of having a first-rate ham station.

I talked with Kenwood, ICOM, and Yaesu about supporting a ham exhibit at Epcot and found them all most supportive. I don't know how many millions of people go through Epcot a year, but if the day I was there was typical, it's a bunch—about 50,000 a day. There were lines over a half hour long at the more interesting exhibits. The smart thing to do, as I figured out later, is to head for the country exhibits, which are toward the back end of Epcot and thus not jam packed right after opening time—then move toward the popular exhibits in the afternoon when the lines are short or even nonexistent. Live and learn.

Epcot is like a permanent world's fair. There are enough first-rate exhibits to keep you busy every minute for a complete day. If you sucker in on the long lines it'll take more than a day. You won't want to miss some of the interesting restaurants either. . . for instance, perhaps you've led a sheltered life and haven't ever eaten cous-cous, a Moroccan dish. You'll be able to give it a try while

you're in the Moroccan exhibit. Mmmm.

The 360-degree film in the Chinese exhibit is another must. Spectacular.

If you have any connections which might help us get a ham radio exhibit going at Epcot, please let me know. I'll bet this will take all the clout we can muster. We're going to have to emphasize the benefits to Epcot—how it will help attract the 415,000 hams and their families to the complex—how our advanced amateur radio technologies such as packet radio and OSCAR communications are just what Epcot is all about...people and the future. The Epcot managers should recognize that the key to the future IS communications, and the key to America's future lies in getting youngsters interested in self-education in electronics—just what amateur radio is really about.

The cost to Epcot need not be much more than their current budget. I'm sure we can get the ham industry to provide the equipment and get it installed. One good tech (which they already have on staff) is all that's needed to keep it going and to orient the visiting amateurs. The station operation can be done entirely by visitors. It might be possible to get a major firm as a sponsor, like we almost did with Coca Cola at the New York World's Fair a few years ago.

So, if you know anyone I should talk to about this, please don't make me ask twice. Drop me a note—tell them I'll be in touch—and we'll get moving with this.

Think about it—where else in the whole country is it more important to have amateur radio visible to the general public than at Epcot? And if you look at it from the Epcot view, American radio amateurs are precisely the demographic group they're looking for—middle income families on vacation. The hams will be taking back their Epcot/Disney World slides and videos to show their friends and neighbors.

Am I going to see you next March at Orlando? Will I be on the program? Will I get shafted? Tune in. Better yet, c'mon down! It's during spring vacation for the kids, so jump in your camper and see me before I self-destruct with enthusiasm for amateur radio.

CALL CORRECTION

Whoo, there are a lot of Don Miller hams! I've known three of 'em personally—one was the renowned DXer—the second was into SSTV and an ex-ARRL director—the third was a most interesting American ham living in Mexico City.

The DXer was W9WNV, not W9NTP. Someone mentioned that W9WNV committed suicide recently, but if so I missed hearing about it. I'd heard about him being in jail—something to do with hiring a chap to kill his wife. The SSTVer is W9NTP—my apologies for mixing the similar calls. SSTVer Miller has been going on the October Asian electronic show tours with me...probably why his call came to mind when I was writing about ex-DXer Miller.

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial offices, 73 Magazine, WGE Center, Peterborough, NH 03458-1194.

ACB 50TH
JUN 29–JUL 5

The ACB Radio Amateurs, a special-interest affiliate of the American Council of the Blind, will operate special-event station KW4U from 0000 UTC on June 29 until 2400 UTC on July 5 from the Hilton Hotel in Nashville, Tennessee, the sight of the ACB's silver anniversary convention. Operation will be 80 through 10 meters: 30 kHz from the bottom of CW bands; 5 kHz from the bottom of phone bands (±QRM). For a commemorative certificate, send a QSL to John McCann K4WU, 2105 W. Illinois Street, Arlington VA 22205.

WOODSTOCK 300TH
JUL 4

The Eastern Connecticut ARA will operate special-event station K1MUJ on July 4 from 8 a.m. to 5 p.m. EDT to celebrate the Woodstock, Connecticut, Tercentenary. Operation will be 80 through 10 meters: 40 kHz from the bottom of the CW bands, ±10 kHz from the center of the General phone bands, and packet (frequency and digipeater to be announced on W1AW BBS). Talk-in on 147.225/.825 or 146.52. For a commemorative certificate, send an SASE and QSL card to Tom Francis KB1SP, 73 Second Island Road, Webster MA 01570.

HARRISBURG PA
JUL 4

The Harrisburg RAC will hold its annual Firecracker Hamfest on July 4. Take Exit 1 off of Interstate 238 to Route 441 to the Bressler FC Picnic Grounds. Talk-in on .52. $3 admission. Tailgating free. Tables available. For more information, call Dave KC3MG at (717)-939-4957.

FORT LARAMIE
JUL 4–5

The High Plains ARC will operate special-event station K7YPT at Historic Fort Laramie from 0000 UTC July 4 until 0000 UTC July 5. Frequencies: phone—3.850, 7.250, 14.250, 21.360, and 28.550; CW—50 kHz up from the lower band edges. For a QSL, send a business-size SASE to K7YPT, PO Box T, Torrington WY 82240.

MILL DAYS
JUL 4–5

The Buzzard Roost Repeater Club will operate special-event station WB0UPK from 1500 UTC July 4 to 0100 UTC July 5. This event takes place at the Neligh Mills state historical site in conjunction with the Mill Days festival. Suggested operating frequencies: 3.950, 7.250, 14.295, 21.425, and 28.600 MHz. To obtain a QSL, send an SASE to WB0UPK, 804 East 1st Street, Neligh NE 68756.

SPIRIT FESTIVAL
JUL 4–5

The Heart of America RC and the Johnson County RAC will operate special-event stations from the Kansas City Spirit Festival on July 4–5, from 1800 to 0000 UTC both days, at the Soldiers and Sailors Liberty Memorial in Kansas City, Missouri. The station call for July 4th is W0RR; for July 5th it is W0ERH. Frequency is 7.225 MHz, phone only. Talk-in on 147.27/.87. Admission is $2. The public will be invited to operate the stations under club supervision, so Q-signals are discouraged. QSL via W0RR and W0ERH, PO Box 93, Shawnee Mission KS 66201.

WESTON WV
JUL 4–6

The 27th annual West Virginia State ARRL Convention will be held on July 4–6 at the Jackson's Mill State 4-H Camp near Weston, Lewis County, West Virginia. Free flea-market space for registrants. For more information, contact Sue Goodwin, 103 Cleveland Avenue, Nitro WV 25143.

MEADVILLE PA
JUL 5

The Crawford ARS will sponsor the Firecracker Hamfest on June 5, beginning at 8 a.m., at the Meadville Recreation Center, just off Route 27 E in Meadville, Pennsylvania. Admission is $2; children are free. Swimming costs extra (two pools). Indoor flea-market space is free—bring your own table. Talk-in on 144.53/145.13. For more information, write CARS Hamfest '86, PO Box 653, Meadville PA 16335, or call Ben Ferer KF3F at (814)-724-2432.

TOM SAWYER DAYS
JUL 5–6

The Hannibal (MO) ARC will operate special-event station W0KEM from the Tom Sawyer Days celebration on July 5–6, from 1500 to 2100 UTC both days. Frequencies: phone—7.245, 14.290, 21.400, and 28.770; CW—7.125 and 21.125. For a certificate, send a 9 x 12 SASE and QSL to W0KEM, RR 1, Box 55A, Payson IL 62360.

DOUGLAS WY
JUL 11–13

The Wyoming Hamfest will be held on July 11–13 at the Wyoming State Fairgrounds, Douglas, Wyoming. Amateur exams will be given. For more information, Send an SASE to 1986 Wyoming Ham-

fest, PO Box 3842, Gillette WY 82716-0390.

SAN ANTONIO TX
JUL 11–13

The Texas State ARRL and Texas VHF/FM Society joint convention will take place at the El Tropicano Hotel on July 11–13, beginning at 6 p.m. Friday, from 8 a.m. to 5 p.m. Saturday, and from 9 a.m. to 12 p.m. Sunday. ARRL forum, amateur swap, dealer/manufacturer displays, and preregistered license exams. Convention registration: $5 advance, $7 at door, family $2 advance, $3 at door. Amateur swap tables $5. Talk-in on 148.66 simplex. Send advance reservations to PO Box 18506, San Antonio TX 78218; (512)-698-1712 or 698-0560. Include an SASE for return confirmations. For more information, contact Melvin H. Anderson, Jr. WB5NOL, 8932 Saddle Trail, San Antonio TX 78255; (512)-698-1712 or 698-1714.

PLEASANT GAP PA
JUL 12

The Nittany ARC will hold its annual Mt. Nittany Ham Festival July 12 from 8 a.m. to 4 p.m. at the Firemen's Carnival Grounds in Pleasant Gap, Pennsylvania, 10 miles north of State College off Route 26. Admission is $3 per ham or $5 for flea-market space. Spouses and children free. Talk-in on 146.16/.76 from the north and west; 146.25/.85 from the south and east, and 146.52. For further information, contact Chuck McMullen K3CM, 7 Holly Circle, State College PA 16801.

PETOSKEY MI
JUL 12

The Straits Area ARC will hold a computer demonstration and swap and shop on July 12, from 9 a.m. to 2 p.m., at the Petoskey, Michigan, Fairgrounds. $2.50 donation at the door. Eight-foot table, $3. Splits allowed. Talk-in on .52 and .07/.67. For more information, contact Irene Stein N8HBT or Joe Werden WD8MJB at 4487 Robinson, Pellston MI 49769; (616)-347-8693.

EAU CLAIRE WI
JUL 12

The Eau Claire ARC will hold its annual hamfest on July 12, from 8 a.m. to 4 p.m., at the 4-H Buildings in Eau Claire, Wisconsin. Tickets are $3. For more information, send an SASE to Gene Lieberg KA9DWH, 2840 Saturn Avenue, Eau Claire WI 54703.

OAK CREEK WI
JUL 12

The South Milwaukee ARC will hold its annual swapfest on July 12 at American Legion Post 434, 9327 South Shepard Avenue, Oak Creek, Wisconsin, from about 7 a.m. to about 4 p.m. Amateur-radio exams will be conducted during the day by the Milwaukee Volunteer Core Group. Admission is $3. Talk-in on 146.94 MHz. For further information, including map, write the South Milwaukee ARC, PO Box 102, South Milwaukee WI 53172-0102.

POUGHKEEPSIE NY
JUL 12

The Mt. Beacon Hamfest will be on July 12, from 8 a.m. to 3 p.m. (sellers 7 a.m., auction 2 p.m.), at the Arlington Senior High School, Poughkeepsie/Lagrange, Dutchess County, New York. Big indoor flea market. Admission: $3 (hams and computer hobbyists); $4 with tailgating space; $6 with one free table. Talk-in on 146.37/.97 and 146.52 simplex. For further information, contact Julius Jones W2IHY, RR 2, Vanessa Lane, Staatsburg NY 12580; (914)-889-4933.

MAPLE RIDGE BC
JUL 12–13

The Maple Ridge ARC will sponsor the Maple Ridge Hamfest on July 12–13 at St. Patrick's Center, 22589 121st Avenue, Maple Ridge, British Columbia. Admission is $6, $3 for non-hams over 12, under 12 free, $9 for two hams in a family. Talk-in on 146.20/.80 and 146.34/.94. For more information, contact Bob Haughton VE7BZH, Box 292, Maple Ridge, British Columbia V2X 7G2, Canada; (604)-467-4915.

TEXAS 150TH
JUL 12–13

Special-event station W5SC will be operated from the Texas ARRL and VHF/FM Society convention to commemorate 150 years of Texas independence. Operation will be from 1200 UTC to 0400 UTC on July 12, and from 1200 UTC to 1800 UTC on July 13. Use the lower portions of the 10-, 15-, and 20-meter General CW and phone bands. Send a QSL and an SASE to W5SC, 90 Brees Boulevard, San Antonio TX 78209. For more information, call Andy Anderson WB5NOL at (512)-698-1712.

INDIANAPOLIS IN
JUL 12–13

The IARA will sponsor the 16th annual Indiana ARRL Convention and Indianapolis Hamfest on the weekend of July 12 and 13, at the Marion County Fairgrounds, Indianapolis, Indiana, opening at 6 a.m. each day. Gate admission is $5, with free parking, including overnight camper hookups and facilities. Inside tables are $8. ARRL and technical forums, home-brew display contest, QSL card contest (judging best personal and best-received cards), 2m fox hunt Saturday, 450m fox hunt Sunday. For further information, call Bill Evans WB9BEN at (317)-745-6389.

N. DAKOTA/MANITOBA
JUL 12–13

The 23rd International Hamfest and Computerfest will be held July 12 and 13 at the International Peace Garden between Dunseith, North Dakota, and Boissevain, Manitoba, Canada. Activities include transmitter hunts, mobile judging, and CW contests. Talk-in on .52 simplex. For further information, write MARA, Box 64, Minot ND 58702.

BSA CAMPOREE
JUL 12–20

Scout and Scouters from all over the world, with the assistance of the Southern Connecticut ARA and the Camp Sequassen Alumni Association, will operate a special-event station from the Boy Scouts of America Connecticut International Camporee. The station will be operated July 12–20 from 8 a.m. to 10 p.m. daily. Frequencies: phone—3.940, 7.290, 14.290, 21.360, and 28.990; CW—3.725 and 7.125. Send a QSL and an SASE to the Camp Sequassen Alumni Association, c/o Al Schwartz KA1CFA, 18 Russo Drive, Hamden CT 06518.

BOWLING GREEN OH
JUL 13

The Wood County (Ohio) ARC will sponsor the 22nd annual Ham-A-Rama on July 13 at the Wood County Fairgrounds, Bowling Green, Ohio. Admission is free. Talk-in on 147.18/.78 and 146.52. For more information, contact Chuck Dicken WD8ICP, 1002 Revere Drive, Bowling Green OH 43402; (419)-352-0865.

DOWNERS GROVE IL
JUL 13

The DuPage ARC is sponsoring a hamfest/computerfest on July 13, beginning at 8 a.m., at American Legion Post 80, 4000 Saratoga, Downers Grove, Illinois. Admission is $3 at the gate, $2 in advance. Indoor tables available. VEC exams for all classes. Talk-in on 146.52 simplex. For tickets or reserved tables, send an SASE to: Hamfest Chairman W9DUP, PO Box 71, Clarendon Hills IL 60514; or call (312)-985-0527 evenings and weekends.

WATERTON ALTA
JUL 18–20

The 52nd Glacier-Waterton International Hamfest will be held on July 18–20 at the Waterton Homestead Campground, just north of the Waterton National Park entrance on Highway 6, Alberta, Canada. For more information, write to PO Box 148, Milk River, Alberta T0K 1M0, Canada.

AUGUSTA NJ
JUL 19

The Sussex County ARC will sponsor SCARC '86 on July 19, beginning at 8 a.m., at the Sussex County Fairgrounds, Plains Road, off Route 206, Augusta, New Jersey. Admission is $3. Indoor tables are $7; tailgating space is $5. Talk-in on 147.90/.30 and 146.52. For more information, contact Donald R. Stickle K2OX, Weldon Road, RD#4, Lake Hopatcong NJ 07849; (201)-663-0677.

ATLANTA GA
JUL 19–20

The Atlanta Radio Club will sponsor the 1986 Atlanta HamFestival on July 19–20 at the Georgia World Congress Center, Atlanta, Georgia. Features include over 150 exhibitors and an air-conditioned flea market. For more information, send an SASE to the Atlanta HamFestival, Inc., PO Box 77171, Atlanta GA 30357.

YACHT RACE
JUL 19–20

The Eastern Michigan ARC will operate special-event station K8EPV on July 19–20, from 1400 UTC to 0200 UTC both days, during the annual Port Huron to Macinac Island yacht race. Frequencies: SSB—3.870, 7.235, 14.235; CW—3.710 and 7.110. For a multi-color QSL, send an SASE to C.B.A., 654 Georgia, Marysville MI 48040.

DES MOINES IA
JUL 19–20

The Des Moines RAA will hold the Iowa State Convention from 8 a.m. to 6 p.m. on July 19 and from 8 a.m. to 3 p.m. on July 20. Admission is $3 in advance, $4 at the door. Talk-in on 146.34/.94, 444.50, or 146.22/.82. For more information, write to DMRAA, PO Box 88, Des Moines IA 50301.

WHEELING WV
JUL 20

The Triple State RAC will hold its 8th annual Wheeling Hamfest/Computer Fair on July 20 at Wheeling Park, from 9 a.m. to 4 p.m., rain or shine. Admission is $3 in advance, $4 at door. Talk-in on 146.31/.91. To reserve space, contact Jay Paulovicks KD8GL, RD 3, Box 238, Wheeling WV 26003; (304)-232-6797. For tickets, contact TSRAC, Box 240 RD 1, Adena OH 43901; (614)-546-3930.

WASHINGTON MO
JUL 20

The Zero-Beaters ARC will hold its 24th annual hamfest on July 20, from 8 a.m. to 3 p.m., at Bernie H. Hillerman Park, Washington Fairgrounds, Washington, Missouri. Free flea-market space is available. License exams will be given. Talk-in on 147.84/.24 and .52. For more information, contact the Zero-Beaters ARC, Box 24, Dutzow MO 63342; (314)-239-2072.

FLAT HAMMOCK ISLAND
JUL 20

The Tri-City ARC will operate expedition station KA1BB on July 20, from 1300 to 2000 UTC, from Flat Hammock Island in Fisher Island Sound, New York. This will be only the third time that there has been HF operation from this island. Operation will be in the lower 20 kHz of the phone and CW portions of the 15-, 20-, and 40-meter General-class bands, as well as the center of the 40-meter Novice band. Send a QSL and an SASE to Tri-City ARC, PO Box 686, Groton CT 06340. For more information, contact Bob Dargel KA1BB, 8 Willow Lane, East Lyme CT 06333; (203)-739-8016.

SPACEFLIGHT 25TH
JUL 20–21

The Illinois Valley ARC will operate special-event station KD9UL from 1300 UTC July 20 to 0100 UTC on July 21 to commemorate the 25th anniversary of manned spaceflight—in conjunction with Spaceweek. Frequencies: phone—the bottom 25 kHz of the General phone bands; CW—the bottom 20 kHz of the Novice bands. For a QSL and a certificate, send your QSL and an SASE to Bruce Boston KD9UL, 815 East Third Street, Beardstown IL 62618.

RIVERCADE
JUL 23–27

The Sooland ARA will operate a special-event station on July 23–27, from 5 p.m. to 10 p.m. CDT daily, from the riverfront at the annual Port of Sioux City Rivercade. Operation will be on 14.285 MHz ±10 kHz. Operators will use their own calls but will add "Rivercade" to all CQs and contacts. To receive a certificate, send your contact number and a 9" SASE to Loren Barbee WB0YOW, 1015 16th Street, Sioux City IA 51105.

BIX BIEDERBECK JAZZ FESTIVAL
JUL 25–27

The Davenport Radio Amateur Club will operate special-event station W0BXR during the Bix Biederbeck Memorial Jazz Festival. Times of operation are: July 25, 1700–2200 UTC; July 26, 1500–2300 UTC; July 27, 1600–2200 UTC. Operation will be 80–10 meters, phone and CW, 10 kHz up from the lower end of the General-class bands. For a certificate, send a QSL and an SASE to the Davenport RAC, 2131 Myrtle Street, Davenport IA 52804.

RENTON WA
JUL 25–27

The Western Washington DX Club will host the 34th annual Pacific Northwest DX Convention on July 25, 26, and 27 at the Sheraton Hotel in Renton, Washington. Activities for the DXer and contester; a presentation from Bob Winters KD7P/KH4, recently returned from his Wake Island operation; and a tour of ICOM America, Inc., corporate HQ are included. Tickets purchased before July 1 for all activities are $38 ($42.50 at the door); for programs and banquet, $33; for programs only, $13. For further information, contact Andrew Isar NN7L, Convention Chairman, PO Box 224, Mercer Island WA 98040; (206)-467-1277.

STEAM AND GAS
JUL 26–27

The Pike County ARC will operate special-event station W9CHZ, from 1700 UTC on July 26 until 1700 UTC on July 27, from the 23rd reunion and show of the Antique Steam and Gas Engine Club. Operation will be in the low end of the 75-, 40-, and 15-meter General-class bands, phone and CW. There will also be operation in the 40-meter Novice band on July 26 from 2000–2330 UTC. For an 8 x 10 certificate, send a QSL and an SASE to PCARC, RR1 Box 311, Winslow IN 47598.

W. FRIENDSHIP MD
JUL 27

The Baltimore Radio Amateur Television Society (BRATS) will present the Maryland Hamfest and Computerfest on July 27 at the Howard County Fairgrounds, Rte. 144 at Rte. 32, adjacent to Interstate 70, in West Friendship, Maryland, beginning at 6 a.m. (dealer setups begin Saturday at 2 p.m.—overnight security provided). Tailgating space available for $4; advance reservations required for tables: indoor along the wall with ac outlets, $20 each or 4 for $75; without ac, $10 each or 10 for $95. Free VE exams at 11 a.m., no advance registration required. Talk-in on .63/.03, .16/.76, and .52. For reservations and further information, contact Mayer Zimmerman W3GXK, BRATS, PO Box 5915, Baltimore MD 21208; (301)-655-7812.

HAYS KS
JUL 27

The Hays ARC will hold a swapfest and auction on July 27, from 9 a.m. to 5 p.m., at the Sheridan Coliseum, Fort Hays State University, Hays, Kansas. Admission is $2, tables $1. Activities include VE testing, packet, OSCAR, ATV, video tapes, and fox hunting. Talk-in on 147.78/.18. For more information and reservations, contact Andy Oldham N0EBS, 117 N. 8th St., Wakeeney KS 67672; (913)-743-2712.

OHIO STATE FAIR
AUG 1–17

The Columbus ARA will be operating special-event station W8TO on August 1–17 to promote the Ohio State Fair. Operation will be on 80 through 10 meters. Times and frequencies to be determined by persons manning the booth at the fair (11 a.m. to 9 p.m. EDT daily). A valid exchange includes name, QTH, and RST. For a commemorative certificate, send a log extract or QSL card and an SASE to W8TO, Attn: State Fair Event Coordinator, 280 East Broad St., Columbus OH 43215.

PRO-FOOTBALL WEEKEND
AUG 2–3

The Canton ARC will operate special-event station W8AL to celebrate the Pro-Football Hall of Fame's Greatest Weekend on August 2–3, from 1700 to 2200 UTC each day. Operating frequencies will be: SSB—14.270 and 7.270; CW—14.060 and 7.060. For a special H.O.F. QSL card, send your card with an SASE to Randy Phelps KD8JN, 1226 Delverne Ave. SW, Canton OH 44710.

ANGOLA IN
AUG 3

The Steuben County RA will present their 28th annual FM Picnic and Hamfest at Crooked Lake, Angola, Indiana, on August 3. Two miles north of Angola, I-69 to Crooked Lake exit. Admission is $2.50. Inside tables for exhibitors and vendors available. Talk-in on 146.52 and 147.81/.21.

BERRYVILLE VA
AUG 3

The Shenandoah Valley ARC will sponsor its 36th annual Winchester Hamfest on August 3, from 7 a.m. to 3 p.m., at the Clarke County Ruritan Fairgrounds on Route 7, two miles west of Berryville, Virginia. Admission is $4, women and children under 12 are free. Tailgaters and limited tables $5. Talk-in on 146.22/.82 and 146.52 simplex. For further information, call Rob Kinsley NT4S at (703)-869-5113, or write SVARC at PO Box 139, Winchester VA 22601. Exams on August 2 at 9 a.m.—call Walt Quitter NC4B at (703)-869-5241, or send an SASE to 367 Buckingham Drive, Stephens City VA 22655.

WEST MIFFLIN PA
AUG 3

The South Hills Brass Pounders and Modulators ARC will hold its 49th annual hamfest on August 3 at the south campus of Allegheny Community College, located in West Mifflin, Pennsylvania, about seven miles south of Pittsburgh. Talk-in on 146.13/.73 and 146.52. For further information, contact Doug Wilson WA3ZNP, 185 Orchard Avenue, Emsworth PA 15202; (412)-761-1851.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards or odd-sized scraps of paper. Please type or print your request (neatly!, double-spaced, on an 8-1/2 x 11 sheet of paper and use upper- and lower-case letters where appropriate). Also, please make a 1 look like a 1 not an l—which could be an el or an eye, and so on. Hard as it may be to believe, we are not familiar with every piece of equipment ever manufactured on Earth! Thanks for your cooperation.

I'm looking for the operating and service manual, including the schematic, for an Standart ACS 176 made by Weston Instruments, Inc., in Lexington MA. Will pay for any costs incurred.

I am looking for amateurs who purchased TET Antenna Systems of the HB9CV series. I have the model HB43SP, which works well on 10 and 20 meters but poorly on 15 meters. I have tried to make adjustments as stated in instruction, but these only resulted in a 50-kHz-wide vswr curve. Can any TET owner help? Also, is the TET being made now? If so, where, and by whom (address)?

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

A few months ago, I wrote about the trials and tribulations of a reader who wanted to put a TRS-80 Model 100 computer onto RTTY. At the time, I said that I had no helpful information available. Well, thanks to some others in the fraternity (non-sexist, of course), we have an answer.

Phil W6TUH passed along his thoughts on Model 100 RTTY through CompuServe. He said that he is using his Model 100 with an HF rig (Kenwood TS-520S) via a Kantronics UTU (Universal Terminal Unit). It is easy to set up and works well. The cost is about $200 and *no* software is needed; all software to support RTTY, CW, AMTOR, and ASCII is ROM-resident in the UTU. The unit connects to the Model 100 RS-232 port (STAT=38l1E,10) and to the rig from the external speaker and mike connectors (AFSK)—and can support FSK, as well.

Although he's been at it for 31 years, Phil says that he's not a gung ho ham. But, even though the UTU may not give the ultimate RTTY station, it will work with any computer that can support a dumb-terminal mode and has RS-232 with the required (fairly standard) communications parameters. Phil hasn't used it on VHF, but it appears that connection to a 2-meter rig would be simple.

Phil adds an important caveat: Unless your rig has a special RTTY mode, reduce the dc input to 30–50% of CW value, since duty cycle is 100% on RTTY; otherwise, kiss your finals goodbye!

David Wolovitz WA3DNM of Media, Pennsylvania, sent me some E-mail on CompuServe informing me of a piece of software called RTTY.100 that's available on the Model 100 SIG. Written by Steve Alverson WB8HRV, this is a "mostly BASIC" program that enables the Model 100 to be used as a RTTY terminal.

Steve writes that the program is designed to allow the Model 100 to transmit and receive Baudot (Murray) 5-level RTTY code. Speeds of 60, 66, 75, and 100 wpm are supported. Both received and transmitted text can be echoed to a printer, and the RTS control line can be used for transmitter control.

Program listing 1. RTTY.100.

This program uses the RS-232 port. It requires an external TU (terminal unit) to first convert the receiver audio into RS-232 levels, and then convert it back into tones for transmission. Steve uses a Flesher Corp. TU-300, but any TU with RS-232-compatible signal levels should work. Note that the TU-300 does *not* support RS-232 transmit control—external circuitry is required.

Program Operation

The program begins in receive mode at 60 wpm with echo to printer disabled. Function keys F1 through F4 set the speed to 60, 66, 75, and 100 wpm, respectively. F5 toggles in and out of transmit, F6 sets letters mode and starts a new line, F7 toggles the echo to printer mode, and F8 returns to Menu.

The buffer stores about 30 characters in receive mode, and will transmit them as soon as you select transmit. If you type any character that does not exist in Baudot, you get beeped and nothing is sent. Letters may be typed in upper- or lowercase: They are converted to uppercase before transmission, but are echoed in lowercase (also to the printer, if enabled). This could be useful to differentiate received from transmitted text on a printout.

Steve adds that if he understood more about the LABEL line, he would allow the LABEL key to toggle the last line with a description of the function keys. Any takers??

Machine-Language Calls

Several machine-language calls are used in this program. For those who are interested but who do not have access to references, they are listed below:

16969 (4249H)—Turns on the cursor

19268 (4B44H)—Prints the character in the A reg onto the LCD

27967 (6D3FH)—Prints the character in the A reg onto the LST

28210 (6E32H)—Sends the character in the A reg to the RS-232 port

In addition, a machine-language routine is read into array ML. The entry point at ML(0) checks for received characters. If none are present, it returns with X(0) = 0. If a character has been received, X(0) = 1 and the character is in X(1). The entry at ML(9) converts the character in the A register to uppercase, and places it in the variable pointed to by HL. This allows transmitted text to be typed in lowercase and automatically converted to uppercase (Baudot has no lowercase).

The program itself, RTTY.100, can be downloaded from the Model 100 SIG on CompuServe or, for brave souls with sturdy typing fingers, can be typed in from Program listing 1. Good luck, all, and let me know how it goes. My thanks, again, to Phil, David, and Steve, for all the help and information.

Turning to some paper mail, I have a letter here from Edward Kotz NGØR of Roggen, Colorado. He tells me that he has a second-hand, kit-built HAL ST-5 demodulator and would like to interface it to an RS-232 port for his IBM-compatible NCR PC-6 computer. He wrote to HAL but they said, "The ST-5 was not meant to be used with a computer. . . best solution. . . PCI-2000." No kidding! It seems to him that the price tag is about $600 or more. He wonders if the modification could not be done using optoisolators, relays, or the like.

Well, Edward, I sympathize with you in the amount of information received in response to your request. I have been less than successful in obtaining information from most manufacturers I contact. In the case of the ST-5, I think I have good news for you.

An "FSK" output is available at pin 3 of jack J2 of the constructed ST-5. According to specs, output from this terminal is −15 V on mark and +15 V on space. Sound familiar? You got it, that meets RS-232 specs nicely. Now, in order to get this output, all you should have to do is complete the loop, with a resistor if needed. And that's it!

Now, if you have an ST-5 built from boards, without the "standard" output plugs, you will find the "FSK" output on the power-supply board at a hole between the bodies of R106 (a 8.2k, 1-Watt resistor) and D105 (a 1N4005 diode). Don't forget to close the loop, even if you don't use a conventional RTTY machine. I look forward to hearing how well you do.

Another regular reader, Peter NH6BF/KA6BF/7J6CAG (whew!), says he got onto RTTY with a Heathkit 151, another IBM-compatible computer. He is using KF4NB's software and is having a blast with it. He relates that the major differences between his old CoCo and the Heath setup are disk access, enhanced memory

for traffic, 80-column display, and more bells and whistles throughout. The only problem he says he has is more noise generated by the Heath than the CoCo (ha!).

For further information to the gang, Peter passes along his review of some of the hardware he has used. He feels that the MFJ-1224 interface copies better than an old Kantronics "The Interface," but doesn't stand its ground next to an AEA CP-1 or TONO. The MFJ, he says, requires an S-9 signal for perfect copy, which he needs for volume traffic handling, whereas the AEA copies an S-2. I, for one, would be interested in others' observations and comparisons of these units.

Peter also notes that he has seen a disk-based program for the CoCo that had all kinds of features, like buffers from a disk file, selcal, saving the received information to disk, and disk file transmit. He thinks it was called RTTY64, but he cannot put his hands on the program. Does anyone out there know about this program and where it has been hiding? Tell me, tell me, folks. Let's not keep a good thing secret!

Sometimes I get letters that I just don't know how to answer. Joseph Lerch, Jr. KC3GV writes that he recently purchased an Apple IIc system, and wants to get it onto RTTY. He notes that the IIc does not have a game paddle I/O port, which makes interfacing it more difficult than other Apple IIs. Apparently he has had little luck finding out anything from those around him whom he has contacted. Any of y'all have any suggestions? Pass them along, and I'll forward what I can.

The toughest question he asks, though, is the last one in the letter. He says, "Would you say I made the best choice, or is there a better setup? I can't afford a Commodore, too, and we needed the Apple." I don't know that there is a "best" setup, Joseph. The bottom line has always been what you are using the computer for. If only for RTTY, an inexpensive C-64 or CoCo may well be all that you need. But, if you need an Apple to use other programs, then by all means, buy the Apple. Ditto if you need a PC compatible. You see, there is no easy answer and, when all is said and done, you may not even be happy with one computer for all purposes. The statement may be trite, but "you pays your money and takes your choice!"

On and off, for the last year or so, I have been asking you all what you thought about packet-radio coverage in this column. Reaction has been kind of mixed, so I am pleased to welcome fellow columnist Harold Price NK6K to the pages of *73*, where he has begun writing a column specifically devoted to packet. I know that this is an exciting vanguard area in amateur radio, and I hope that those of you who are experimenting with packet will keep both Harold and me posted on your efforts.

As for me, I continue to hang around here and there, and may even have a new skyhook up by the time this reaches print. If only I can get the bow and arrow working! Of course, I welcome your questions by mail, as well as by E-mail, via my CompuServe ppn 75036,2501. More than a few of you have expressed interest in a feeler I put out regarding a RTTY program for the CoCo. I will continue to play with the idea, and publish what I can right here in RTTY Loop.■

QRP

William R. Stocking W0VM
1030 Weidman Road
Manchester MO 63011

YOU CAN TAKE IT WITH YOU

When vacation time comes around, the OM would like to stay home, operate his radio station, and experiment with antennas. He has had his nose to the grindstone all year and has had little or no time for his favorite hobby. However, his wife is tired of being at home all of the time and would like to have a vacation in the beautiful mountains of Colorado. The kids would also like to go away for a week or two. This family problem *can* have a happy solution! The OM can take a small radio station with him.

Instead of going to the Broadmoor Hotel in Colorado Springs, the family can (for much less money) rent a comfortable cabin in north of Estes Park. With the money thus saved, equipment for a good QRP battery-operated station can be purchased. This is one way of getting money for buying equipment. There is the old saying: Where there is a will, there is a way! If family finances are tight, perhaps a friend will lend the OM a small transceiver for use on the vacation.

What will the OM need for his portable station? In addition to the small transceiver, he will need a power supply and an antenna system. A Ten-Tec Argosy or Argonaut transceiver would be an excellent choice. The Argosy has a switch that shows forward rf power in one position and reflected rf power in its other position. This switch eliminates the need for an swr meter when you use an antenna tuner.

Heathkit QRP transceivers also could be used. The HW-7, 8, and 9 are all usable. The HW-9 is the best of the three because it has a superheterodyne receiver and a bit more power output.

For the power supply, a 12-volt motorcycle battery and an inexpensive battery charger will do the job nicely.

A new Ten-Tec Argosy transceiver without a power supply costs from $600 to $700, depending on how many CW filters or other "extras" are ordered. Used transceivers can be obtained for somewhat less. The Heathkit HW-9, in kit form, sells for around $250 (plus whatever extras are desired). For the power supply, a 12-volt motorcycle battery costs from $25 to $30 and can be kept charged using a small $10 battery charger.

There are several kinds of antenna systems that can be used. A lightweight, easy-to-put-up pole that will knock down into four- or five-foot lengths should be obtained. A telescoping 20-foot fiberglass fishing pole would be ideal for the top part of the pole. Such a pole should be capable of holding up the center of a wire antenna. Although more poles could be used, a single pole will do nicely to hold up the center of an inverted-vee antenna system. Naturally, the taller the pole, the better. Using a pole made of fiberglass or other insulating material is desirable so that a vertical antenna for 20 meters or a higher frequency band could be taped to the pole.

Endfed antennas do not have heavy feedlines and can be made out of lightweight wire. Endfed wire antennas also will work on two or more bands. Of course, an antenna tuner must be used with any endfed antenna. However, if the antenna is a resonant length for the band or bands to be used, a small tuner consisting of a parallel tuned coil can be constructed easily from parts found in a junk box. For a list of resonant length wires, see Table 1. For quarter-wavelength wires for a grounding system, see Table 2.

When you're using an endfed antenna, it is desirable (if not absolutely necessary) to have a quarter-wavelength wire for each band to be used connected to the ground post of the antenna tuner. These wires are sometimes called radials and they can take the place of a ground when it is difficult to get a good ground. These

80 meters—66 feet
40 meters—33 feet
30 meters—23 feet
20 meters—16-1/2 feet
15 meters—11 feet
10 meters—8-1/2 feet

Table 1. Resonant lengths of wire.

135 feet is resonant on the 80-, 40-, 20-, 15-, and 10-meter bands
67 feet is resonant on the 40-, 20-, 15-, and 10-meter bands
46 ft., 2 in. is resonant on the 30-meter band
33 feet is resonant on the 20- and 10-meter bands
22 feet is resonant on the 15-meter band
18 feet is resonant on the 10-meter band (low frequency end)

Table 2. Lengths of quarter-wavelength ground "radial" wires.

RESONANT LENGTHS

A 135-foot wire is resonant on harmonically related bands as follows:
On 80 meters (3.5 MHz) it is a half-wavelength dipole
On 40 meters (7 MHz) it is a one-wavelength dipole
On 20 meters (14 MHz) it is a two-wavelength dipole
On 15 meters (21 MHZ) it is a three-wavelength dipole
On 10 meters (28 MHz) it is a four-wavelength dipole

If you add 5 feet more to one end of the 135-foot wire, it will become a 3/2-wavelength resonant wire for the 30-meter (10.1-MHz) band.

Of course, if the antenna tuner is one which will load up random lengths of wire, the length of the antenna wire can be any "reasonable" length that is at least a quarter-wavelength long for the lowest band to be used. Wires 1/2 to 3/4 wavelengths long at the frequency being used radiate at right angles to the antenna. Wires one wavelength or longer at the frequency being used radiate in a four-leafed-clover directional pattern. However, an inverted-vee configuration will send fairly well in all directions.

wires can be cabled together and run along the baseboard inside the cabin, or go out through the door under the bottom hinge. For an out-of-doors station, the wires can be laid on the ground.

There probably is no need to have a 15-meter radial wire since the 40-meter wire is 3/4 of a wavelength for 15 meters—an odd number of quarter wavelengths. For an excellent discussion of ground radials, see *Simple Low-Cost Wire Antennas for Radio Amateurs* by William I. Orr W6SAI and Stuart D. Cowan W2LX (Chapter 8, "The End Fed, Multi-Band Antenna," pp. 95–98).

It is a good idea to use well-insulated wire for vacation antennas rather than wire that has only enamel for insulation. Well-insulated wire can go out of a building under a window or through a door near a hinge.

Photo A. Pole supporting the fishing rod is lashed to the porch railing.

In a typical cabin, a small table can be placed near a door or window. It can hold the transceiver, the swr meter (if any), the antenna tuner, the telegraph key (or paddle and keyer), the log book, paper, and pen or pencil. The wire from the antenna tuner could go through the door above the top hinge or out under a window, up to the top of the antenna pole, and out and down to a rope tied to a tree, stake, or other suitable object.

On warm days, the family can go on picnics in high-altitude parks. A QRP amateur radio station could be set up on a picnic table. In a location where there is a clear view to the east and northeast, East Coast stations can be worked easily with 5 Watts rf output. It is probable that under good conditions European stations could be worked. Such a station on a picnic table can be used to try out different kinds of antennas. The OM might want to try endfed resonant-length wires for different bands. He might want to try a 135-foot-long wire and find out how well it works on several harmonically related bands (80, 40, 20, 15, and 10 meters—see box).

An interesting antenna to try would be a 33-foot endfed vertical for use on the 20-meter band. Assuming that the pole is made of insulating material, the antenna could be taped to the pole with electricians tape. If the pole is not 33 feet tall, the top part of the 33-foot wire couid be pulled away from the top of the pole by a piece of nylon string fastened to some suitable object.

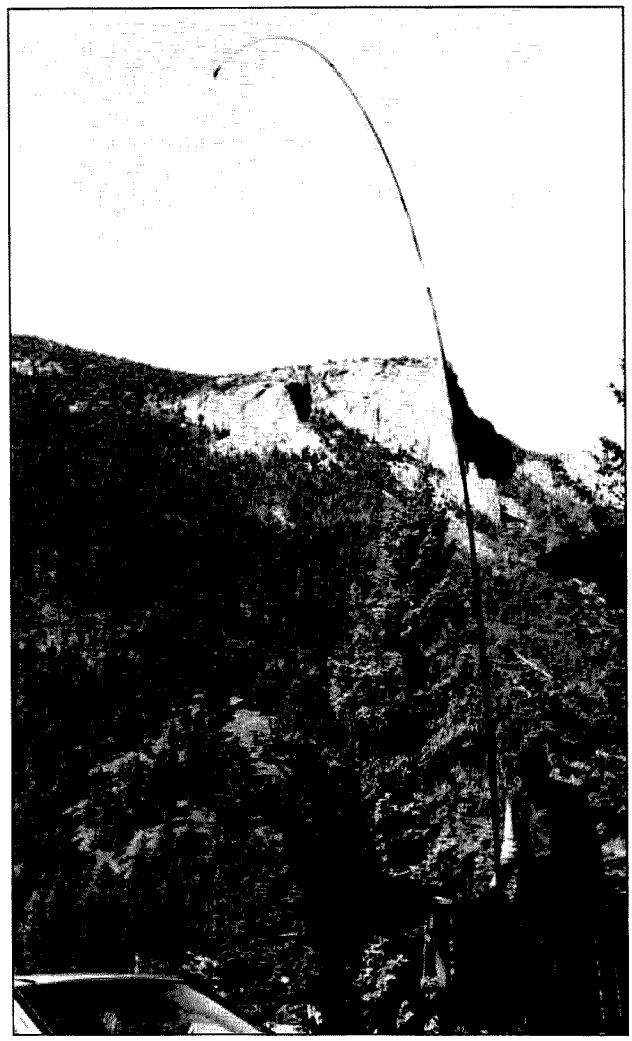

Photo B. Fiberglass fishing pole easily holds up the center of an inverted-vee antenna. W@VM stands beside it.

If one or two other poles were available, a vertical fixed-direction, wide-spaced beam could be put up. A reflector wire 35 feet long could be set up 14 feet behind the endfed antenna so that the line from the reflector to the antenna points in the desired direction. Likewise, a 32-foot wire could be positioned as a director 10-1/2 feet in front of the antenna. A two- or three-element vertical beam aimed towards Europe and located in the clear at a high elevation might well make that QRP rf output sound like 100 Watts to stations in Europe. (The vertical polarization would provide excellent low-angle radiation for "long skip.")

After the desired outdoor antenna experiments have been completed, the station can be set up in the cabin again. The OM then can operate as much as he wants to when he is "at home" in the cabin.

(In June, 1985, I set up a low-power station in a comfortable cabin north of Estes Park. The antenna was a 67-foot- long piece of insulated wire, the center of which was held up by a fiberglass fishing pole. With 6 Watts of rf power, I communicated with stations in St. Louis, Missouri; Dickinson, Texas; and Silver City, New Mexico, on my regular Tuesday evening net on 7.045 MHz. This was lots of fun!)

Since most "comfortable cabins" have ac outlets, the OM could bring his ac-powered home-station transceiver with him, and use it in the cabin.

Yes, you *can* take it with you on vacations, and have lots of fun!■

LOOKING WEST

Saugus CA 91350

THE TIME HAS COME, THE WALRUS SAID

De facto mandatory frequency coordination of amateur repeaters is now a reality, more than a decade after a repeater council in California first requested it. No, I am not blowing hot air. If you were a reader of this column back in 1972 and 1973, then you may remember an organization called the Southern California Repeater Association. Shortly after SCRA was established to coordinate repeater operation in Southern California, its leaders took the initiative to write the FCC to ask for a rule change that would require pre-coordination by a recognized frequency coordinator before the Commission issued an individual a repeater license. SCRA is no more, having been split into separate 2-meter and 1-1/4-meter councils in 1979.

For those of you new to amateur radio, or who have forgotten the way things were in the late 60s to mid-70s, it was a time when you had to request a separate repeater license from the FCC and be issued a distinctive "WR" prefix call for your system. It also meant that being a repeater licensee was a sign of extreme technological competence, since you almost had to hold an EE degree to fill out the required paperwork!

Anyway, the then leaders of SCRA felt that a legislated way of controlling repeater growth patterns was needed, and they turned to the FCC. Their request was simple and, in its day, it made a lot of sense. It also followed the FCC's own pattern of that era toward heavy-handed and highly restrictive regulation of the amateur service, so it was more than a bit of a shock to SCRA when the FCC turned it down cold. In fact, I suspect that it was the rejection by the FCC of this request that made SCRA realize that the heavy-handed repeater regulations of that era could be overturned.

While the ARRL sat dormant on the issue, SCRA took on an advocate's role that eventually led to the termination of the many restrictions that had hindered the technological advancement of this communications format. In the mid-1970s, when the FCC finally agreed to meet with representatives of the amateur community to listen to complaints about repeater rules, only the Southern California Repeater Association, represented by the Palisades Amateur Radio Club of Culver City, flew representatives to Washington for this conclave. As I remember, SCRA was represented by Capt. Richard McKay K6VGP.

You may be wondering why I tell you all this. Well, it's mainly to establish the singular fact that the portion of the amateur rules recently enacted as the result of the Report and Order on P.R. Docket 85-22 is really nothing new. While it's worded differently than it might have been over a decade ago, it is still the same basic concept that SCRA under Charles Flanagan W6OLD, Fred Deeg K6AEH (now N6FD), and several other forward-looking amateurs of the early 1970s requested so long ago. I am not going to tell you that these people were prophets. Rather, they had the ability to form a group mind that understood both the complexities of repeater coordination and human nature. They realized that only through proper regulation of FM-relay technology by the FCC—regulation based upon fairness and logic rather than flat-out restriction—could this mode grow and prosper with minimal confrontation.

Alas, the FCC chose to ignore them, and for 16 years we have suffered with what can only be called "uncontrolled" growth. We have no national band plans except on 220 MHz, and there are many cities where two meters makes the 11-meter Citizens Band seem uncrowded! Had the FCC listened to SCRA in the early 1970s, by now we might have open linking of two-meter repeaters stretching coast-to-coast and border-to-border. Instead, we have big cities where repeaters serving the same geographic area sit five or six deep on a frequency where one system would suffice far more efficiently. We have more "ego box" repeaters than we know what to do with. These are repeaters that are put up and sit unused except by the repeater owner, who chases off of "his machine" anyone who shows up. Not a private or closed repeater in the sense of restrictions on membership, but rather one placed into operation to fulfill the personal ego satisfaction of someone who needs the security of being able to kerchunk his own "box" at will, for reasons I will never understand.

So, for this writer, who has chronicled the story of FM relay communications from almost the dawning of its era, it is interesting to see the Report and Order on P.R. Docket 85-22. It is almost ironic that the FCC is enacting into regulation today what a group of hams requested some 15 years ago. I have to pause and praise the current FCC administration that looks over amateur radio affairs for being a heck of a lot more cognizant of the "real world" than their predecessors were. People like Bob Foosaner, Ray Kowalski, and Johnny Johnston W3BE are the real heart and soul of the part of the FCC that guides the amateur service. Maybe, just maybe, if they had been running the show in Washington back when SCRA made its mandatory coordination request, we would not be suffering from the chaos that we are now.

A recent letter published in *QST*'s "FM-RPT" column lauded the gigantic number of repeaters we have on the air as being a justification for our existence. Bullpucky! We exist not to prove that a fat wallet and matching ego can make us "king of the hill," but rather we exist to serve humanity. It's pretty darned hard to "serve" when you have to fight the intentional QRM of a half-dozen repeaters sharing the same channel! That's nothing to be proud of. Rather, it's sheer stupidity.

I hope that the new rules enacted as the result of P.R. Docket 85-22 will finally remedy all of this, albeit maybe too little, too late. If these new rules do, you can thank Steve Mendelsohn WA2DHF for this one. Steve probably was not aware that his work on getting FCC recognition for repeater frequency coordination was started many, many years ago at a meeting in a high-school auditorium in Los Angeles. Steve is the president of the Tri-State Repeater Council of New York, New Jersey, and Connecticut, and he was the guiding force behind P.R. Docket 85-22. His wisdom and that of those who went before him have given the rest of us a chance at a new beginning. We have the rule, but where do we go from here?

What the Report and Order on 85-22 Means

With the foregoing in mind, it is probably appropriate that it would be Steve Mendelsohn who would be the first amateur-radio media representative to learn of and question the FCC on P.R. Docket 85-22. Steve and his Sony recorder got that chance at the 1986 Dayton Hamvention, when he and FCC Special Services Bureau Chief Raymond A. Kowalski sat down to talk about the issue. While many of you probably heard it on my *Westlink Amateur Radio News* in early May, it is important that as many hams as possible know of and understand the regulatory changes that this rule-making procedure brought with it. Indeed, it affects more than repeater owners and their local coordination councils. In reality, it plays a direct role in the life of every U.S. ham who operates on VHF/UHF FM through a relay device. It affects you. With that in

Enjoying the Hamvention '86 Banquet together are (l–r) Joe Schroeder W9JUV, Dave Bell W6AQ, Ray Kowalski of the FCC, and Steve Mendelsohn WA2DHF.

mind, what follows is the text of that interview:

Mendelsohn: Ray, what does the Report and Order on P.R. Docket 85-22 mean to all of us?

Kowalski: This item was adopted on April 22, 1986, and the rules go into effect on July 12, 1986. We think that there is a great deal of flexibility in the [new] rules, yet make no mistake; there's also a firm indication by the Commission that repeater coordinators perform a valuable function on behalf of everyone who wants to engage in operation in that mode, and the Commission is backing them 100%.

The important outcome of this proceeding is to establish once and for all in the amateur-radio rules, specifically Section 97.85, that when we have cases of harmful interference between repeaters or auxiliary operations, the non-coordinated repeater, if there is one involved, has the *primary responsibility to resolve that interference*!

Mendelsohn: Ray, has the Commission defined what a coordinator is?

Kowalski: Yes, we have. We have added three new definitions [to the rules]. First, there is new Section 97.3 (k) [in which] we define a coordinated station operation. That is, "the repeater or auxiliary operation of an amateur station for which the transmitting and the receiving frequencies have been implemented by the licensee *in accordance with the recommendation of a frequency coordinator*."

Now, you will note that the rule we adopted [also] spoke about harmful interference, and we have a definition for that too. *"Harmful interference is interference which seriously degrades, obstructs, or repeatedly interrupts the operation of a radio communications service."*

Finally, and perhaps most importantly, we have also defined exactly what a frequency coordinator is, and that is *"an individual or an organization [which is] recognized in a local or regional area by amateur-radio operators whose stations are eligible to engage in repeater or auxiliary operation, which recommends frequencies and, where necessary, associated operating and technical parameters for amateur repeater and auxiliary operation, in order to avoid or minimize potential interference."* The first important thing to note is that a frequency coordinator can be an individual. It does not have to be a complex organization with Articles and By-Laws, although they are OK, too. Organizations can be frequency coordinators.

Mendelsohn: What happens in an area that does not have a repeater coordinator or council, or does not feel that it has the need for one? Does that mean repeaters in that geographic region are all uncoordinated?

Kowalski: Areas with sparse populations certainly do not have to go through all of the trouble of setting up a coordinating body just so they can say they have coordinated repeaters. In fact, in the larger cities and in the urban areas where there are frequency coordinating groups, *you can still be an uncoordinated repeater—you had just better not cause interference. If you do, the Commission will look at you [as] the uncoordinated repeater.*

Mendelsohn: What effect will this Report and Order on Docket 85-22 have on Novices if they are eventually given voice and data privileges?

Kowalski: That angle was discussed in the American Radio Relay League's Petition on Novice Enhancement. [Now out for comment as P.R. Docket 86-161—Ed.] What they [the ARRL] asked was that stations in repeater operation be allowed to retransmit signals from Novice-class stations. However, Novice-class licensees could not be the control operator or the station licensee for a station in repeater operation.

In the foregoing, emphasis was added by this writer. What it adds up to is this: Neither the FCC nor a local frequency coordinator can force you to submit to frequency coordination for a repeater you now have in operation or are planning to put up. But that repeater had better not be interfering with one that has been around a longer time than yours. If it does, then you are liable for sanctions from the FCC, and this could be anything from a "nasty-gram" that says "...clean up your act" to a full-fledged Show-Cause Order aimed at license suspension or revocation in difficult cases. In the real world of big-city repeater operation, it says that the days of putting up an unsanctioned repeater are at an end. Regardless of the level of one's ego or bank account, placing a repeater into service now really means that you must obtain the approval of your peers in the local ham community before you do it, because in the real world of amateur-radio FM relay communication, failing to do so will brand you and your repeater as a "pirate" for life. The FCC says that coordination is not mandatory, but in reality it now is. Bye-bye ego-box—it's long overdue that you were buried.

Rural Input

Over the years that I have written Looking West and similar columns on FM and repeater operation, I have mainly concentrated on what's happening in the world of "big-city FM." In fact, the first five years of Looking West dealt solely with the Southern California area and the problems it faced. With the revival of this entity, I really feel that we need a broader base of informational input. A lot has changed since I began writing this column back in 1971. To this end, I am requesting that the more rural areas of our great nation stand up and be counted. You can do this by sitting down and writing to let me know what's happening in your part of the world. The stuff that's interesting will be printed. I need say no more.

Sneak Peak

Next month, in addition to FM and repeater things, you will be treated to my personal theories on the identity of the rather ill-mannered satellite-transponder jammer who calls himself "Captain Midnight." That's the guy who considers himself the "savior of the pay-TV pirates." I do not know his name or address, but I can tell you a lot about him because when he jammed HBO on the evening of April 26th, he left a calling card that any competent broadcast engineer could recognize. It will also, I hope, lead the FCC and FBI to gaining his identity and putting this fellow in jail where he belongs.■

PACKET AT DAYTON

Dayton was its usual self this year. When you put 25,000+ hams in a small area along with at least one of every piece of ham equipment under current manufacture, then add the junk swap outside, you are guaranteeing an interesting time. In addition to the more normal activities, an overheated extension cord caused enough smoke to clear one building for an hour on Saturday, and an electrical problem cut the juice to most of the arena almost all day on Sunday.

Ray Kowalski, head of the Special Services Division of the FCC (which includes amateur radio), and John Johnston, who is directly concerned with amateur rule-making, were there, as well as at least one employee of the enforcement division. It seems that all hams have some sort of subliminal sixth sense that tells them Uncle Charley is near. I saw Ray Kowalski walking around and looking at various displays in the crowded arena, but even under packing densities that would make a megabit RAM-maker cringe, Ray had a clear buffer zone of about 20 feet around him—as if he were shielded by a portable "line of death." Whether it was a chill wind, raised hairs on the back of the neck, or something else, I can't say; I had no such aura and was trapped in the crowd flow, which rapidly carried me out of sight.

The FCC guys have a tough row to hoe. On one hand, they are interested in what's going on and in our thoughts on regulatory issues. On the other hand, various court decisions have enjoined them from receiving comments on pending actions outside of the official comment channels—i.e., in personal conversation. This puts them in the embarrassing position of sometimes having to say, "I can't hear this," such as at the FCC forum, when someone in the crowd insisted on commenting, even after he had been asked not to—repeatedly. The proper way to

comment on rule-making actions is later—as in this month's column.

Speaking of the FCC forum, if you were in Dayton and didn't attend, shame on you! Johnston and Kowalski went over many of the recent and pending FCC actions that affect amateur radio. This included the Novice Enhancement NPRM (notice of proposed rule-making), which would give Novices some digital privileges, and 85-105, the automatic control of packet docket.

They also used the forum to remind us once again that a phone call to the FCC with the question "Is this legal?" is usually a bad idea. Ray Kowalski said, with tongue only partially in cheek, that he has ordered the staff to always respond to that question with a "no." The fact that you are calling, said Kowalski, means that there is some doubt in your mind, and that "no" is the easiest response. As far as I know, a phone opinion is just that, an opinion, and is not legally binding.

New Products at Dayton

If you have made no attempt to chart the growth of packet radio other than to keep your eyes open at Dayton, it is still easy to see packet's increasing effect on amateur radio. This year there were eight booths in which packet was either the only topic or was the centerpiece of the items on display, and most of the dealers had packet equipment for sale. Falcon was selling a packet amplifier. ICOM had a radio that was advertised as packet-compatible. AEA was showing off its HF modem and had HF packets from Italy, Spain, and Norway pouring in. This was even more impressive to the West Coast crowd which usually sees "exotic" calls only on OSCAR 10. There were several packeteers active from the parking lot and flea-market areas. Packet forum coordinator Bob Neben K9BL did a good job this year and scheduled two separate forums on packet—one introductory and one advanced—and both were well attended.

The following is a list of the packet-related products shown for the first time at Dayton. The old standbys, or products that have been out for a while, aren't mentioned. Some of the new ones were still in prototype form. These are not product reviews, and none are necessarily recommended by your humble scribe—I haven't seen most of them in action yet.

AEA

AEA has been one of the most active manufacturers, providing both new software and new hardware capabilities. This year was no exception. The PM-1 HF modem was previously announced, but just started to be shipped in April. This is a unit that can be added to any TNC, and by all reports it is a hot performer. As I said above, it was in use on their demo table, pulling in the DX.

Brand new at Dayton was the AEA PK-232, a Morse/Baudot/ASCII/AMTOR/packet box; it's similar to the PK-64, but it plugs into any computer with a serial port. It comes in two models—one with a modem (PK-232) and one without (UDC-232). A working model was on display. The packet software includes multi-connect and other advanced features, as well as some wrist-slapping messages when you set beacons and timing parameters to channel-hogging values. By the time you read this, these units should be out. No price was announced, but expect to pay more than the cost of packet-only units.

AEA was also showing off a new product that fixes one of the few complaints they've had with the PK-64. The short (too short) flat shielded ribbon cable connecting the PK-64 to the C-64 computer has been replaced with a 24-inch-long shielded flexible cable. This, along with a few software tweaks and an option to include an enhanced HF modem, is sold as the PK-64A. The higher cost of the fancy cable is reflected in the unit's higher price—$269. You can send in your PK-64 and get the new cable put on, but be prepared to pay $70 for the cable, the shielded connector, and the labor. AEA will pay the return shipping.

GLB

GLB has also been busy. A prototype of a 9600-baud rf modem (modem and radio in one box) was on display. High-speed modems will be an important part of the higher-level networks we'll be seeing in the coming months. "How fast can the radio port run?" is one of the questions you should ask when determining which TNC you want to buy. I expect to see many packeteers running faster than 1200 baud as soon as modems become available. GLB did not have a price for their modem, but said it should be ready for beta testing in six to eight weeks.

GLB also had a new TNC on display. This one will be available in the late summer of 1986. Called the PK2, it combines the features of the PK1 and the TNC2A, GLB's TNC-2 clone. In my view, the major fault of GLB's first packet offering, the PK1, was its software HDLC. This limited its radio port to 1200 baud, and also kept it from watching the keyboard and the radio at the same time, in what some have called "quarter-duplex." The new unit fixes this, and its information sheet says, "Full HDLC hardware—no compromises." The user also has the choice of the GLB-style commands or the TAPR TNC commands. GLB's handout had two pages of new hardware and software features. The PK2 will also have the capability to control the frequency on GLB's 9600-baud rf modems. Keep your eye on conventions and ads, as I expect that GLB and AEA will square off in a full-fledged feature war.

ICOM

I'll bet you didn't expect to see ICOM in the packet product list, did you? Neither did I, but on a walk past their booth, I spotted the words "packet-compatible" on the glossy for a new 2-meter radio, the IC-28H. Tom Moore and Jim Newcombe up at ICOM in Washington state tell me that "packet-compatible" means that special care was taken in the design of the radio to ensure a quick transmit/receive turnaround time. They said they believe it to be on the order of 50 ms.

Faster switching time is a good thing. It both increases frequency utilization and reduces the collision window. The shorter the time between when your TNC decides to transmit and when a signal is actually on the air, the less chance there is that someone else will decide the frequency is clear. Thanks go to the ICOM engineering staff for thinking of us, and kudos to the ICOM marketers for realizing the word "packet" sells. A free mention in the column goes to the first person to actually measure the turnaround time on the IC-28H/A and send it in.

MFJ

The MFJ TNC-2 clone, advertised for many months, made its debut a week before Dayton, and a few were in stock with dealers. At a quick glance it seems to be a faithful rendition of a TNC-2. It's in a different cabinet, and TTL levels are brought to a connector in the back for non-RS-232 serial ports.

Microlog

A large sign at the Microlog booth asked, "When is Microlog going to get into packet?" When I asked, the answer was, "We're not sure." The gentleman at the booth must have been asked that question hundreds of times, because the answer was a bit terse. it was Sunday but, on the other hand, it *was* their sign. I gathered that they missed the deadline for showing a packet product at Dayton, a state with which I am well acquainted. Keep an eye on Microlog; their unit may be out by the time you read this.

Pac-Comm

Pac-Comm had a bare board called the PC-100 for show-and-tell. This is a plug-in card for IBM-PC and PC-compatible computers. It has a Zilog 8530 HDLC chip and two AMD7910 modems. With software running on the PC, this puts a dual-port TNC on the PC's bus. This is based on a design by Terry Fox and the AMRAD gang. The PC-100 will be available in July. Pac-Comm was also selling a split-screen terminal package for the PC.

QSKY

Jim Grubbs K9EI of QSKY Publishing has written an introductory-level book on packet called *Get *** CONNECTED to Packet Radio*. It avoids technical details, which is good for an intro, and it includes a large bibliography that points the reader to the more scholarly tomes. The book also contains a large list of packet clubs and other organizations.

TAPR

The big attraction at the TAPR booth was a pin-and-yarn map of North America showing digipeater paths. Everyone who was anyone on packet stopped by to make sure his area was appropriately marked on the map. There wasn't enough time to get a photo of the map in this issue; look for it later.

TAPR had HF tuning-indicator kits for use with TNC-1 or TNC-2 clones. They also had a new introduction to packet video tape. This was done after hours on the news set in a TV studio in St. Louis. An all-ham technical staff was used for the taping. The tape includes "news" quality graphics, runs in just under half an hour, and features packet's best-known video personality, Pete Eaton WB9FLW. The tape is $10 and is not copyrighted.

TAPR also announced that the TNC-2 software source is now a part of the TNC-2 OEM package, and that it would be made available to everyone for noncommercial use in the near future. TAPR's Network Node Controller prototype was also on display.

That's the Dayton report for this year. The revolution rolls on, and it's gaining speed.

DISAGREE WITH WAYNE

Here's a chance to disagree with Wayne. It was rumored at Dayton that Wayne was talking to a group of hams in the crowd and said that maybe there wasn't enough interest among *73* readers to justify a packet column. Maybe he didn't say that, or maybe he was playing devil's advocate, but what the heck, drop him a line and tell him he's wrong anyway.

There was also a rumor that the smoke that cleared the Dayton building on Saturday wasn't an extension cord, but rather was spontaneous combustion caused by a stack of Wayne's editorials. I tend not to believe this, as they looked as if they were stacked a safe distance apart to me.

LETTERS

The first letter about *73*'s new packet column arrived while I was at Dayton. Larry Morgan K7LX wrote to ask for more information about the group in Hamilton with the PC plug-in board. I sent the following off in his SASE:

"The Hamilton Area Packet Network is selling a PC card that features a Bell 202 modem, a watchdog timer, and an 8273 hardware HDLC chip. Software running on the PC turns the board into an internal TNC. The HAPN-1 PC-Packet Adapter, assembled and tested with AX.25 host software, is $199. The address is Box 4466, Station D, Hamilton, Ontario, Canada L8V 4S7."

PETITIONING THE FCC

There are just a few simple rules to follow when you petition the FCC. Rule number one: Make sure people can read your petition. This means type it if at all possible and double-space it. Rule number two: Make some copies and send them along. Send the original and at least five copies. If you want maximum exposure, send an original and 11 copies. Rule number three: Use the standard header on the first page. See Fig. 1 for an example of this header. Mail this petition to the Secretary, Federal Communications Commission, Washington DC 20554. There are many timings involved as to when you can comment, when you can respond to comments, and when you can petition for reconsideration. If you have questions on such items, call the ARRL—dealing with the FCC is one of its major activities.

A detailed description of how to petition the FCC or comment on various FCC actions is given in *The FCC Rule Book*, published by the ARRL. See pages 2-12 through 2-16 in the 1986 edition (green cover).

If you are petitioning the FCC on a packet matter, please send a copy to the ARRL Digital Committee. It's one way we can keep abreast of what's happening, and it's a good way to indirectly notify other organizations such as TAPR, AMRAD, and AMSAT. All of us working together can get things done. The best thing to do is coordinate with the committee before you file, since a request similar to yours from someone else may already be winding its way through the mill. Knowing about it can help you make a better informed presentation of your own to the FCC. You are, of course, free to petition or comment with no coordination, or even file in opposition to the digital committee and other organizations.

WRAPUP

I promised to talk about the IC-02AT, but I've run out of space. I'll cover that and the TH-21AT next month. I also said I'd talk about the automatic control petition, but Dayton took up all the room. Just goes to show that you can't believe everything you read. See you next month.■

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

WHISTLING IN A GRAVEYARD

New York City is full of unique pleasures.

One of these is walking through graveyards. No, I'm not talking about tuning through the upper portion of the AM broadcast band, but honest-to-goodness actual graveyards.

If you have a map of New York handy, whip it out and take a look at the Middle Village-Glendale area. You'll find these amusingly bucolic-sounding towns near the center of the borough of Queens. Although placed inside one of the nation's largest cities, these neighborhoods have managed to keep a suburban flavor by being virtually surrounded by cemeteries. It's a nice, quiet area.

Anyway, my favorite graveyard is located in Brooklyn—Green-Wood Cemetery. Back in the 19th century, it was very fashionable to stroll through Green-Wood's gardens. Although the practice has sort of died out over the years (excuse me), it still can be a fun way to spend a lovely spring day. Just me, my HT, and a few silent friends.

You can find more celebrities lying down in Green-Wood than standing up in Manhattan. Some of the notables I've visited include Horace Greeley, Peter Cooper, Lola Montez, "Boss" Tweed, and William S. Hart. Quite a cast. But I recently reserved a few moments to visit with my favorite Green-Wood resident, Samuel F. B. Morse.

"Sam," I whispered, "the philistines are out to dump your code from ham radio. They say it's keeping newcomers from the hobby."

"Ham what?" replied Sam. I forgot—radio came along after Morse's demise. I filled him in on the details.

"Well, I never was much good at the darn code stuff myself," grumbled Sam. "Couldn't get much above 8 words per minute, actually. God may have wrought the telegraph, but I think a lower force was behind the code."

Sam seemed pleased that we were still using his code after so many years.

"It's a good system," he remarked. "After all, seeing as how you can't talk over wires, it's still the best way to communicate."

When I informed Sam that we can now indeed talk over wires and the air and send written messages as well, he seemed confused.

"Then why use the code?" he asked.

"Tradition," I replied. Sam then muttered something about horse transportation being more traditional than the telegraph, and asked me to move along. He told me to talk to neighbor Charlie Ebbets, of baseball park fame, if I wanted to discuss tradition. He also mentioned something else

about horses that I didn't quite catch.

Comdex vs. Dayton

I hate the people who run the Comdex personal-computer industry trade show. This year, once again, I was forced to miss Dayton to cover Comdex for another publication. Therefore, instead of looking at all the new rigs, swapping DX gossip, and shaking hands with HBO's Captain Midnight, I was forced to fly to Atlanta to talk with computer vendors, distributors, and retailers. Zzzzzz.

Incidentally, the PC market may be following the downward path of ham radio. This year's show featured both fewer exhibitors and attendees. IBM has driven a lot of fun out of the personal-computer business, and we're seeing the results. There weren't a heck of a lot of imaginative products at the show.

Nevertheless, some of the handful of interesting devices at Comdex had their roots in ham radio. I saw a number of wireless modems that drew a lot of their technology from packet-radio devices.

Also, many manufacturers were touting wireless local area networks (LANs). LANs are networking systems that tie together an office's computer work stations and peripherals. A LAN lets employees share data, printers, modems, storage devices, and so on.

Wireless LANs, quite obviously, need radio frequencies to do their thing. A number of LAN makers at the show were literally drooling over our underutilized VHF/UHF frequencies as a possible home for their systems. I heard one company's representative come right out and state that he would like to take away a portion of 220 for his firm's LANs. Incidentally, he described 220 as "an empty band that's assigned to a CB-like service but is hardly used."

Just what ham radio needs, another business interest after our frequencies.

The Puzzle

Callsigns can be fun. Bootleggers have been using them for decades. Ever speak to RG8U from Belden? Yuk, yuk.

David Flynn AA4MN of Nashville, Tennessee, has sent along a quiz that's comprised of funny calls.

His puzzler asks you to match fictional calls with the professions of hypothetical operators. In order for the puzzle to work, the numeral also has to stand for a letter: Ø for O and 1 for I. For example, an American ham in the Midwest who is a dairy farmer might end up with the call KØWS, or a saucy Swedish stewardess might get SM1LE.

Take care, some of the answers are quite subtle.

CONTESTS

Robert W. Baker WB2GFE
15 Windsor Drive
Atco NJ 08004

CANADA DAY CONTEST
Starts: 0000 UTC July 1
Ends: 2400 UTC July 1

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs and everybody works everybody. Entry classes include single operator allband, single operator single band, and multi-operator allband.

Use all bands from 160 to 2 meters on CW and phone combined. All contacts with amateur stations are valid. Stations may be worked twice on each band—once on CW and once on phone. No cross-mode contacts are allowed.

EXCHANGE:

Signal report, consecutive serial number starting with 001, and province. Do not use a separate series of numbers on each band.

SCORING:

Score 10 points for each contact with Canada, 4 points for contacts with others. VE0 counts as Canada and one multiplier. Score 20 bonus points for each contact with any CARF official station using the suffix TCA or VCA. That means an official station counts 10 points plus 20 bonus points for a total of 30 points!

Multipliers are the number of Canadian provinces/territories worked on each band, on each mode (13 provinces/territories per band and mode maximum). Contacts with stations outside Canada count for points but not multipliers.

Provinces and territories are: VO1/VO2, VE1-NB, VE1-NS, VE1-PEI, VE2, VE3, VE4, VE5, VE6, VE7, VE8, VE0, and VY1.

FREQUENCIES:

1.810, 1.840, 3.525, 3.775, 7.025, 7.070, 7.155, 14.025, 14.150, 21.025, 21.250, 28.025, 28.500, 50.040, 50.110, 144.090, and 146.52. Suggest phone on the hour, CW on the half hour. Since this is a Canadian-sponsored contest, remember to stay within the legal frequencies for your country!

AWARDS:

Certificates will be awarded to the highest score in each category in each province/territory, in the U.S.A., and in each DXCC country. Additionally, trophies will be awarded to the top single-op allband and multi-op allband stations.

ENTRIES:

A valid entry must contain log sheets, dupe sheets, a cover sheet showing claimed QSOs, QSO points, a list of multipliers, and a calculation of final claimed score. Cover sheets and multiplier check lists are available. Entries should be mailed within one month of the contest, with your comments to: CARF Contest, c/o N. Waltho VE6VW, Box 1890, Morinville, AB, Canada T0G 1P0.

Results will be published in *TCA, The Canadian Amateur* magazine. Nonsubscribers should include an SASE for copy of the results.

IARU HF CHAMPIONSHIP
Starts: 1200 UTC July 12
Ends: 1200 UTC July 13

The IARU Administrative Council meeting in Melbourne/Aukland in November, 1985, resulted in several changes in this year's contest. Note the name change this year as well!

The three basic changes include: a 24-hour contest period for both single- and multi-operator stations, all bands between 1.8 and 30 MHz may be used with the exception of the 10-, 18-, and 24-MHz bands, IARU member/society headquarters stations count as additional multipliers and will be recognized by their unique exchange.

This contest is open to all licensed amateurs worldwide. The object is to contact as many other amateurs in as many parts of the

THE TSRAC BNT

NEWSLETTER OF THE MONTH

One of our favorite newsletters makes its second appearance in the NOTM corner this month, *The TSRAC BNT*. This incredible book is the chronicle of the Triple States Radio Amateur Club of Adena, Ohio, and is edited by, well, *you* try to find the editor's name! We couldn't.

The *BNT* violates just about every rule of proper publication. Pages are laid out with all sorts of strange typeface combinations, the text is crooked, photos and figures are pasted down wherever they will fit. But it's FUN to read. In the end, that's all that counts. (Incidentally, we also couldn't figure out what BNT stands for.)

To enter your newsletter in *73*'s Newsletter of the Month Contest, send it to *73* Magazine, WGE Center, Peterborough NH 03458, Attn: Newsletter of the Month.

world as possible using the bands specified above.

Operating categories include:

A) Single operator: phone, CW, and mixed-mode sections. One person performs all operating and logging functions. Use of spotting nets is prohibited. Single-operator stations are allowed only one transmitted signal at any given time.

B) Multi-operator: single transmitter, mixed-mode only. Only one transmitted signal allowed at any given time and you must remain on a band at least 10 minutes at a time. All operators must observe the limits of their license at all times. Only IARU member/society HQ stations may operate simultaneously on more than one band, with one transmitter on each band/mode. Only one HQ station's callsign per member/society is permitted on each band.

Stations may be worked once per band/mode; crossmode, crossband, and repeater QSOs do not count.

EXCHANGE:

IARU member/society HQ stations will send signal report and official IARU member/society abbreviation. All others send signal report and ITU zone.

SCORING:

Count 1 point for each QSO within your ITU zone as well as for each IARU HQ member/society station, 3 points within your continent but different ITU zone, and 5 points with different continents. Multipliers are the total number of ITU zones plus IARU member/society HQ stations worked from all bands. Final score is total number of QSO points times the total multiplier.

ENTRIES:

All entrants are encouraged to use forms available from IARU/ARRL Headquarters; send an SASE or one IRC. Logs must indicate times in UTC, bands, modes, calls, and complete exchanges. Multipliers should be clearly marked in the logs. Cross-check sheets are required if more than 500 QSOs are made. Entries must be postmarked by August 13th; any entry received after mid-October may not be in time to be included in the printed results. Usual conditions of entry and disqualifications apply. Entries should be addressed to ARRL Headquarters, 225 Main Street, Newington CT 06111.

AWARDS:

A certificate will be awarded to the high-scoring CW, phone, mixed-mode, and multi-operator entrant in each state, ITU zone, and DXCC country. In addition, achievement-level awards will be issued to those making at least 250 QSOs or having a multiplier of 50 or more. Additional awards may be made at the discretion of each country's IARU society.

CQ WORLDWIDE VHF WPX CONTEST
Starts: 0000 UTC July 19
Ends: 0000 UTC July 20

This event is sponsored by *CQ* Magazine with SCORE, the Society of Contest Operators and Radio Experimenters of Denville, New Jersey, being the administrative head of the contest committee. In this international VHF/UHF competition, multipliers are prefixes and there are eight levels of competition in each geographic area.

Classes of entry include: single operator, single band; single operator, allband; single operator, single band, low power; single operator, allband, low power; multi-operator, single band; multi-operator, allband; portable (with temporary power source); and FM-only.

Low power is defined as 30 Watts PEP output or less. All transmitters must be located within a 500-meter diameter or within the property limits of the station licensee's address, whichever is greater. The antennas must be connected by wires to the transmitters.

Use all authorized amateur bands and frequencies from 6 meters through 23 cm (50, 70, 144, 220, 432, 902, and 1296 MHz). All modes are allowed for contest credit (as authorized by local law and license class).

A prefix is considered to be the three-letter/number combination which forms the first part of an amateur radio callsign. A station in a callsign area different from that indicated by his callsign is required to sign portable. Special-event, commemorative, and other unique prefix stations are encouraged to participate.

EXCHANGE:

Callsign and "Maidenhead" locator grid square (four digits—e.g., FN20). Signal reports are optional and need not be included in the log entry.

SCORING:

Score 1 point per QSO on 50, 70, or 144 MHz; 2 points per QSO on 220 and 432 MHz; 4 points per QSO on 902 or 1296 MHz. Work stations once per band, regardless of mode. Multiply total QSO points times total number of prefixes worked on each band.

AWARDS:

Engraved trophies will be awarded to the top-scoring stations in each category and major geographic area where competition is indicated. Parchment certificates suitable for framing will be awarded to top-scoring stations in each category and minor geographic area where competition is indicated. Certificates may also be awarded to other top-scoring stations that show outstanding contest effort.

ENTRIES:

Contest entries must be postmarked no later than August 31st to be available for awards. Logs should be mailed to the *CQ* VHF WXP Contest, c/o SCORE, PO Box 1161, Denville NJ 07834, or to *CQ* Magazine, 76 N. Broadway, Hicksville NY 11801.

CW COUNTY HUNTERS CONTEST
Starts: 0000 UTC July 26
Ends: 0200 UTC July 28

MARAC invites all amateurs to participate in this year's contest. All mobile and portable operation in less active counties is welcomed and encouraged. Stations may be worked once on each band, and again if the station has changed counties. Portable or mobile stations changing counties during the contest may repeat contacts for QSO points.

EXCHANGE:

QSO number; category (P for portable, M for mobile); RS(T); state, province, or country; and U.S. county. Stations on county lines give and receive only one QSO number, but each county is valid for a multiplier for the receiving station.

FREQUENCIES:

3.575, 7.055, 14.065, 21.065, and 28.065. On 20 and 40 meters, mobile and portable stations should call CQ or QRZ below the suggested frequencies; fixed stations should call CQ or QRZ above the suggested frequencies.

SCORING:

QSOs with fixed stations are 1 point; QSOs with portable or mobile stations are 3 points. Multiply the sum of all QSO points times the number of U.S. counties worked. Independent cities may be counted as any one of their adjoining counties in accordance with USACA rules. Mobiles and portables calculate their score on the basis of total contacts within a state for the state certificate, and calculate their score on all operation if they operated from more than one state in competition for the High Portable or High Mobile plaque.

AWARDS:

Certificates will be awarded in three categories:

F) Highest fixed or fixed-portable station in each state, province, and country when total score exceeds 1,000 points.

P) Highest station in each state operating portable from a county that is not its normal point of operation, when total score exceeds 1,000 points.

M) Highest station in each state operating mobile from three or more counties (with a minimum of 10 QSOs in each of three counties).

Plaques will be awarded to the highest mobile, portable, and fixed stations in the United States that meet the above requirements for certificates. Additional awards will be issued when deemed appropriate.

ENTRIES:

Logs must show category, date/time in UTC, station worked, band, exchange, QSO points, location, and claimed score. All entries with 100 or more QSOs *must include a check sheet of counties worked or they will be disqualified from receiving awards*. Enclose a *large* SASE if results are desired. Logs must be postmarked by September 1st and sent to: Jerry Burkhead N6QA, 7525 Baltic Street, San Diego CA 92111.

ABOVE AND BEYOND

Peter H. Putman KT2B
84 Burnham Road
Morris Plains NJ 07950

As this is being written, the last days of winter have gone by and spring is well along, bringing the first thunderstorms of the year and with them the attendant sporadic-E (Es) conditions that make six meters so much fun to operate during contests!

The 1986 ARRL June VHF QSO Party will long be history by the time you read this, but no doubt some Es will have been observed during the festivities and many new grids worked. It's long been a truism that if you really want to make a big score in this particular contest, you can't neglect six meters. I'll briefly relate some of the details of an operation our contest group undertook in the 1984 June VHF QSO Party under the callsign K2XR.

This was intended to be a major effort, with kW amplifiers on each of four bands—50, 144, 220, and 432 MHz. In addition, we ran 100 Watts on 1296 MHz. All of the stations used stacked yagis on good-sized towers, and the location was far enough away from prying eyes, man-made interference, and noise so as to ensure a reasonably quiet operation. Our six-meter station in particular was designed for maximum effort: It used an ICOM 551D driving a home-brew 4-1000A amplifier at the legal limit. This in turn fed two KLM 50-LD 7-element beams stacked on a 70-foot tower/mast combination.

Well, the conditions were certainly ripe for Es! This had to be one of the hottest weekends I've ever spent anywhere, and being at 1400' ASL didn't help one bit. The mercury went over the 100-degree mark several times during the weekend and stayed there, baking our crew unmercifully. We consumed gallons (and I *mean* gallons) of beverages over the weekend just to stay cool. Every fan we could employ was put into service, and most of the crew never had more than a pair of shorts on all weekend, even at night. It was *that* hot.

With the sustained high temperatures and reports of thunderstorm activity across the nation, it was only a matter of time before we would get our first big opening. But we didn't expect it to come Saturday night. Sure enough, here were S9++ signals coming in from Nebraska, Texas, Missouri, and Florida. We couldn't get them into the log fast enough.

A Janel 50-MHz MOSFET preamp helped immensely with the receiver, and the amplifier made it possible to bag extra contacts when meteor scatter was present during the wee hours of the morning. The Es opening had pretty much died down by that time, although Es can happen around the clock. Since conditions on the other bands were pretty punk, we concentrated on six meters as much as possible.

That is, until the preamplifier blew up. The intense pounding of rf from the 4-1000A proved to be too much and the preamp made an early exit Sunday morning, complete with the attendant puff of smoke. Conditions were so good by this point due to another Es opening that we really didn't need it anyway! Stations were calling us from Florida, Kansas, the Carolinas, and Oklahoma. Our group certainly was benefiting from the line of thunderstorms in the South, even if we weren't getting any of the cooling rain that came with them. Temperatures remained in the high 90s and many operators went into a cool cellar just to get back into mid-70-degree air.

Our finest hour came on the final night when we bagged additional stations in Alabama, Mississippi, Texas, and North Dakota. All of this was capped off by a contact with the Bahamas! In many cases, K2XR was the only station responded to by these operators after repeated CQs. The 4-1000A behaved very well (although it detonated its plate choke halfway through the weekend) and was the difference in some of the scatter contacts and the weaker Es grids worked. The stacked beams also helped since the angle of radiation during both Es and scatter contacts was relatively low.

Remember, though, that you don't have to run lots of power to take advantage of this phenomenon! Many times the Es is so localized and is intense enough to allow ORP contacts in the 400–600-mile range with ease—sometimes even further. Many owners of IC-502s have been lucky to work into the deep South and Caribbean during such conditions, all with no more than 3 Watts to a whip antenna. If you haven't given six meters a try lately, then a portable operation with 10–100 Watts might just be the ticket.

Keep in mind that in many instances Es on six has provided the only excitement during an otherwise routine June VHF QSO Party. It's a great way to work those rare grids, not to mention rare prefixes during the July *CQ* WW VHF WPX. Generally, the storms that provide the best openings usually occur over the mid-continent area, although storm systems in the deep South will usually provide pretty good openings.

One radio that meets our requirements nicely is the aforementioned IC-551D. This unit is still manufactured by ICOM and features an 80-Watt final with dual vfo's and multimode operation. The difference with the 551D is that it was intended to be first and foremost an SSB/CW rig, with FM thrown in as an afterthought, so the receiver performance on weak signals is very good. An outboard preamp is highly recommended, and it is easily connected via the rear-panel RCA jacks for "RCVR IN" and "RCVR OUT." You'll have to tap into the 551D for a source of 13.8 V dc.

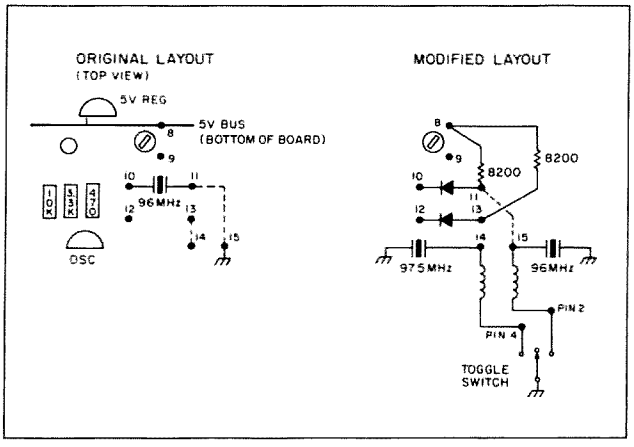

Fig. 1. VE3CRU's modifications to allow dual-range crystal switching on the MMT 220/28.

1. *Remove 96-MHz crystal from pins 10 and 11.*
2. *Remove 10k resistor.*
3. *Install 1N914 diode from pin 10 to pin 11 with cathode at pin 10.*
4. *Install 1N914 diode from pin 12 to pin 13 with cathode at pin 12.*
5. *Remove ground wire from pin 15.*
6. *Install 10-uH choke from pin 15 to DIN socket pin 2.*
7. *Install 10-uH choke from pin 14 to DIN socket pin 4.*
8. *Install 96-MHz crystal from pin 15 to PC foil ground.*
9. *Install 97.5-MHz crystal from pin 14 to PC foil ground.*
10. *Install 8.2k resistor from pin 8 to pin 11.*
11. *Install 8.2k resistor from pin 8 to pin 13.*
12. *Install SPDT center off toggle switch on connector panel above DIN socket.*
13. *Connect center pin of switch to ground.*
14. *Connect pin 2 of DIN plug to one side of switch.*
15. *Connect pin 4 of DIN plug to other side of switch.*

Theory of operation—The crystals are coupled to the oscillator-transistor base via a switching diode. One of the crystals is disabled by grounding the appropriate pin on the DIN socket or by using the toggle switch. The diode on the inactive crystal will be back-biased about 1 volt, thereby disabling it. Using a toggle switch to change the crystals directly is not recommended since the stray capacity across the switch is sufficient to permit oscillation. The toggle switch can be used to select frequency. In the center off position, frequency selection is done remotely by grounding the proper pin on the DIN socket.

(Incidentally, ICOM also made a 10-Watt version of this radio, called the 551, which is still available on the surplus and hamfest market.)

However you choose to do it, six-meter operation can be extremely satisfying. Concerned about TVI? Go mountaintop portable, or even mobile, for the contest. ICOM also makes the only six-meter portable on the market, the IC-505, with a choice of 3 Watts output using internal batteries or 10 Watts with an external supply. Used with a small car or RV battery, it makes an excellent weekend station, especially with an outboard 100-Watt amplifier such as the Mirage A1015. If the Es is good, go barefoot, and you'll be amazed at what you can hear when the propagation works for you!

More 220

Now I can report to you 220 enthusiasts that there is another way to get more mileage out of your station. For those using the Microwave Modules MMT 220-28 transverter, simply replacing the 96-MHz LO crystal with a 97.5-MHz crystal will yield a conversion of 220–225 MHz down to 25–30 MHz. If you are currently using one of the newer low-band general-coverage radios, you need to enable the set for general-coverage transmit. *Caution:* Don't attempt to run power out of the authorized amateur bands. You will need about 10–50 mW of drive in the range of 25–30 MHz to make the conversion work, and this shouldn't cause any problems in a closed-loop system to the transverter.

I have performed this modification with my MMT 220-28 and am now able to work SSB, CW, and FM (plus repeaters) with one source, running 15+ Watts output. The only catch is that you have to program the repeater inputs and outputs separately, but I use only two or three machines on 220 anyway and this isn't much of a bother. Plus, it yields the popular 223.50 simplex frequency and there's plenty to work here. If you choose not to convert your unit or can't (such as IC-730/740 users, TS-820/830, etc.), then there is at least a way to get on simplex FM by using the crystal switching scheme shown in Fig. 2. This circuit is courtesy of Hans Peters VE3CRU, who is making it standard equipment on all MMT 220-28 units made after March 1, 1986. If you are limited to the 28–30-MHz i-f range, you'll at least have coverage of the 223–225 segment and can work simplex for FM or packet. This frees your HT for other uses and buys superior weak-signal performance on the low end of the band as well.

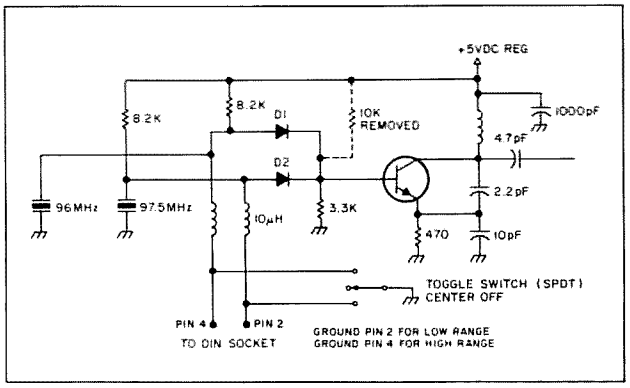

Fig. 2. Schematic of the dual-range modification.

Mailbox

Fred Church WA5YOV writes in to comment on the February, 1986, column statement regarding attenuator pads. He wants to know if using a pad between his Heathkit HW-104 and an MMT 144-28 to drop the drive level from 1 Watt down to about 50 milliwatts would result in less receiver conversion gain going back the other way. Well, first of all, Fred, the typical MMT 144-28 has about 20 dB of conversion gain, which is usually more than adequate for your low-band receiver. If you employ the transceiver connection at 28 MHz and put a pad in the line, your drive level on transmit and conversion level on receive will both be reduced.

Using a 6-dB pad will result in a drive level of 250 mW, which is fine for the MMT 144-28. It will reduce your conversion gain to about 14 dB, which is still plenty for the HW-104. Note what your S-meter readings are when listening to 144 MHz with no pad present and in no-signal condition. I'll bet that your S-meter is sitting at around S1 or even S2. Losing 6 dB of conversion gain will bring it back to about S0, which is where you want it anyway! Remember, this has no effect on the received signal at 144 MHz, although many users seem to be confused on this point. Such an attenuator could be picked up at a flea market or made up from three 150-Ohm, 1/4-Watt, carbon-composition resistors.

Fred's concern is that dropping the drive level inside the HW-104 might affect the linearity of the signal, especially on SSB. This method of cutting the drive shouldn't affect the linearity at all, since the 1 Watt of rf output is looking into a fairly nonreactive 50-Ohm load. Enough of the energy is dissipated by the resistors to bring the drive down to a safe level. And your receiver conversion shouldn't be impaired one bit.

Contest Update

The new rules for the *CQ* Worldwide VHF WPX have been released, which is no surprise to me since I was involved in their formulation. For those readers who took some time off to throw together a portable station and get on during the festivities (or who just operated from their home station from ac mains), here are the details: The date—July 18–20, the format—48-hour contest period, and the allowable bands—50, 70 (Europe), 144, 220, 432, 902, and 1296 MHz. The eight categories of competition stay the same (single/single, single/multi, single/single QRP, single/multi QRP, multi/single, multi/multi, portable, and FM-only). The big difference is that grid squares are now included as the exchange and will replace the serial number from last year.

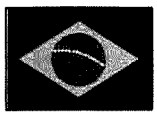
If you don't know or care about your grid square, a location report or signal report will suffice. This information has no effect on the final score, which is still solely determined by prefixes worked. Many stations wrote in to request the grid-square multiplier, so they could continue collecting grids for VUCC on various bands. This is really a fun contest and ties in perfectly with May's column on portable operation, since there are specific classes for QRP and portable competition. I'll certainly be on and hope to work you as well!

Good News

The popular K2RIW 19-element 432-MHz yagis are once again being manufactured after a long layoff and are available from Tom Rutland K3IPW at 1703 Warren Street, New Cumberland PA 17070. This antenna uses exceptional construction, including a soldered driven element. It's priced at $69.95 in kit form plus UPS charges.

Not Again?

I've just received the latest newsletter from the Mt. Airy VHF Radio Club, otherwise known as the PackRats (not to be confused with the AEA product with a similar name!). This club has had a stranglehold on the January VHF Sweepstakes Unlimited class for the past 25 years or better. Why? Because this is an active, involved club whose members travel to all sorts of crazy places to put signals on the air, from 50 MHz right up to 10 GHz! What's more, they really enjoy it, too. I've been to a few meetings and can tell you that this club takes its VHF and UHF activity seriously.



For example, a total of 59 logs were sent in to the club to be posted with the Club Aggregate Score in the Unlimited class. How'd they do? Only about 1.8 million points, that's how! The ARRL ought to change the name of this class to the PackRat Contest Demo class, for theirs is an excellent example of how to organize a large group effort successfully. Others have tried, but the Mt. Airy folks keep plugging along, year after year. Many hams on the East Coast are familiar with their annual VHF conference and flea market which occur the first weekend in October. In addition, the club also runs VHF nets on 50 through 1296 each Monday night, starting at 7:30 p.m. EST. Check-ins come from as far away as North Carolina and Maine! It's a great way to find activity to test out that new piece of gear or to evaluate station improvements.

I'll have a piece down the road on this active radio club. For those who might like more information, the newsletter is very well done and can be had by writing to the editor, Harry Stein W3CL at 2087 Parkdale Avenue, Glenside PA 19117.■

73 INTERNATIONAL

Just because I started this column as a result of visiting DX hams is no reason you shouldn't put in your 2¢ worth and let me know what DX news you find most interesting. My inclination is to have DX ops tell us what they think is interesting—how we can get permission to operate if we're fortunate enough to visit—any coming DXpeditions—what's doing with repeaters—things like that. What do YOU find most interesting? Since we have a world hobby, I think you'll be as interested as I in what is going on. If nothing else, it gives us something to talk about on the air which, from what I'm hearing these days, can't hurt.

—Wayne.

FOR OX MEMBERS

After five years, I visited the city of Fortaleza again. It is located in the State of Ceara northeast of Brazil, and like all Brazilian cities located along the coast, Fortaleza has paradisiacal beaches. Due to its location in South America, it is one of the best places in the world for DXing. So, the PT7 stations are quite active and are always looking for a rare spot on the bands. Most of them are members of a DX club called Fortaleza DX Group (FOR DX), which maintains a special VHF spotting frequency. Every member knows about a DX-pedition or a very wanted station on the air. On this trip, I found DXers like Luc PT7WA, Eli PT7BZ, Pergentino PT7AA, and Freire PT7WZ, old friends I didn't know personally before.

Luc PT7WA (formerly PY7VNY) was one of the first Brazilians to get the 5-band DXCC. He is still very active on the low bands, and is now looking for the 5-band WAZ. Eli PT7BZ and Freire PT7WZ work phone only. Pergentino PT7AA is most active on CW.

Eli's DXCC score is now 292 but he already has the 5-band DXCC and 5-band WAS. Now he is working for the 5-band WAZ and needs only a few zones on 80 meters to finish it. His last interest is the 160-meter band, where he already has 82 confirmed countries. Eli showed us his shack where he displays a few rigs—almost one for each band. PT7BZ confirms all QSOs with his QSL, but if you need a direct QSL you can ask him for it at PO Box 2875, Fortaleza, 60000 CE, Brazil.

CWJF AWARD

Sponsored by the CW Group of Juiz de Fora, the CWJF is available to all licensed amateurs for confirmed contacts with five stations located in the city of Juiz de Fora after January 1, 1985, on any amateur band. Only two-way CW contacts count. The same station may be worked on different bands but with a minimum interval of 24 hours. Send GCR log of stations worked (call, date, time, band, mode, and report) and 10 IRCs to: CWJF Award, PO Box 410, 36100 Juiz de Fora, MG, Brazil.

There are no special endorsements for the CWJF Award.

SWL: Same rules.

CWJF members: PP1AEA (PY4CZ), PU4WAS (PU8), PU4WIG, PU4WLF, PU4XFD, PU4XIA, PY4AG, PY4AKR, PY4ALC, PY4ALV, PY4AMP, PY4EG, PY4EM, PY4CY, PY4QA, PY4QE, PY4QV, PY4RU, PY4YN, PY4ZAX (KA2UFT), and PY4ZF.

de **PY1APS/PY7APS**

NEW BANDS FOR BRAZIL

New radio-amateur services, approved by Decree number 91.836, will take effect on October 12, 1986, allowing Brazilian radio amateurs to operate two of the three new bands, the 18.068–18.168-MHz and the 24.890–24.990-MHz segments, both on a shared basis until January 7, 1989, after which they will be exclusively for radio-amateur operations.

Only Class-A Brazilian operators are allowed to use these new bands, and these are allowed emission types for these bands: N0N, A1A, A1B, A1C, A1D, F1A, F1B, F1C, F1D, A2A, A2B, A2C, A2D, F2A, F2B, F2C, F2D, J2A, J2B, J2C, J2D, A3A, A3B, A3C, A3D, A3E, H3E, J3B, J3C, J3D, J3E, J3F, R3A, R3B, R3C, R3D, R3E, and R3F.

The third band is not yet allowed for radio-amateur use because government safety services and aeronautics services are still using it and there was not enough time to change frequencies and equipment. As soon as these services move to other frequencies, authorities will allow the remaining new band to be used by radio amateurs. We'll pass along the word.

de PY1CC

COSTA RICA

Bengt Hallden TI4BGA
Box 999
3000 Heredia
Costa Rica

73 International welcomes Costa Rica and Senor Hallden, who has been appointed by the directors of the Radio Club de Costa Rica to keep us all informed of amateur-radio events and developments in that country.

Amateur radio in Costa Rica is definitely growing very fast, and licensing is increasing rapidly. HF as well as VHF traffic on the different amateur bands involve more and more Costa Ricans.

The 2-meter band is the most popular, and there are more or less 12 repeaters covering the whole territory, including one channel for autopatch. If you are interested in the different repeaters' frequencies, write the RCCR at TI0RC, Apartado Postal 2412 San Jose 1000, San Jose, Costa Rica.

Regarding licensing proce-

Photo A. PT7BZ's QTH.

Photo B. L to R: PY1APS, PT7AA, PT7BZ, and PT7WA.

dures here in Costa Rica, especially for visiting tourists, it is not very complicated. I would say rather that it's a quick operation as long as all the required documents are in good order. Costa Rica has a reciprocal agreement with the U.S.A. (and Austria, Argentina, Brazil, Venezuela, Chile, Peru, Canada, Mexico, Panama, Switzerland, Belgium, Bolivia, Nicaragua, Ecuador, Belize, Dominican Republic, and the Federal Republic of Germany), thus enabling the tourist to operate from here more or less the same day he arrives.

A must, of course, is the presentation of a valid amateur license when applying for a reciprocal license.

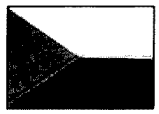
The only exception for the use of your reciprocal license is that it isn't permitted from the Isle of Cocos (TI9). However, if someone should be interested in operating from Cocos Island, arrangements can be made with the RCCR and, if accompanied by some local ham, operation might be possible.

The RCCR has a QSL Bureau with monthly dispatching of QSL cards. Third-party traffic is possible, and special callsigns for prefix hunters are mostly appearing during international contests when TI1 and TE2-TE8 can be heard—also TE1.

Regarding certificates and awards, the RCCR is sponsoring the TTI Award (see below). Any SWL or amateur can obtain this after hearing/contacting seven of the eight call areas of Costa Rica. (The club station, TI0RC, can replace any absent call area.) Send GCR list to me (Sr. Hallden is RCCR treasurer and Diploma Manager) with 10 IRCs or U.S. $5.

The idea of DXpeditions with 20 hams visiting Costa Rica sounds very interesting and, of course, operating possibilities when arriving and during a stay here are guaranteed; in other words, such a group of hams would be very welcome! Just let us know!

The RCCR phone number is 216903, and our office in San Jose is on the central avenue between 1st and 3rd Streets near Hotel La Gran Via. You may call me at 395372, Luis Retana at 220545 or 530393, or Jimmy Vincent at 210012 during office hours.



DIPLOMA FRACAP

The Federation of Radio Amateurs of Central America and Panama (FRACAP) announces a beautiful diploma for radio amateurs and SWLs to raise interest in the member countries of Guatemala, El Salvador, Honduras, Nicaragua, Costa Rica, and Panama.

Requirements are: two-way confirmed contacts after August 16, 1985, any band, any mode, with each of the six countries, with amateurs who are members of a FRACAP radio club.

The application has to be accompanied by the QSL cards or a GCR list verified by the radio club of which the applicant is a member. Applications should be accompanied by 10 IRCs or U.S. $5 and should go to the RCCR Awards Manager at the address above.

73 and Health!

CZECHOSLOVAKIA

Rudolf Karaba (OK3KFO ARC)
Gogol'ova 1882
955 01 Topol'cany
Czechoslovakia

Annually in Czechoslovakia the best individual stations, as well as those of radio clubs in the competitions on shortwave, are being evaluated. For the year 1983, the following results were achieved:

Radio clubs
OK1KRG—75 points (the maximum)
OK1KSO—69 points
OK3KCM—55 points

Individuals
OK2FD—75 points
OK2BHV—63 points
OK1AVD—61 points

RTTY

The operators of radio club OK3KJF made contact with station A92DU from Bahrain island. It was their 109th DXCC list country. They work with the machine T-100 and ground-plane antennas and HB9CV.

Station OK1DNH from Rotava works on RTTY by using a ZX-81. The ZX-81 works without any problems on the lower bands, but on the higher bands it has some problems with RFI.

A very nice placement was achieved by Czechoslovakian stations in the category of multi-operators in the Alexander Volta RTTY Contest 1984. The first three places were occupied by OK3KGI, OK3RMW, and OK3KEF.

UHF/VHF

OK1VRF encountered a signal of station OE5XUM on the frequency of 144.595 MHz on May 11, 1985, at 5 p.m. UTC. The station was located in the mountains near Salzburg as a radio-teleprinter converter, by modulation F1B, shift being 850 Hz, input of 80 Watts.

RTTY transmission has begun for the station of the Central Czechoslovak Radioclub, OK1CRA. The transmission is in the shortwave band as well as through converters in the UHF band.

After two years an experimental marathon SNERA has ended. In this marathon, the Soviet radio-amateur stations were competing to make as many contacts as possible on UHF bands by means of a polar glow.

The category of individuals was won by: UA3BMJ—155 contacts via polar glow for 5,442 points, UR2RQ—139 contacts for 3,795 points, and UA9XQ—149 contacts for 3,159 points.

The category of collective stations was won by radio club UZ9CXM with 23 polar-glow contacts, and the SWL category was won by UA3-142-198 with 9 polar-glow contacts.

Photo D. 73 correspondent Rudy OK3CMZ in Sabratha, 5A-land.

DX

LY4L has a special antenna that was transmitting from Ulianovsk in 1985 on the 112th anniversary of the birthday of V. I. Lenin.

QRP

Igor OK3CUG belongs to the friends of the operation with small inputs, which made 1,300 QRP contacts on the 3.5-MHz band, 840 of which had output of 600 milliwatts. Igor was working with 40 lands according to the DXCC list, the rarest being W1, CT2, UF, and UA9.

Jirka OK1FAO has been working mainly on 3.5 MHz. He used equipment of his own construction with aninput of 2 Watts and made 600 contacts.

The callsign OK1DCP is known from many QRP contests. Franta belongs to the most active operators with QRP in Czechoslovakia. Since 1976 he has made more than 5,300 contacts on the 160- and 20-meter bands. These contacts were made with homemade equipment with an output of 3 to 5 Watts. He has been specializing on the 7-MHz band, operating CW.

Jan OK3ZAP has constructed a homemade CW/SSB transceiver for 3.5 to 21 MHz with an output from 120 milliwatts to 5 Watts. On the 21-MHz band he has worked as many as 55 lands on the DXCC list.

Jarda OK3AUI is a very active QRP operator. With his equipment of 5 Watts input, since 1980 he has made approximately 5,000 contacts, 1,000 of which were on SSB.

Olda OK1DAV works with QRP of his own production with an input of 0.5 to 8 Watts. With wire antennas, operating CW, he worked 50 DXCC lands. In the *CQ* WW DX Contest, he made contacts for the diploma WAC during 12 hours on the 21-MHz band.

Jirka OK1MYN works with QRP on the 14-MHz band with his CW/SSB transceiver with an output of 4 Watts. He worked 74 DXCC lands.

WINNERS OF THE 1984 OK-DX CONTEST (XXVIII)

OGGETTO: RILASCIO DI AUTORIZZAZIONE TEMPORANEA PER L' IMPIANTO E L' ESERCIZIO DI UNA STAZIONE DI RADIOAMATORE IN ITALIA

Il sottoscritto chiede a codesto Ministero di voler rilasciare una concessione temporanea per l' impianto e l' esercizio di una stazione di radioamatore in Italia. Trascrive qui di seguito i dati personali richiesti:

COGNOME e NOME: .....
(surname and name)

DATA di NASCITA: ....
(date of birth) giorno (day) mese (month) anno (year)

LUOGO di NASCITA: .....
(place of birth)

INDIRIZZO PERMANENTE: .....
(home address) .....
.....

NAZIONALITA': .....
(nationality)

NOMINATIVO: .....
(call sign)

SOGGIORNO in ITALIA: dal ..... al .....
(stay in Italy) (from) (to)

INDIRIZZO TEMPORANEO .....
in ITALIA: .....
(temporary address in .....
Italy) .....

INFORMAZIONI SULLA .....
STAZIONE: .....
(informations about .....
the station) .....
.....
.....

Allega alla presente la fotocopia della concessione di radioamatore dello Stato di appartenenza nonché una marca da bollo da Lire 3.000.-

DATA: ..... Firma .....
(date) (signature)

Fig. 1. Application for an Italian temporary license.

Portugal, Spain, Sweden, Switzerland, Turkey, and U.S.A. Application may be made for another three-month permit, however, and up to four consecutive permits may be granted.

Amateurs intending to remain in Italy for more than a year must first register their residence location and then follow procedures established for Italian nationals.

Applications from abroad may be on plain paper, following the format shown in the box. In Italy, revenue-stamped paper (*carta legale* or *carta da bollo*) must be used. Provide the information in Italian.

Enclose 5,800 lira or IRCs of that value (as of January, an IRC had the nominal value of 650 lira) and a photocopy of your station license, which must be valid for the period for which the temporary permit is requested. (For overseas air mail service, enclose an additional 4,700 lira.) Special delivery or registered mail for the application is recommended.

If the application is sent direct to the Reciprocal Licensing Unit (above address), U.S. $10 *in cash* may be sent instead to cover all expenses. An additional U.S. $5 will pay for the permit, and your receipt will make it unnecessary for you to visit the Italian Ministry of P e T to pay that fee. *Remember: checks and postal money orders are NOT acceptable.* It is strongly recommended that permits be obtained before coming to Italy, and that applications be made six to eight weeks in adavnce of your departure.

The callsign you will use in Italy will be your own followed by a slash and the prefix of the Italian call area in which you are operating at that moment.

The Italian licensing administration (to which calls and correspondence should be in Italian) is the Ministero delle Poste e delle Telecomunicazioni, Direzione Centrale dei Servizi Radioelettrici, Divisione 5–Sezione 3, Viale Europa, 160, 1–00100 Roma/Eur Rm, Italy.

Notes on filling out the application: WRITE IN CAPS! (1) Write family name followed by first name and middle name. (2) Write date in numbers. (3) Town, village, and state. (4) Complete home address—as on your amateur license if it is the same. (5) From (in numbers) day/month/year To day/month/year, not to exceed 90 days. (6) Write complete address of the home, hotel, campground, etc., where station will be operated. Note: Mobile service is permitted only on VHF/UHF bands and up, but *do not* specify mobile operations on this form. New regulations are pending. (7) Manufacturer and model of equipment with the rf power (input). For HF bands, input must *not* exceed 300 Watts; for VHF/UHF and up, the input limit is 10 Watts. Specify type(s) of antennas to be used.

CORRECTIONS

An error found its way into VE1VQ's article, "Build a Dynamic Duo," in the February, 1986, issue. The schematic for the cigarette-lighter adapter (formerly Fig. 4) originally showed a short from the base of transistor Q3 to the collector of same. Capacitor C1 (.001 uF) should appear in place of the short. The corrected schematic is shown here in Fig. 1.

In John Coppens' article, "132 Extra Memories For Your FT-107M," published in the March, 1986, issue, transistors T1–T4 should be replaced with BC547s or other suitable NPN transistors.

In the May, 1986, International section, the wrong flag was used with the Republic of China column. *73* regrets the error.

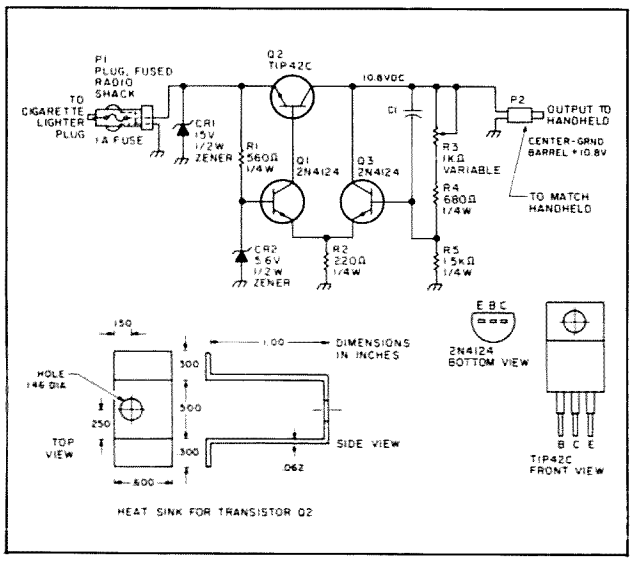

Fig. 1. The corrected cigarette-lighter adapter schematic.

SATELLITES

USING THE AO-10 PREDICTIONS

Apogee predictions for the month of July are provided for three sections of the United States: Washington, D.C.; Denver, Colorado; and Los Angeles, California. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

Ham Awards

Ten American Districts Award

by William V. R. Smith N6MQS

With this issue of *73*, I am pleased to present the first of a series of articles about the many awards available to ham radio operators. Along with information about the rules and requirements of each award, I will present award forms, or worksheets, to help you keep track of your contacts.

Ham awards are presented by clubs and associations to recognize operating achievement. There are many types of awards for all levels of achievement. No matter what your license class, or the amount of time you devote to ham radio, there *is* an award for you.

A Novice can spend a month contacting stations in each of the ten American call districts. A General-class operator tries to work all states during a 48-hour contest.

If you've earned an award, then you know the pride felt when it finally arrives in the mail. If you are working for your first award, just keep working—it's worth the effort!

Many awards have special endorsements. An endorsement is awarded in recognition of a special operating achievement. CW-only, single-band, OSCAR, QRP, RTTY, and SSTV are examples of special achievement. The same award may be earned many times with different endorsements.

When you apply for an award, you must submit proof of contact with the required stations. Proof is most often considered to be valid QSL cards from each of the stations contacted. You may be required to send the QSL cards along with the application. (If you want the cards returned, you must send sufficient postage with your application.)

Some clubs will accept a verified list instead of QSL cards. Each club has its own rules about what constitutes a verified list. Most often a list showing callsign, date, time, mode, and frequency is sufficient, provided it has been checked by two other ham operators or a club official.

A fee is often charged for each award. This covers the cost of printing and the postage to send you the award.

I'll start this series of articles with a relatively easy award: The Ten American Districts Award (TAD), sponsored by the Lockheed E.R.C. Amateur Club (W6LS).

The TAD Award requires contacts with operators in each of the ten U.S. call districts. This award is available to all licensed amateur radio operators and clubs. DX stations are also welcome.

The TAD Award requirements are very broad and are listed below, along with the correct mailing address. With this award, you have a choice of sending your QSL cards or using a verified list. Make a note on the application if you want a special endorsement.

I have created a TAD award for you to use as your verified list. You may use this form even if you send in your QSL cards.

The award fee is very reasonable—one dollar with a verified list or two dollars with QSL cards (to cover return postage). DX stations must add one dollar for the increased postage. Cash, check, IRCs, or U.S. stamps are accepted.

Mail your application, along with payment, by regular mail. The TAD Awards are processed by the 19th day of each month.

73 and I hope to work you on the air. I'll be back next month to feature another award. Good luck with the TAD Award.

Ten American Districts Award Requirements:

- Contacts with all ten American districts must have been made from the same call area.
- Hawaii counts as the 6th call district.
- Alaska counts as the 7th call district.
- Contacts can be made to and/or from fixed, mobile, portable, or fixed-portable stations.
- Crossband and crossmode contacts are allowed.
- If your callsign changes, contacts made using your previous callsign are still valid as long as they are from the same call area. Your present callsign will appear on the award unless you request otherwise.

Mail your application to:

Amateur Radio Station W6LS
2814 Empire Avenue
Burbank CA 91504

GLB TNC2A PACKET CONTROLLER

GLB Electronics - the first commercial producer of packet controllers joins the TAPR Revolution to bring you the GLB Model TNC2A Kit. This kit is the latest TAPR design and is supplied with top quality components. The GLB TNC2A is backed by over 14 years of experience in amateur radio kit products and our technical staff is available to assist you daily from 1 to 3 PM Eastern time.

GLB Model TNC-2A Kit

FEATURES

- AX.25 Version 2.0 Software
- Terminal baud rates - 300,1200, 2400, 4800, 9600
- Multiple connects - up to 10 stations
- Date/time stamping
- Standard DB25 for RS232 connection
- Simple radio hookup
- Radio modem w/built-in counter for calibration
- Low power CMOS option
- Tuning indicator socket for HF & satellite work
- Modem disconnect for future options
- Lithium battery backup for RAM

Hardware
Software
Documentation
by TAPR

Model TNC2A Kit NMOS $154.95
Model TNC2A Kit CMOS $169.95

SPECIFICATIONS

CPU	Z80A microprocessor
Clock	2.4576 Mhz standard, 4.9152 Mhz available
Memory	32K EPROM, 16K RAM standard
HDLC	Packets are controlled by hardware for maximum performance permitting full duplex operation
Modem	1200 baud, Bell 202 compatible (standard) easily configured for 300 baud/200 Hz shift for HF use
Serial	Computer/Terminal port is industry standard RS-232 C compatible for use with most equipment
Radio	Watchdog timer for channel protection transmits audio levels adjustable for nearly any radio. Wide dynamic range demodulator. Channel busy input (RF DCD) to inhibit packet transmissions on a shared channel
LEDs	Power: tells you when power is applied Status: tells you when you have unacknowledged traffic in your buffers Connect: tells you when you are in the error-free mode DCD: tells you when your TNC2A senses other activity on the channel PTT: tells you when your TNC2A keys the transmitter
Power	+ 10 to + 15 VDC (CMOS 110 ma NMOS 250 ma Typical)

Quantity discount schedule

DEALER DIRECTORY

Fontana CA

Complete lines—ICOM, Mirage, KLM, Larsen, Astron, B & W. Over 4000 electronic products for the hobbyist. Also CB and business radios. Serving you from a 6000 sq. ft. store. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Jose CA

Bay Area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1775A S. Winchester Blvd., Campbell CA 95008, 370-6665.**

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors. ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL-COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.**

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

New Castle DE

Factory authorized dealer! Yaesu, ICOM, Ten-Tec, KDK, Kenwood, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off I-95. **Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.**

Derry NH

Serving the ham community with new and used equipment. We stock and service most major lines: AEA, Astron, B&W, Cushcraft, Encomm, Hy-Gain, Hustler, ICOM, Kenwood, KLM, Larsen, Mirage, Mosley; books, rotors, cable and connectors. Business hours Mon.-Sat. 10-5, Thursday 10-9. Closed Sun./Holidays. **Rivendell Electronics, 8 Londonderry Road, Derry NH 03038, 434-5371.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the October '86 issue must be in our hands by August 1st. Mail to *73 Amateur Radio*, WGE Center, Peterborough, NH 03458. ATTN: Hope Currier.

Table of Contents

A Packet Primer
For the totally bewildered—learn the mechanics of packet without having to ask embarrassing questions. W1BEL 28

How To Make Friends At 1200 Baud
Answers the question "What do I do with it?" that you asked after reading the primer. This article explains the operating side of packet W2JUP 34

Precision Packet Tuning
Complete plans for building what could be the world's best packet/RTTY tuning indicator. It's all digital and has a resolution of 10 Hz! . . . WB2OSZ 40

Seeing Packet Radio With Different Eyes
How a blind ham copes with an inherently visual mode. N7FDS 48

So You Want To Be A Sysop?
You may change your mind! Learn the secrets of a successful packet bulletin board station. WB2MNF 50

Birds 'N' Bauds
Amateur satellite builders from three countries discuss what's in store for packet radio in space. NK6K, JA2PKI, DK1YQ, DB2OS, DJ0HC/KE6MN 58

Connect Alarm!
A simple add-on for your TNC that screeches when someone connects to your station. This is a one-hour project (we're timing you!). K7YZZ 66

Survival Training For Mountaintop Digipeaters
The amazing story of a club with a purpose: to blanket the state of California with digipeaters. WB6RAL 68

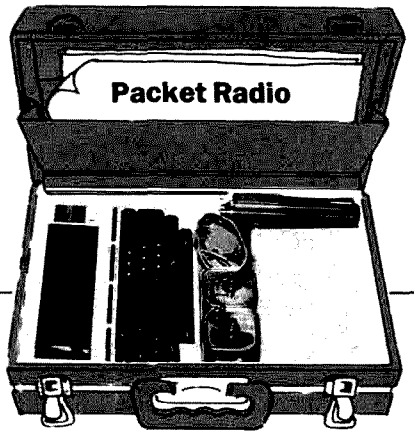
Beyond Level Two
The philosophy of networking and the future of amateur packet radio. Read only after successfully completing pages 1-73. . . . . KA9Q 74

Lightning Never Strikes
These simple precautions can save your rig . . . or your life. W0WUZ 79

And If That Isn't Enough . . .
If you're *still* totally bewildered about packet, join this question-and-answer round table. NK6K 80

On The Shelf
A bibliography of the seminal works in packet radio. NK6K 86

***73*'s Packet Buying Guide**
At-a-glance comparisons of everything on the packet market (complete with prices). . . . . Staff 88



Kit Corner: The DSE 500-MHz Frequency/Period Counter KW1O 90

Reviews

A computer on a drive: Ampro's CP/M Little Board. WA8WTE/4 24
Driving the computer: Hamcom terminal software from AEA. AE5V 26

73 Amateur Radio®

AUGUST 1986 ISSUE #311

Have you heard about packet radio? Probably you have, but you are a bit fuzzy on the subject. Don't bother looking in the other ham rags for help. . . at best you'll find a rehash of some "See Packet Run" article. This magazine is a complete course on a single subject. We've done everything possible to cram every available scrap of information on packet radio into 112 pages: Some monthly columns were omitted, others trimmed down (they'll all be back in September). The result is a series of articles that will take you from knowing nothing about digital communications to pondering the intricacies of system networking.

A Packet Primer 28
We start our packet blowout with a close look at what packet radio actually is, laying the groundwork for the rest of the magazine. This is the nuts-and-bolts stuff, the ACKs and NACKs and frames that make everything work. Here is where you'll find out what a TNC does. (Admit it: You've heard about packet and would like to try it, but you're afraid to ask stupid questions. Well, now you can be Joe Packet without being embarrassed!)

How To Make Friends at 1200 Baud 34
Introducing humans (hams, at least) into a computer-controlled environment can get a bit tricky. W2JUP explores the etiquette of AX.25; what settings to use on your TNC and why. This is the "how-to-do-it" companion to the "how-does-it-work" article . . . you should read them both in one sitting.

Precision Packet Tuning 40
Did you think that there were no construction articles? John Langner's cooked up a tuning indicator for packet (RTTY, if you insist) that you won't believe. This gadget has a resolution of 10–20 Hz, needs no calibration, and lets you dead-eye a signal in about 10 seconds. It's easy to build, too.

Seeing Packet With Different Eyes 48
We've all heard about the effectiveness of RTTY for people with a hearing impairment. But what about the blind? Can packet work for them? Obviously it can, or we wouldn't have an article about it.

So You Want To Be A Sysop? 50
You may decide otherwise! If you *really* have your heart set on a packet bulletin board system, here's all the information you need to get one on the air. Beware: It takes more than a pair of disk drives and a TNC to run a BBS.

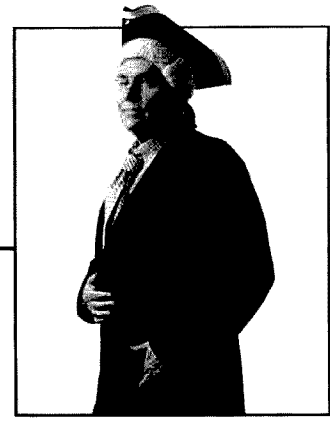
Birds 'N' Bauds 58
An excellent overview of packet radio in space, written by the men who built the satellites. Covered are UoSAT-OSCAR-9 and -11, JAS-1 (scheduled for launch at the end of July), and Phase 3C. (Phase 3C's launch has been delayed due to problems at Arianespace.)

Connect Alarm! 66
Another construction project—this time an audible connect indicator for your TNC-1 or TNC-2. If it takes you more than an hour to build, you should turn in your license.

Survival Training For Mountaintop Digipeaters 68
The true story of a club with a grand vision: To cover the entire state of California (where else?) with digital repeaters. Did it work? If we told you, you wouldn't read the article, would you?

Beyond Level Two 74
Don't turn to this treatise unless you thoroughly understand everything on pages 1–73. The subject is networking and the future of packet radio. Actually, the premise is that networking *is* the future of packet radio. Phil Karn leads you head first into the most controversial topic in ham radio since no-code licensing.

And If That Isn't Enough . . . 80
Just in case you've read this far and are still a bit confused (about packet, that is), take a deep breath and let Harold NK6K fill in the gaps.



We'd like to publicly thank Harold Price NK6K for his work on this project. It is, in fact, Harold's issue: He assembled the authors, enforced the deadlines, and processed the manuscripts before uploading them to our computer. We couldn't have done this without him.—Eds.

"I never want to do this again as long as I live!"—NK6K

Extra copies of this issue are available for $4.50—send a check or money order to *73* Back Issues, WGE Center, Peterborough NH 03458-1194.

Send Canadian changes of address to: *73*, PO Box 1051, Fort Erie, Ontario CANADA L2A 5N8. Return postage guaranteed. For renewals and changes of address, include the address label from your most recent issue of *73*. For gift subscriptions, include your name and address as well as those of gift recipients. For questions concerning your subscription and to place subscription orders, please call us toll free at 1-800-645-9559 between 9 am and 5 pm or write to *73*, Subscription Department, PO Box 931, Farmingdale NY 11737. ***73 Amateur Radio*** (ISSN 0745-080X) is published monthly by WGE Publishing, WGE Center, Peterborough NH 03458-1194. Second class postage paid at Peterborough NH 03458 and at additional mailing offices. Canadian second class mail registration number 9566. Entire contents copyright © 1986, WGE Publishing. All rights reserved. No part of this publication may be reprinted or otherwise reproduced without written permission from the publisher. Microfilm Edition—University Microfilm, Ann Arbor MI 48108. **Postmaster:** Send address changes to *73 Amateur Radio*, Subscription Services, PO Box 931, Farmingdale NY 11737. Nationally distributed by International Circulation Distributors. **Legal Notice:** Your reading this notice is hereby construed as acceptance of a legally binding contract with the publisher of *73*, just as opening the cellophane on a software package binds the buyer to the printed contract therein. Your primary duty as a contractee is to help your fellow *73* readers enforce the FCC regulations. For example, the FCC rules clearly state that it is totally and completely illegal to create intentional interference on our ham bands—right? Okay, your duty is clear. The next time you hear a pileup trying to contact a DX station it is your bound and duty to put a halt to this illegal practice. You don't believe for one instant that every station in that pileup doesn't know full well that he is intentionally interfering with other stations, do you? You *must* stop this chaos—this flagrant violation of the FCC regulations. Leave no DX pileup unturned as you seek your goal of amateur self-policing perfection. Remind them that list operation is within the FCC rules, as long as it is orderly. Once you have the dirty DX situation under control you can start to work on contests. I've several reports of contest stations interfering with each other, despite the FCC rules specifically prohibiting this dastardly activity. Remind these criminals of the penalties for willful violation of the FCC regulations—heavy fines and long prison terms. Perhaps we should petition the FCC to change the rules, making it a punishable offense to have one's call appear on the DX Honor Roll—since there is no way to achieve this disgrace without hundreds of hours of illegal operating. The paper on this page has been specially treated so your fingerprints cannot be removed or smudged, so there is now irrefutable proof of your contractedness. Too bad.

NEVER SAY DIE

WANT TO DESIGN SOMETHING?

Presumably you've been horsing around with amateur radio for a while now. Okay, how much have you learned? Are you the kind of ham who made it courtesy of Dick Bash and hasn't made an effort to learn more? Or have you been working on your theory so you have more than a vague idea of what's going on in your rice box?

What could be simpler than to build a battery charger? Are you up to it, or is something as simple as that a mystery to you? Forsooth! Well, let me whet your imagination by explaining that in fact there is an enormous need for a battery charger. Indeed, if you could put just the right battery charger on the market I think you'd be able to sell millions of 'em.

Now, with that simple clue, can you describe the battery charger I have in mind? That's a test of your inventor's IQ. What kind of battery charger which (as far as I know) isn't available is so desperately needed it might sell in the millions? It's one you yourself have often wished you had.

Tsk, how am I going to make a real ham out of you? How am I going to help you to get rich when you're a lazy thinker? Haven't you any entrepreneurial spirit? Are you really going to spend the entire rest of your life calling in on the same net every night?

You've got NiCd batteries in your HT, right? If you're like me, you've also got 'em in your picocomputer, a portable disk drive, a bunch of toys, a cassette recorder, portable telephone, and so on. I've got a wide variety of NiCd chargers... keep 'em in a box on the closet shelf. But the big problem with NiCds...and I sure hope this isn't news to you...is that they must be completely discharged every now and then so they won't develop a memory and hold only a short charge.

Exercising all my NiCds is not something I tend to remember to do, with the usual result that I often find my HT fading away after a couple hours of work instead of lasting all day. Or I find the low-battery light blinking on my computer. Drat! Now why in hell doesn't someone make a NiCd charger which will do the exercising automatically every few days...maybe in the middle of the night?

Is that something that is technically beyond your competence? Yes, I know NiCds don't drop their voltage very much before suddenly dying, but they do drop enough so you should be able to measure it and come up with an intelligent NiCd charger/recharger. If this is too much for you, perhaps it's time for some serious thought about learning the fundamentals of electricity. It's really about time, isn't it?

Would you enjoy it if I found someone to get started with a course in *73*? Lordy, that could run for years, a chapter a month! If you're not serious about wanting to learn—if you'd rather not bother to know more about electricity and radio, okay. If I take the space—perhaps six pages a month—will you take an hour or so every month to read it and send in your homework?

One of the difficulties with learning electronics is the lack of any good self-teaching texts. Most textbooks are designed to be used as supplements for school classes, so they're more references than self-teaching books. The ARRL *Handbook* is fine as a handbook, but it's a ball-breaker when you try to use it to learn some-

QRX . . .

EDITED BY PERRY DONHAM KW1O

Disclaimer

OUR SHARPER READERS will notice that this issue of *73* is slightly different—we've devoted nearly every page to coverage of packet radio, this month's special topic. What a tough decision! On one hand, we had an entire magazine's worth of great packet articles. On the other, we had all of our regular columns and departments. In the background was the reality that there are only so many pages to put things on. Should we leave out important articles, or leave out the columns? We took a look at what the other ham rags were doing with packet. Pretty wimpy. So, we decided to go for broke (just a figure of speech!) and make this issue a packet instruction manual. Everything that you need to know about packet radio is in this magazine. Next month, all of your favorite departments will return as we take a look at the world below 30 MHz.

Reaching Out

MIKE NEARY, obviously a devout follower of QRX as well as the space program, mailed in the results of the National Space Institute's (now the National Space Society) **Space Outreach '85**. The program solicited ideas from the public as to potential uses of space; suggestions had to be made in 750 words or less. The panel of judges included Walter Boyne, Director of the Smithsonian's National Air and Space Musuem; Evert Clark, Technology Editor of *Business Week*; and former astronaut Michael Collins. Ten ideas were selected for awards, including one from **Patrick Gowen** of Norwich, England, who wants to put a radio beacon on the moon. (Mike Neary: "Personally, I'd rather see a repeater, but I guess you've got to start somewhere!") Other interesting projects in the top ten were an Earth/space television channel (an imaging satellite in a figure-eight orbit around the Earth and the Moon, sending continuous real-time pictures from space), a space ark which would carry the genetic codes of all life on Earth, and a Space Debris Collection System designed to clean up all of the junk floating around in low-Earth orbit. More than 1,000 ideas were presented to the Outreach panel; the collected entries were compiled and presented to the Congress, NASA, and the National Commission on Space.

Youngest YL?

WE HAVE A CLAIM on file for the title, "Youngest Licensed Lady." **Jill Kristine Dietrich KA9VGW** is five years old and recently passed her Novice exam with perfect copy on the Morse test and only one question missed in the written portion. Jill attends kindergarten in Bremen, Indiana. Her father, **Jeff Dietrich WB9ZHV**, says that Jill became interested in ham radio at the age of three, and that she also enjoys riding her bicycle, coloring, camping, playing with the piano, and playing with her three-year-old sister, who also shows an aptitude for the code. Jill's first contact was with KA0WGQ in Flatriver, Missouri, using a Kenwood TS-520S. Are there any challengers to the title? Let QRX know, and be sure to send a picture along.

Compu-Guide

EDITION 3.0 of *The DXer's Guide to Computing* is now available from Radio Sweden International. This is a 35-page manual that covers a wide variety of computer applications in the ham shack, including RTTY, packet, and computer control of receivers. I was really surprised to read that, while 55% of American hams own a computer (the number for *73* readers is close to 70%), *only 23%* of Japanese amateurs own one! (According to a survey taken by Japan's *CQ Ham Radio*.) The book is pretty thorough; you can get a copy by sending U.S. $3 to Radio Sweden International, S-105, 10 Stockholm, Sweden.

CQ Writers

IF YOU SPEAK ENGLISH, you could write for *73*. We are looking for columnists to cover every aspect of ham radio: EME, DXing, ragchewing, antennas (especially antennas!), slow-scan, fast-scan, satellites, or whatever. If you are active on one particular band, be the columnist for that band—we'll have a short column for 80m, 160m, and so on. . . all you have to do is report what's going on on your band. As a columnist, you'll have to send in about five double-spaced typewritten pages every month, plus photos and diagrams. If you want to give it a shot, make up a couple of sample columns and mail them in. If they're lousy we'll tell you they're lousy, but we'll also help you improve them. We also have our readers voting on all of the columns, so if in three or four months you're on the bottom of the heap, you're out of there. Think seriously about giving this a try. We'll pay you a little money—not a lot, but enough to help you buy some toys. Mail your sample columns to Perry Donham KW1O, *73* Magazine, WGE Center, Peterborough NH 03458. Good luck!

Haney Vo-Tech

THE HANEY VOCATIONAL TECHNICAL CENTER is looking for donations of ham equipment, books, and materials for use in a course on amateur radio. It looks as if the school system is allocating no money for the project (typical), so the classes will have to use whatever comes in. **Mike Adams N4EVS**, instructor for the course, points out that any item donated is deductible from your income taxes at the cost of replacement, no matter what the condition of the item is. In fact, Mike suggests that non-working gear would be great for practicing troubleshooting and repair. Once the program gets rolling, a complete ham shack will be set up at the school for the students' use. If you have an item that you would like to donate, drop Mike a postcard stating what you have, the estimated cost of shipping (the school will pick up the tab), and your phone number. Send it to Mike Adams N4EVS, Haney Vocational Technical Center, 3016 Highway 77, Panama City FL 32405.

Is Jill KA9VGW the youngest YL licensed?

Break the Bank

REMEMBER THE CASE of the bugged beads? The company that cracked that caper is back on the trail. . . this time they're after low-lifes who try to break the bank at casinos by using computer technology. **CCS Communication Control, Inc.**, has developed the CD-101 Computer Detector. Pit bosses run wire antennas down their legs and arms, and attach a control unit to their belt. Discreet alarms go off when the unit detects computer hash (I wonder if they get interference from nearby TRS-80s?). The security crew can dress and walk around naturally (or as naturally as they can get with wires running taped to their arms and legs), providing a very low-key guard against compu-cheaters. The price? *Only* $22,000.

Double Eagle

ASTATIC CORPORATION, maker of the famous D-104 microphone, has "confirmed the rumor" that a new mike is in the works. (Actually, the only rumor I heard was in a press release from Astatic.) The new model is the D-204, a scaled-down version of the lollipop that sports an adjustable preprocessor and the same chrome finish as the D-104. The new microphone will be marketed as the Silver Classic.

Lowfing

LOOKING FOR A REAL CHALLENGE? Why not try putting out a signal on 1750 meters? ***The Lowfer Letter***, published by **Hal Murken NQ2Y**, crossed my desk recently, and it looks as though activity on the band is beginning to gear up for the winter season. The 1750-meter band (160–190 kHz) is set aside for low-power stations under Part 15 of the FCC rules and regs; no license is required. There's a limit of one Watt output and a restriction on antennas and feeders (they can't exceed 50 feet), but a look at the list of beacons in the *Letter* indicates that activity on the band is growing. If you're interested, send Hal a few bucks and several SASEs; his address is 19 Hobby Lane, Oakland NJ 07436.

VE Two-Way

VE3CNE, the official ham station of the Canadian National Exhibition, will be on the air from August 13th to September 1st daily from 10 a.m. to 10 p.m. local time. The station is located in the Arts and Crafts Building east of the Dufferin gate, and visitors are encouraged to drop by and operate. Look for **VE3CNE** on the air according to this schedule (time is in UTC): Phone—3.790 at 0200; 7.250 at 1800; 14.180 at 1900; 21.250 at 2000; and 28.550 at 1700. CW—3.710 at 0230; 7.125 at 1830; 14.040 at 1930; 21.150 at 2030; and 28.150 at 1730. This operation is not to be confused with **VE7EXPO**, on the air through October 13th from the World's Fair of Transportation and Communication in Vancouver. VE7EXPO is on practically every amateur band and mode from 160 meters to 1.2 GHz, so you should have no trouble finding them.

The Shootist

THIS FROM JOE MOELL K0OV, via Bill Pasternak WA6ITF of *Westlink*: An armed man apparently in search of a clear television channel shot and killed a CB radio in La Habra, California. According to the police, Dennis Carrico was operating his CB radio when a man with a gun walked in, told Dennis to get out of the way, shot the rig three times, then walked away.

OARS Well

THE OLYMPIA (WA) AMATEUR RADIO SOCIETY is trying to stir up some interest in their **Worked OARS Certificate**. To qualify for this coveted award, OARS members must work 10 other OARS stations, western Washington hams must find 5 OARS stations, and the rest of the world need only work 3 stations. All bands and modes are valid, but there are no special endorsements to the WOARC. You also must mention during the QSO that you are working toward the certificate. Once you've worked your quota, send a 9" x 12" SASE to Certificate, Olympia Amateur Radio Society, PO Box 5582, Lacey WA 98503, along with a log showing the date, time, frequency, and the name of each contacted operator.

World View

STUDENTS AT LESTER PEARSON COLLEGE in Victoria, British Columbia, are getting a taste of the freedom of amateur radio. Pearson is one of five World Colleges sprinkled across the globe whose function is to bring together young people of many different nationalities. Pearson, whose president is *Prince* Charles, has students from 60 countries. The school runs an amateur station (VE7LPC) with equipment donated by the Victoria Kiwanis Club. Pearson has graduates all over the world, including JO1UKS, OA4BIK, C6ADG, PA3BEW, VE7FLP/5Z4, and the husband/wife team of OA4BBU and YV5HFF, who met each other at the club station. VE7LPC is sponsored by Ron Parrett VE7TG.

Thai Ones On

AMATEUR RADIO IN THAILAND is about to become legal. According to **Tony Waltham HS1AMH** of the *Bangkok World News*, ham radio was never really illegal in Thailand, but in the past had been officially sanctioned only for special events such as contests. There was, in effect, an "understanding" with the authorities. The Radio Amateur Society of Thailand has been working for quite some time to get ham activity officially recognized, and RAST officers and members of the government Post and Telegraph Department have worked out a draft of regulations for an amateur service in the country. It has only been a few months since the National Security Council stated that amateur radio is an activity "that is not detrimental to society." Three license classes are called for in the draft regulations, including a no-code VHF license.

Good News, Etc.

THE GOOD NEWS is that the AMSAT Phase-3C spacecraft has successfully completed thermal/vacuum testing at the Martin-Marietta facility in Denver. A few bugs surfaced and were corrected. During the tests, the first JL downlink QSO was conducted by **Rip Ripportella WA2LQQ** and **Karl Meinzer DJ4ZC**. Karl was on mode L (24 cm up, 436 MHz down), while Rip used mode J (2 meters up, 436 MHz down); the uplink frequencies were chosen to produce an identical downlink frequency. The bad news is the recent failure of the European Space Agency's Ariane-2 booster, the fourth failure in 18 launches. Phase-3C is scheduled to ride the maiden flight of the Ariane-4 rocket in November, but Arianespace has suspended all operations until an investigation of the Ariane-2 failure is complete. The rocket was detonated after its third stage failed to ignite, destroying the $55 million Intelsat V satellite on board. This catastrophe comes on the heels of the ill-fated space shuttle launch in January, the explosion of a Titan booster in April, and the crash of a NASA Delta rocket in May. The western world is basically without access to space. (A recent editorial on National Public Radio's *All Things Considered* suggested that we ask the Soviets, with their 90% efficiency record, to launch our satellites for us.) It now looks as though Phase-3C will be delayed until 1987.

Meanwhile. . .

ALL IS NOT SO GLUM on the satellite scene. By the time you read this, the first Japanese-built amateur bird, JAS-1, should be off the ground and into orbit. The launch is scheduled for 2030 UTC on July 31st. Information about the digital side of both JAS-1 and Phase-3C can be found in this month's article, "Birds 'N' Bauds," on page 58. (There's a story behind that title which deals with a bar in Dayton, Ohio, called "Lips 'N' Sips," but we'll save that tale for another time.)

Thanks

ANOTHER MONTH OF QRX comes to an end. I'd like to thank everyone who makes this column possible, especially Tony Waltham HS1AMH, Roy Parrett VE7TG, Jeff Dietrich WB9ZHV, Dona Wolfe N7HOE, Bill Pasternak WA6ITF and *Westlink*, Thelma Woodhouse VE3CLT, Larry Reid VE7LR, Hal Murken NQ2Y, Mike Adams N4EVS, Mike Neary, *Sweden Calling DXers*, and *Amateur Satellite Report*. Send your news items and photos to QRX, *73* Magazine, WGE Center, Peterborough NH 03458, and we'll do our best to get 'em in.

NEVER SAY DIE

from page 4

thing. It is better used for reference than for teaching.

If I don't hear from you about this I'll have your number.

Now, back to the NiCd exerciser—let's get to work and see who can come up with the most elegant design. It should be able to handle any given voltage. My NiCd chargers are in 3-V, 5-V, 6-V, 8.5-V, 12-V, and 25-V sizes. The 25-V charger is for a portable printer. Naturally I took the damned printer with me on a trip to Asia, but managed to forget the doubledamned charger. I shopped Akihabera in Tokyo from one end to the other looking for a 25-V charger. None at any price! And wouldn't you know the manufacturer used a small rocker switch on the printer which of course turned itself on in my suitcase so it arrived in Tokyo completely discharged. Phooey.

Let's see what you can come up with to sense when NiCds need to be recharged—then to completely discharge and recharge them. There should be some indication on the charger as to where you are in the cycle. Have you ever seen a NiCd charger which gave you the slightest hint as to how charged you are? That's ridiculous!

Now look here, you've been putting up with this NiCd nonsense as long as I have and you haven't made a move to do anything about it. How many of you dutifully discharge your NiCd packs every few days? How many of you keep a timer by your charger so you'll not overcharge? I don't even recall ever seeing a NiCd charger with a timer built in—and these damned things don't do at all well when trickle-charged.

You say that building a voltage-sensing chip into a charger is beyond you? That even building a timer chip has you in a panic? Say, we've got to get you going with some simple building projects and get your ham juices running. Back when we used to have lots of kids coming into the hobby, most of 'em weren't fazed by little things like that. Naturally, now that we have a geriatric hobby, we can't expect old people to be able to actually learn anything. Old brains are so totally frozen with bad habits that they're unable to learn even the simplest of new things... right? You can't teach an old dog new tricks you're telling me, right? Pant, pant.

The next time you're in a bookstore check the animal stacks and take home a Barbara Woodhouse book on training old dogs. It turns out they're not much more difficult to train than young ones. Just because you've spent the last few years avoiding the technical articles in the ham magazines doesn't mean you can't learn. It does mean you'll have to make do with less Tom Selleck and those brain-damaging sitcoms we use to keep our children stupid.

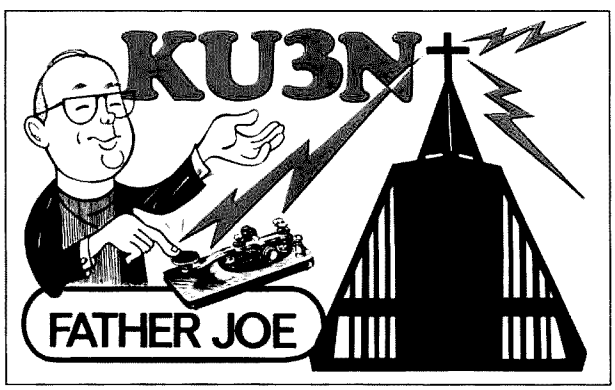
Speaking of children, the chances are that unless you've been working DX every night, you have some around the house. Take a check and see. Even if you've been DXing, the liklihood is that your wife hasn't, so there should be some kids around, even if they aren't yours. Ask about it when you get through reading this.

Let's see, with the average ham age now at 56 and rising, your kids must be around 34 or so. Hey, that means they probably have kids around 12—just the right age for exposure to amateur radio. If you do it right the infection will last a lifetime. It's incurable when properly set. I don't know your infallible system for spreading our common infection, but one I've found remarkably effective is the use of negative psychology. "Don't ever let me see you anywhere near Grandpa's ham rig." That's all it usually takes to create a situation they can't resist. Let me know what works for you.

If I got you thinking on the NiCd exerciser/charger, you may start looking for more gadgets to whip up. One thing we've been needing for years is a simple automatic ID system for our rigs. Yes, I know about the Morse-code ID we use with repeaters. I haven't run into anyone using one of those on his own rig. I don't expect to. If you run it slow enough so people can copy it, it's a nuisance. If you run it fast, no one can copy it.

Okay, you inventor-oriented readers should already have the new ID system almost designed. My approach would be to use a computer—probably a C-64, since there are so many of 'em and they're el cheapo if you don't have one yet. I'd then set up a 9600-baud clock and have the ID unit send out the code. Let's see, we'll need a protocol for this... need to come up with a format.

At 9600 baud how long will it take to send a six-character ham call... maybe eight if it's a portable... plus two for the state and two for counties? If you can't figure that out you're indeed in trouble. Using ASCII we have eleven bits per character... a start bit, eight for the character, one stop bit, and one for parity checking. So we need to send 132 bits. At 9600 baud... where bauds are bits per second... we'd be able to get that through the pipe in 14 milliseconds. That's just over a hundreth of a second. Heck, that shouldn't eat into our talking time too badly. Yes, I know there are some old-timers who don't even leave that much time between drawls.



If our rigs were set so they'd send hundredth-second ID bursts, we'd be able to call CQ with these miniscule bleeps. We might even be able to type in the call letters of the station we're calling and send a double bleep, getting the establishment of a contact down to a 30th of a second.

The next step is obvious. Just think back twenty years to 99% of the contacts you've made. You've been saying exactly the same thing almost word for word for years. I know you have because I've been listening to you. I've heard you tell the other chap what rig you're using. Thirty seconds later he's forgotten, if he ever heard you in the first place. He also could care less what antenna you're using.

If he really wanted to know your name and QTH, he could look it up in his *Callbook*. So when it comes down to it, the only remnant of a contact a day or two later is the call letters. Signal reports? Come ON now! Just put down a 59 and forget it. The next time I print up some logs I think I'll just fill in the report column with 59s and leave a small extra column for dB over S9. That's the baloney column.

So if all we need from a contact is the call letters, we're moving right along. The next move is to get your rig to automatically find a clear channel and start sending periodic call bleeps. When the autotune receiver of another operator comes to your bleep, it'll respond with its call bleep... and you've got a contact once you acknowledge his call. Your printer should print out the QSL card for you on a continuous QSL form which you can tear off every day or so and send off to the bureau.

Your computer will log all the contacts, keeping track of counties, zip codes, states, ARRL countries, IARU countries, *CQ* zones, and ITU zones worked—printing out daily, weekly, monthly, yearly, and cumulative scores. You might want it to keep track of your fastest worked-all-continents time, too. Can we get that down

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, WGE Center, 70 Rte. 202 N., Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

under one second without planning it ahead?

Your receiver can tune for the ID bleeps and show you the call on its screen. You can easily program it to call only specific prefixes. Hey, here's your chance to be the first ham to work one hundred countries in alphabetical order! It'll make checking for DXpeditions a snap. It might even make DXpeditions simple since the operator would no longer have to actually be there. You could just send the rig in a box—have someone put up a dipole, plug it in and turn it on. Low-life DXers might set their DXpedition rig up so only they could contact it. I know a DXer who fits that description perfectly... right, Frank? Are you still pulling those bogus rare DX cards out of your coat pocket at hamfests and club meetings?

The nice thing about this is we'll be able to get rid of the pileups. That'll be a disappointment to the 10-kilowatt crowd, those who get more joy from squashing dozens of DXers than from the contacts they make. By the way, chaps, pileups are absolutely illegal and you know it. I don't want to ever hear you sanctimoniously talking to anyone about rules and regulations if you ever get into a pileup.

You know the ham rules as well as I and it's illegal to create intentional interference. Is there any other name for plonking your signal on top of someone else calling a DX station? You know damned well there are others on the frequency, so you know full well you are as illegal as all hell. You know you are breaking the law... that you are thusly a creep and a scuzzball... unless I get the contact.

There's another invention for you. You sharp inventors have already figured out what I'm going to suggest. Let's see a circuit which detects a pileup on frequency and sends 1,000 volts at high amperage through the microphone to a steel plate in the operating chair if the transmit button is pushed. We'll get those pileups down to manageable size for me yet.

I don't know if 1,000 volts is enough. Maybe you can recommend some DX ops who should be recruited to check out the optimum voltage. It'd make a good article for *73*, right?

NEXT: MADE IN KOREA?

How long before we start seeing some ham gear made in Korea? With the plummeting of the dollar vs. the yen, the Japanese are busy moving production to Korea. You see, the Korean won is tied to the dollar, not the yen.

The Koreans are already busy flooding the U.S. with color TV sets and VCRs. Look for more and more consumer electronics to come from there... mainly from the two giant Korean firms, Samsung and Gold Star. Both of them are already in production on 8mm cameras and VCRs, so they're not seriously lagging in technology... which they've been buying from Japan, there being very few Korean engineers or technicians.

Being so close to Japan, the Koreans have been hiring Japanese engineers and technicians to fly over on weekends to moonlight. The Koreans, by not encouraging amateur radio for youngsters in Korea, have gotten themselves in the same fix we have... they haven't the needed technical people. They're fortunate to have Japan close by so they can import the needed talent on weekends... we're too far away, so we're just plain up the creek.

If Japan isn't careful they could end up losing all of the consumer electronic industries to Korea... and with them would go the whole supporting infrastructure of parts manufacturing. Indeed, this has been rapidly moving to Korea, too. You know, even if we could scrape enough engineers and technicians together to get consumer electronics manufacturing going in the U.S., we no longer have the parts we'd need... the resistors, capacitors, transformers, coils, circuit boards, and so on. Most of the firms making those went the same way our American manufacturers did... pffft.

No, we don't have amateur radio to blame totally for this debacle. The American tax structure did its part to destroy investment here, too. When I was interested in building a product to sell in Europe I priced making it here and shipping it over vs. making it there. I found that if I wanted to invest $250,000 in a plant here to make the product I'd first have to earn a second $250,000 and give that to the IRS in taxes. If I wanted to set up exactly the same plant in Ireland I found I'd only have to send over $125,000. Ireland would then match it... help me find a good manufacturing site... and pay to train workers or even pay to send them to the U.S. for training. The bottom line was that I'd get four times the bang for my buck by opening a plant in Europe ...plus I'd have further tax advantages from manufacturing in a Common Market country... and a tax holiday for several years in Ireland. You can see how our tax situation drove a large part of our manufacturing out of the country. I formed an Irish branch of my company, just as did Apple, Memorex, and many other U.S. firms. It's the people who write dumb tax laws who are the problem, not the businessmen who prefer to avoid them.

Smaller firms aren't equipped to handle an overseas branch, so they either make a go of it in spite of the tax situation... or don't. Our shortage of engineers and technicians has hurt this group the most, virtually eliminating them as competition.

This is not a new situation. Over ten years ago, when FM and repeaters were just getting up steam, Standard Radio was our largest ham gear supplier. They made HTs, mobile FM rigs, and even repeaters. Indeed, it was a Standard repeater I took over to Amman and set up as JY73 back in 1973 on .34/.94.

When I visited the Standard sales offices in Los Angeles I found the service department was made up almost entirely of Japanese hams. They'd given up on finding American technicians, so they'd had to bring Japanese hams over.

I've tried to interest the Koreans in using amateur radio as a way to develop more of their desperately needed engineers and technicians, but the political situation there is a difficult one. Perhaps, if we're able to get enough hams for a DXpedition to Seoul in October, we'll be able to get 'em more interested in developing more Korean amateurs.

If you do go on the trip I think you'll have an opportunity to see one of the most modern, highly automated electronic factories in the world. We'll see if they start getting into making ham gear as well as other consumer electronic equipment... and cars.

BETTER HAMFESTS

Perhaps there is a need for a hamfest organizer's newsletter. I see innovative hamfest ideas here and there, but on the other hand I see some hamfests which sure could use major consulting from an expert. Having probably been to more hamfests than any other living ham, I'll get the ball rolling here with some ideas. Lordy, I've been to hamfests all around the world! Here are some random thoughts you might pass along to your next hamfest committee:

There are four general groups you want to attract and each requires a different pitch. First come the industry people for the exhibit area. Second are the flea marketers. Third are the local hams. Fourth are the hams from up to about 200 miles outside the local area.

The industry people who are most important to you are the ham dealers. Of secondary importance are manufacturers, which includes the magazines. You'll increase the industry exhibits by emphasizing the quantity and quality of the attendance... but don't be tempted to exaggerate it... most of us have been to enough hamfests to be able to make surprisingly accurate estimates. You have to let industry people know a year ahead so they can set their plans. And please, don't have your hamfest conflict with another major hamfest!

Since most industry people come from afar, be sure to let them know about any nearby attractions such as theme parks. You might also make up a special map showing the location of restaurants and shopping areas ...perhaps with some recommendations. This will help out-of-town ham visitors too.

You might arrange for an exhibitor meeting on Friday night. Provide a meeting room and refreshments. Also, even if you have to increase the booth price a bit, consider having an exhibitor lounge with some coffee and snacks in the morning and sandwiches for lunch so they don't have to get on the chow lines and waste valuable sales time to get food. Coffee and doughnuts in the a.m. are greatly appreciated. Dayton has a separate exhibitor's lounge. Orlando and Miami provided nice exhibitor lunches.

You might include brochures for local attractions in your mailings. That might get out-of-town industry people to bring their families and come a day early or stay a day late—and help bring 'em back again next year.

Have you thought to have someone go around to take pic-

LETTERS

OPEN REPLY

Richard Baldwin W1RU
President, IARU

I have read with great interest and considerable dismay the "open letter" addressed to you by Herbert Schoenbaum KV4FZ published in the May, 1986, issue of *73* Magazine. As Net Control for the Caribbean Maritime Mobile Net (7082.5 kHz, 1100 UTC to 1200 UTC daily), I feel I must take considerable exception to KV4FZ's across-the-board condemnation of cruising yachtsmen who are also hams.

Mr. Schoenbaum is completely in error that "cruisers" do not feel it necessary to obtain reciprocal licenses in foreign ports. In my experience, the vast majority do obtain such licenses, and are well aware of the necessity for doing so. We have files of information available to facilitate this licensing, and are frequently asked for it. Certainly, there is a small minority [of yachtsmen] who do not accept the concept and operate illegally. These are soon eliminated from our net operations, if there is any question at all. I just wonder how Mr. Schoenbaum obtains his alleged information on these so-called "illegals" or "pirates." He currently resides in Ohio!

Further, if a cruising yacht obtains a C6A reciprocal or any other and takes a few days' cruise away from that jurisdiction or waters, then returns, it is certainly not only legal, but required that he use his U.S. callsign aboard his U.S. registered or documented vessel while in international waters. On his return to the port where his reciprocal license was issued, he must again, of course, use that callsign designation. A case in point—the British Virgin Islands are only 40 miles from St. Croix. Boats going to the BVI use their U.S. callsigns en route, then obtain a BVI VP2V reciprocal on arrival and use it in BVI waters. They can cross over and back many times, using their U.S. call en route and their VP2V recip. while in BVI territory. That recip. is good for one year, whether in BVI waters or not.

Mr. Schoenbaum's allegations that cruising yachtsmen only use their ham radio to make phone patches is ridiculous. I have managed my net for about two years, taking up to 30 daily check-ins, and doubt if I've been asked to make over a dozen patches in that time! Those who do ask for and make patches are usually in areas where there is no phone service, or it is poor at best.

And his contention that "cruisers" seldom get on the air on the high seas in true international waters is a complete falsehood. I cannot count the number of "Maritime Mobiles" I've passed traffic for and given weather information, port information, etc., to, who are en route from the Azores, Canaries, or from here to Bermuda, the Panama Canal, etc. Further, a large part of our "cruisers" seldom get on their radios in port, as, rather than "luxuriating" in a foreign marina being entertained, they are too darned busy working on their boats and, yes, even working at jobs. Mr. Schoenbaum seems to feel that all yachtsmen are wealthy idlers, and this perhaps has led him to zero in on them from pure envy of their lifestyle!

I have met personally many, many of these folks, and have found them all fully aware of, and accepting of, the legalities of the use of ham radio aboard their boats and in foreign ports. A large portion were hams long before going sailing.

We provide a service, the name of the game in amateur radio, and have been directly responsible for saving lives and property, locating overdue or missing vessels, providing local navigation information, and so on.

KV4FZ, whom I've known personally for about 10 years, is an extremely knowledgeable electronics expert. I seriously doubt he has ever set foot on a blue-water cruising yacht for a real cruise. Therefore, I feel he should confine his expertise to electronics and refrain from his Quixotic zeal in chasing "pirates" and interfering with the operations of the various Maritime Mobile Nets!

Louis K. Bean KV4JC
St. Croix USVI

I'm really tired of hearing the constant bickering between KV4FZ and the Maritime Mobile Net. It's been in and out of the ham magazines for years—always the same accusations, always the same indignation. You want trouble? Let's talk about the taxi drivers in New York using two meters. Let's talk about the contras *in South America running around with their IC-02ATs. Who cares if a couple of yachtsmen use 20 meters for phone patches? At least they're hams.*

There are more important things to worry about than whether a ham is where he says he is. You guys seem to forget that ham radio is a hobby, *not a religion. Until someone comes up with something intelligent to say, you'll not see another word on the subject in* 73.*—KW1O.*

DIGITALIS

I like the proposal for a digital-radio service. Ideally this should be part of ham radio, but it can never be due to the emotional issue of Morse code. If this service had been available three years ago, I would have never gotten a ham ticket.

Earl Morris N8ERO
Midland MI

That's exactly what the opponents of the Public Digital Radio Service are saying. Although amateur packet radio and the PDRS are fundamentally different, most people would flock to the "no-code" PDRS, leaving ham radio in the lurch.

Believe it or not, we have another shot at a no-code amateur license. It looks as though the Novice Enhancement proposal will be approved—once it is in place, we'll put on the pressure to drop the 5-wpm code requirement from the Novice license.

No-code is far from dead—the FCC is in favor of it, the ham manufacturers are in favor of it, and you and I are in favor of it. The crucial missing piece is the Board of the ARRL, and I have the feeling that with sufficient pressure from the membership of the League, the Board would endorse a no-code license. Remember, Earl, that ARRL Directors are basically politicians, and politicians have been known to change their minds.—KW1O.

TECHNOFLUBS

My career is electronics, for which I have always had a spiritual love. I owe most of my success to ham radio; electronics education in America is disgraceful! My high school friends and I started an informal club to teach ourselves electronics (in the late 50s) because there was no other way to learn it.

We were denied permission for a ham station at school. The attitude there seemed to be, "We, the intellectual elite, don't understand electronics; therefore, it is irrelevant." We were reduced to conspiracy—having gotten the runaround after requesting nicely that the school library subscribe to *Popular Electronics*, we mailed a subscription form in the school's name, checking the squares marked 5 YEARS and BILL ME LATER. It worked!

It's impossible to learn anything in the public school system that leads to occupations better than teaching. If teachers knew such things as electronics, they could get real jobs! The back half of my high school physics book was filled with good electronic stuff, but the teacher never reached it.

I expected to learn "real" electronics at a state university's engineering school, and was badly disillusioned by a faculty of frustrated physicists and mathematicians with no practical experience. Several of them could not speak understandable English. The prevailing educational theory there was, "If you know all of the generalities, you can derive all of the specifics." More academic elitism! Though I managed to graduate, I feel that most of my time was wasted. The most useful knowledge I gained in college came from ham radio, through association with the university's club station.

Professional educators apparently still espouse the effete and fraudulent theory that a teacher doesn't need to know the subject matter, but only how to teach. My city has a fair amount of electronics industry—a local high school grudgingly offered a basic electronics course, employing a teacher who attempted to explain the "shematic" diagram of a "superheat" receiver.

There are still a few excellent technical institutes staffed by real electronics people instead of "educators." Is the dwindling number of young hams any surprise, when high school students are advised by teachers and peers that a technical education isn't a "real" education, and that engineering is bad because engineers design

weapons? Does Japan have such a problem?

Name withheld

I spent a year in the Electrical Engineering department of a large eastern university, and was sickened to see senior EE students who couldn't tell the difference between a capacitor and a resistor. They could solve equations and even design circuits using resistance and capacitance, but they had no practical experience at all. One day, I stood quietly and watched while two graduate students attempted to solder a transistor to a printed-circuit board—without solder! They were trying to melt the leads.

I'll bet that in Japan things are not much different. I realize that every child in Japan is taught electronics in school, and I recognize the preeminence the country has in the electronics industry. In America, every child is taught mathematics in school. Are we a country brimming with mathematicians? Of course not.

Two things account for Japan's success in the electronics industry. First, the Japanese are extremely good at copying other people's technology. Second, the Japanese government and the industry work side by side to make certain that they remain on top of the heap. The result is that electronic products are made with a higher quality and a lower price than we can ever hope to achieve. Improving our technical education is useless unless we can also bring production costs down to a reasonable level.

It's crazy to buy American products just because they're American; I refuse to pay twice as much for a product half as good as what I can get from overseas.

By the way, why did you want your name withheld? Are you still hiding from your high school librarian?—KW1O.

10 METERS OR 11?

The recent tragedy on Mt. Hood, where nine teenagers lost their lives, prompted some thoughts on how ham clubs could help to prevent such occurrences. Not by providing emergency communications after the fact, which is done now, but rather to interest climbing club members, who are mostly young people, in getting ham licenses so that they would always have communications with them during their climbs.

There are a number of occurrences of lost hikers and climbers each year in the Pacific Northwest, and I am sure that it happens throughout the country. These events cost a substantial amount of money in terms of rescue activity, to say nothing of the risks taken by rescue personnel.

It seems to me that it would be an excellent project for a ham club to acquaint climbing and hiking clubs with the wonders of having amateur radio with them on excursions to the wilderness. There may be thousands of new, young recruits for the ham ranks to boot.

The main activity, as I see it, would be to tell climbing clubs about VHF and repeaters, and the natural combination of mountain-climbing and ham radio. The emergency aspect is a bonus. Could this be another incentive for no-code exams in the VHF and UHF bands?

I am challenging a local club to start something along these lines and I would request, since you have been prodding clubs to get going on new recruits, that you could make a similar challenge on a national scale. How about it?

Niel Classon W7NYB
Renton WA

I hate to say it, but you would be better off telling the clubs about CB. Their public-service record is just as good as ours, and there are about ten times as many CBers as there are hams. There's even a national CB emergency channel, something we hams haven't thought of.—KW1O.

AM-ATEUR RADIO

One of the main reasons that yours and other fast-buck ham magazines ignore AM is that there is *no money* in it for you—no big, glossy ads. You cater to the bucks, and the Japs have them.

Heaven forbid! If too many hams started using AM, it would cut down on your business. After all, most AMers are running old junkers 25–30 years old. That's not the worst of it: Supposing, horror of horrors, that new hams and others started building AM transmitters from old black-and-white tube-type TV sets. It would be disastrous—for your business, that is.

So please, spare us all that crapola about the state of the art. AM phone is still an efficient and effective means of communication. We know you are mainly out for the payola.

Fred Huntley W6RNC
Nevada City CA

What, you mean there's money to be made in ham radio? Get with it, Fred, AM is about as efficient as spark. I suppose when CW came around, there were still a few spark-forever fanatics who clung on to the very end, and that's the way it will be for AM.

If AM is so hot, why isn't anyone writing about it? We don't toss AM articles into the garbage; we don't get any AM articles. The reason is that ham radio has moved on. . . if you're stuck in the hobby of 40 years ago, I feel sorry for you.—KW1O.

LEND ME UR EAR

Your editorial about the proposed Electronic Communications Privacy Act (ECPA) was to the point, as usual, but didn't tell your readers what to do about it. Calling your Congressman's office and just leaving your opinion with a receptionist doesn't help. You have to get through to the decision-makers.

I called my legislators and asked to speak with the staff member responsible for communications issues. These staffers are responsible for reviewing pending legislation and often determine how a legislator votes on an issue.

In speaking with these staffers, I found that none had read the bill, and only one had a vague idea what it was about! After explaining what the bill was (I had called a Senator in January to ask for a copy of the proposal, which I promptly received), I ran through my list of objections. All three staffers seemed interested in my objections. Letters were sent to the three reiterating my conclusions. I tried to be as logical and objective as possible—emotional pleas just won't work. Representative Judd Gregg seems to have changed his position, and Senator Gordon Humphrey appears now to understand the issues.

I'll bet that my communications about ECPA are the only ones received by these legislators. As such, they will carry a lot of weight. The key is to effectively communicate with the decision-makers in government. You must speak with the proper staff member and follow up your conversation with a letter. We can have a large say in legislation if we just influence the right people.

Peter M. Bealo WB2MJG/1
Salem NH

SUB CW

While I was reading Never Say Die in the April issue of *73*, I was somewhat surprised, or should I say impressed, to learn that Wayne does scuba diving. I have been diving for only five years, but have enjoyed amateur radio for more than 30 years. I hold an Extra-class ticket and a Master Diver Trainer (instructor) certification.

As a diving instructor, I offer a specialty diving course entitled Underwater Communications Using International Morse Code. In the course I teach CW up to five wpm and the different ways to use CW underwater, and I encourage my students to go on for their Novice license (the course material includes a ham license manual).

The marriage of diving and amateur radio is becoming very popular with the course members. It is drawing the divers into ham radio and the amateurs into diving.

A side benefit to all of this is that when I take a group of divers to the Caribbean each summer, I have a ready-made group of hams to make a mini-DXpedition. As you well know, what could be more exciting than a dive trip and DXpedition to some exotic island? This kind of excitement is most appealing to the age group the diving industry is trying to attract—the age group that amateur radio needs.

This may be a small contribution to make to solve the problems confronting amateur radio and its lack of growth, but for the past year the local radio club and Novice class has produced no new hams. During this same time period my classes are getting the attention from the would-be hams.

There are all kinds of possibilities for the future, maybe an international club of some kind for amateurs who are also active divers to promote diving trips and DXpeditions. Maybe a net to discuss different diving activities; the next best thing to diving is a good ragchew about diving!

Bill Wheeler K0DEW
Lebanon MO

NEW PRODUCTS

AEA PK-232 MULTIMODE CONTROLLER

The Pakratt™ model PK-232 multimode controller is now available from Advanced Electronic Applications. The PK-232 is a complete Morse/RTTY/ASCII/AMTOR/packet terminal unit which interfaces with any computer having an RS-232 port.

A front-panel switch allows selection of one of two radios for easy HF/VHF selection, and a discriminator-style tuning indicator is included. Twenty-one indicators monitor mode and status.

The PK-232 retails for $319, and will be available August 1st. For complete specifications, please contact *AEA, PO Box C-2160, Lynwood WA 98036-0918.* Reader Service number 163.

YAESU FT-767GX

Yaesu USA has introduced the FT-767GX HF/VHF/UHF multimode transceiver. The FT-767GX comes equipped for HF operation, and optional modules are available to extend coverage to 6m, 2m, and 70 cm. The rig outputs 100 Watts on CW, SSB, AM, FM, and FSK.

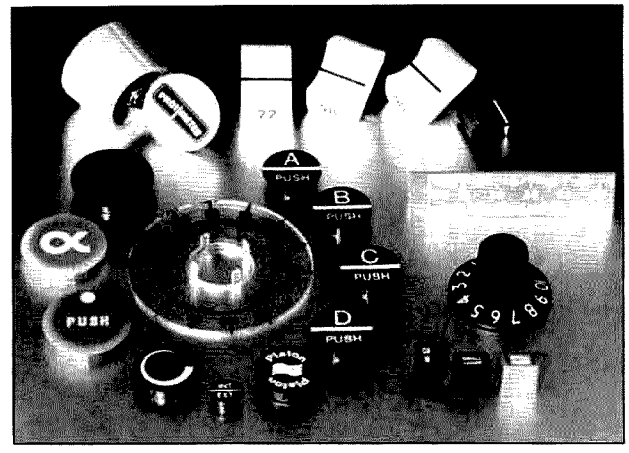
Factory-installed features include an automatic antenna tuner for 160–10 meters, a CW filter, an electronic keyer, a speech processor, a digital wattmeter/swr meter, and a dual-vfo tracking system for OSCAR or repeater operation.

The FT-767GX is priced at $1,759.95; modules for 2m and 6m are $169.95. For complete specifications, contact *Yaesu USA, PO Box 49, Paramount CA 90723-0049.* Reader Service number 152.

CUSTOM KNOBS

Custom-printed knobs and dials are available from Selco Products. Virtually any logo, numeral, symbol, or line can be printed with a character height of as little as 1mm. A wide variety of shapes can be printed on, and it is possible to print lines around a corner. Knobs and dials come in black, gray, white, and clear, and can be overprinted in a variety of colors.

For more details and samples, contact *Selco Products Co., 7580 Stage Road, Buena Park CA 90621.* Reader Service number 153.



NEW MERCER DMM

Mercer Electronics, a division of Simpson, has introduced the model 9370 autoranging digital multimeter. The 9370 measures up to 1,000 V dc in 5 ranges, up to 750 V ac in 4 ranges, up to 10 Amps in 2 ranges, and up to 2 megohms. A memory mode stores a zero offset of 99 counts. Also included is an audible continuity tester.

The model 9730 retails for $59. For more information on the entire line of Mercer test equipment, contact *Mercer Electronics, 859 Dundee Ave., Elgin IL 60120; (312)-697-2265.* Reader Service number 158.

ICOM IC-48A

The IC-48A 440-MHz compact mobile transceiver is now available from ICOM America. The IC-48A covers 440–450 MHz with an output of 25 Watts. Features include a large LCD with auto-dimmer, and 21 scannable memory channels. For more information, please contact *ICOM America, Inc., PO Box C-90029, Bellevue WA 98009-9029.*

Custom printing services available from Selco.

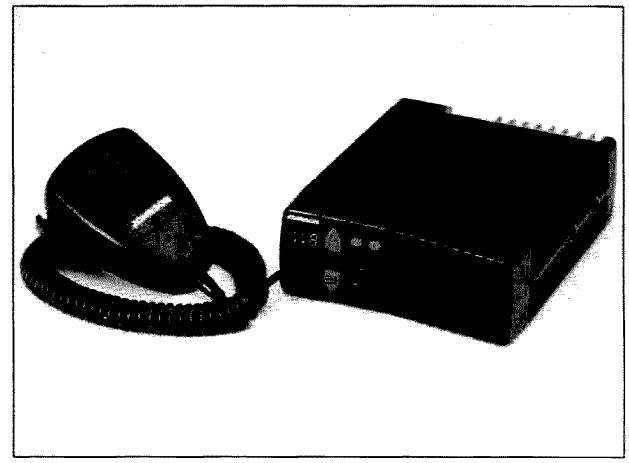
JOHNSON CHALLENGERS

The E.F. Johnson Company has introduced a new series of VHF/UHF mobile radios. The Challenger™ UHF mobile (15 Watts) and VHF mobile (20 Watts) come with eight synthesized channels and programmable priority scan. The Challenger Plus™ UHF mobile (30 Watts) and VHF mobile (40 Watts) feature 19 channels and dual priority scanning. Both Challenger models offer multi-tone Call Guard™, multi-code digital Call Guard, a timeout timer, a monitor, and a user-programmable scan list.

For complete details, contact *Diversified Energies, Inc., E.F. Johnson Company, 201 South Seventh Street, Minneapolis MN 55402.* Reader Service number 156.

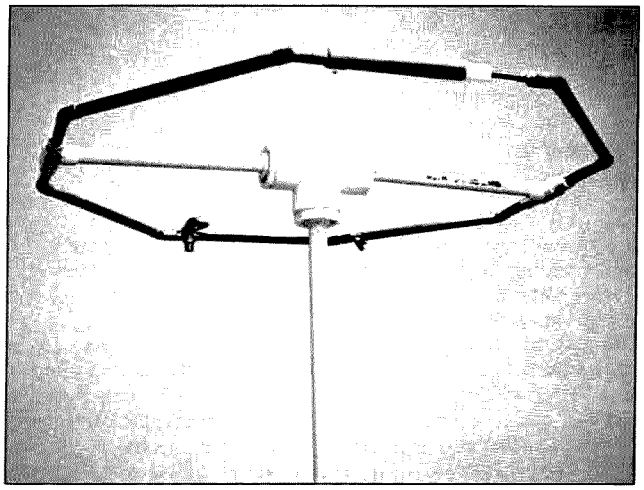
8-POLE CRYSTAL FILTERS

International Radio now has 8-pole crystal filters available for the Kenwood TS-440 and the ICOM IC-751, IC-751A, IC-730/740/745, R-70/71, and IC-271/471/720/720A. Prices range from $60 for individual filters to $150 for a 2.1-kHz matched SSB crystal set.

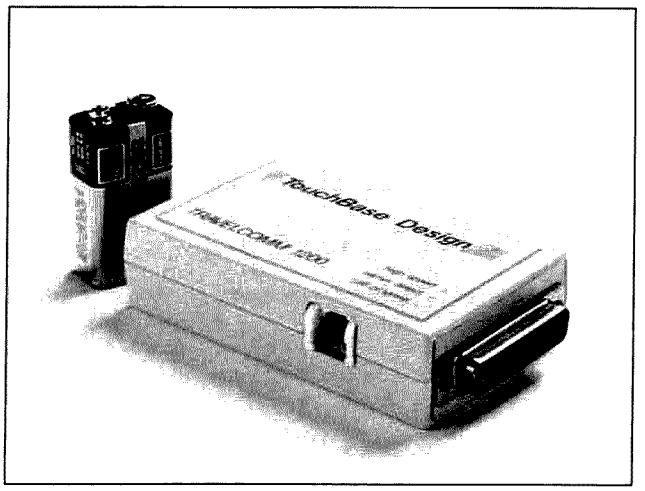


For a brochure describing these and other products, send an SASE to *International Radio, Inc., 747 South Macedo Blvd., Port St. Lucie FL 33452.* Reader Service number 157.

MOBILE CATALOG



A 56-page catalog of mobile antennas, portables, and accessories for the mobile market has been published by Antenna, Inc. Complete mechanical and electrical specifications are offered



The ICOM IC-48A.

E.F. Johnson's Challenger™ VHF/UHF mobile radio.

Advanced Design Network's Microloop antenna.

The TravelComm 1200 portable modem marketed by Technigroup.

for antennas covering 25–1,000 MHz.

To receive a copy of the catalog, write or telephone *Celwave, Route 79, Marlboro NJ 07746; (201)-462-1880.* Reader Service number 159.

MICROLOOP ANTENNAS

Advanced Design Networks has announced their Microloop series of small HF antennas. Across-the-loop dimensions range from 27 inches for 10 meters to 104 inches for 40 meters. The antennas may be mounted horizontally or vertically, and can handle 200 Watts PEP.

A six-page overview of Microloop design concepts and installations is available by writing *Advanced Design Networks, Inc., 8601 66th Street North, Pinellas Park FL 33565.* Reader Service number 154.

APPLE TEKDRAW

Tekdraw, a graphics software package for the Apple *II* family, is now available from Computer Aided Instructional Systems. Using Tekdraw, you can design schematics, circuit boards, architectural layouts, certificates, charts, graphs, and so on. The Koala Pad, a joystick, or game paddles may be used as the input device.

The system includes predrawn symbols which can be selected, rotated, and positioned on the screen. Tekdraw will save, recall, and print your designs.

The software package, including a graphics utility section, sells for $69.95. For more details, contact *Computer Aided Instructional Systems, Box 177, Building 5, Service Drive, Holly MI 48442.* Reader Service number 161.

TRAVELCOMM 1200™

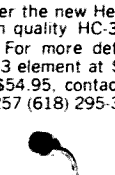
Technigroup, Inc., has announced the TravelComm 1200 portable modem. Designed for use with portable computers, the 300/1200-baud modem operates for about thirty hours on a 9-volt battery (included). Connection to the computer is made via a DB-25 (RS-232C) connector, and an RJ-11 modular phone jack handles the telephone line (a phone cord is provided with the modem).

For further information, please contact *Technigroup, Inc., 16 Green Acre Lane, Northport NY 11768; (516)-261-0423.* Reader Service number 162.

MIRACLE RODS

Miracle Rod of Glasgow, Kentucky, now offers a low-temperature brazing rod for aluminum. The fluxless rods may be used with a propane torch to repair breaks in antennas, to braze cavities, and to weld joints as simply as soldering. The rods have a high conductivity, and melt at 730–740 degrees.

For complete information, please contact *Miracle Rod, PO Box 791, Glasgow KY 42141.* Reader Service number 160.



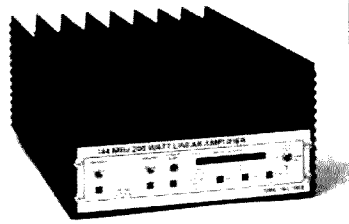
The Key Element

SSB clarity starts at the microphone...

If you are not satisfied with the 'sound of your station'—it's no wonder—most "communications" mics you use were designed for industrial paging or p.a., not for the sophisticated SSB techniques. The HC-3 response gives maximum articulation for getting through DX pile-ups and has set the new standard for all.

You can easily install this small, advanced Heil element into your present old mic or order the new Heil HM-5 SSB mic using the high quality HC-3.

For more details or to order the Heil HC-3 element at $19.95, the HM-5 SSB Mic at $54.95, contact HEIL, LTD., Marissa, IL 62257 (618) 295-3000 (add $3.00 shipping).



Hams who care about maximum results in getting over, around and through DX pile-ups now have another weapon in their arsenal. The Key Element!

HEIL SOUND

Hearing Is Believing...

Ampro Little Board

by George M. Ewing WA8WTE/4

Ampro Computers, Inc.
67 E. Evelyn Ave.
Mountain View CA 94041
Ampro Little Board™—$249

There is a phenomenon in a rapidly growing and changing technology like personal computers that is usually called the "price knee" or "crossover point." This is a point in time in which the price for an older generation of machines is dropping quickly, and the cost of the new generation, initially fairly high, is also starting to fall. At some point, the cost-effectiveness ratio crosses over, and the new technology becomes cheaper and better than the old, even though the price of the old may be falling faster.

At some time in the last year or two, we appear to have reached that point with 8-bit CP/M computers. The older machines, such as the Heath H-89 and others that use the 8K 4116 memory chips plus large numbers of TTL and LS-family chips, are being replaced by newer machines designed from scratch to take advantage of the more efficient 64K DRAMs, custom LSI, and other technologies that lower the chip count and reduce power consumption. Of course, the stiffest competition is actually from the rival 8086/8088 and 68000 CPU families, but even within the CP/M world, things are changing fast.

Why a CP/M machine? There are a tremendous number of inexpensive or free public-domain programs available that are of interest to the amateur, everything from elaborate RTTY and logging programs to those for circuit analysis and filter or antenna design.

A good friend of mine, Jeff KB2JN, had been planning for some time to get an inexpensive CP/M computer to supplement his IBM PC and other personal and home machines. He looked at a number of options, including a used Heath H-89 or H-19 upgrade, an Apple with 80-column and CP/M cards, a Commodore 128, or the possibility of building up a system using a surplus Xerox 820, Big Board, Kaypro, Televideo, or Osborne board. After much deliberation, he decided instead on the Ampro Little Board, and I agreed to help him put his system together despite my built-in prejudice in favor of Heathkit/Zenith products. The rapidly dropping price of the Little Board, coupled with its simplicity, small size, and relatively low power consumption, made it look very promising.

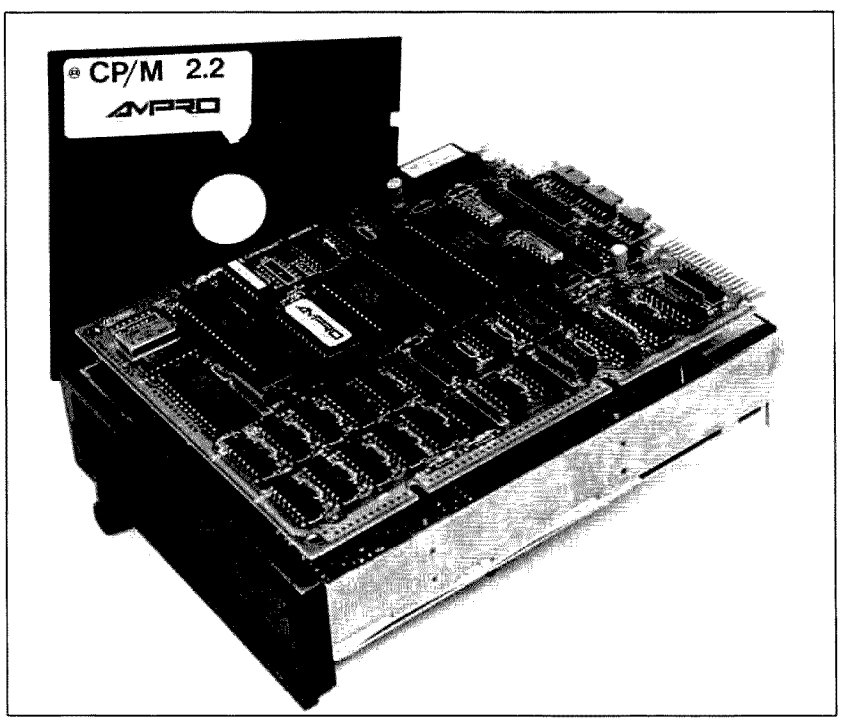

Photo A. The Little Board Plus, which includes an SCSI interface.

Equipment Needed

The Ampro Little Board (this discussion is only about the Z-80A CP/M machine—Ampro also makes a 16-bit MS-DOS Little Board) is designed to fit in the same physical footprint as the PC board for the typical 5-1/4" disk drive, and to be compatible with the same voltage and power requirements. The power connector is even the same edge connector that most drive manufacturers use. This makes packaging a homemade Little Board system a snap; almost any surplus drive enclosure or larger terminal will do.

A sheet of surplus 1/2" acrylic plastic picked up for a dollar at the Rochester, New York, hamfest flea market was adequate as a base plate for Jeff's ham-shack system, since we intended it to spend its whole life in the same spot on a shelf. For a system that is to be moved around, a surplus drive enclosure or one of the low-profile metal cases sold for IBM or Apple clone builders is fine, or the board can be mounted with a little effort in most terminal enclosures. The small size and low power consumption (and less resulting heat) make this a good option.

Besides a cabinet, the Ampro builder needs a power supply, 5-1/4" soft-sector disk drives (up to four), and some kind of RS-232 serial terminal to act as a console. (Unlike the Xerox-820 and Big Board, the Little Board requires a separate full terminal instead of just a keyboard and monitor.) All these items are available at reasonable cost; check surplus and mail-order catalogs and the ads in ham and computer magazines. We decided to use a surplus IBM 60-Watt power supply, perfectly adequate for the Little Board and a couple of drives. These supplies are widely available and a real bargain right now, as thousands of IBM freaks are pulling them out of their PCs and replacing them with heavier supplies for a hard-disk upgrade.

We selected two full-height 40-track drives, as the full-height drives are usually cheaper than half-height, and space was no problem with our layout. If you're going to stuff a couple of drives into a Heath H-19 terminal case or build up a briefcase portable RTTY machine, half-height drives might be worth a few extra dollars in saved space. If you're operating battery portable, the newer half-height drives may also use a little less power.

If the power supply you're using doesn't already include a cooling fan, putting in one of the smaller, quieter muffin fans is good reliability insurance. The thermal design and layout of your enclosure will determine if it's absolutely essential, but it's silly not to include a

fan except in the most extreme low-power, battery-operated briefcase designs, where every Watt-hour is critical.

For a terminal, Jeff decided for the time being simply to use his existing IBM PC in terminal mode with a public-domain communications program. If you don't happen to have an IBM PC lying around, another possible option is to use an inexpensive home computer such as an Atari or Commodore, with a serial port configured as a terminal. New Atari 800XLs were going for $39 or 3 for $99 in local toy stores around Christmas last year! Inexpensive surplus terminals also are widely available. If I decide to build this system for myself, I'll probably look for a good used Heath H-19, as it already has a front-panel knockout for two half-height drives. The similar Radio Shack DT-1 is another good bet.

Remember, though, that the terminal you choose will have some effect on what software will work with the computer. Public-domain programs that are written for a particular keyboard and display, such as a Heath-19 or a Lear Siegler ADM-3A, may need to be modified to work with a nonstandard keyboard and display. I would not recommend a 40-column display for serious word processing or spreadsheets, for example. For RTTY and CW operating, or for routine QSL logging and calculations, a cheap,used home computer and a junk B&W TV set may be perfectly adequate.

Besides the main components already mentioned, you'll need some cables and connectors. The drives need 34- or 35-conductor ribbon cable and standard 5-1/4" disk-drive edge connectors, one more than the number of drives, as the connector on the Little Board is identical. If you are building a two-drive system, you'll need three connectors; for a four-drive system, five; etc. If you wire the connectors yourself, make sure that the signals are on the even-numbered conductors and the odd ones are grounded.

Using shielded ribbon cable and keeping the length as short as possible will help reduce RFI, both in terms of QRM generated by the computer and computer glitches cause by rf from the station transmitter getting into the system. A grounded metal enclosure for the system plus filtering and bypassing on the power cord will help, too.

Check your Ampro manual and the data sheets and schematics for the drives themselves. Normally, a terminating resistor network goes only on the last drive in the chain and is not needed on the others. You'll also need a power cable and connectors for the board and drives and provisions for bringing the power-on light and reset button line out from the board connector to a convenient location.

The WD-1770 disk-controller chip can handle up to four soft-sector drives in various combinations of single- or double-sided and 48 or 96 tracks per inch (tpi)—40- or 80-track. The CP/M boot disk provided by Ampro is single-sided, 40-track, however, so you'll need at least one of these drives to get your system up and running. Also, in order to use DISKCOPY (one of the disk-copying utilities provided with the Little Board operating system software), you will need at least two drives of the same kind.

The (Original) Ampro Little Board at a Glance

Board Dimensions	7-3/4" x 5-3/4" x 3/4"
CPU	Z-80A at 4 MHz
RAM	64K (eight 64K DRAM chips)
ROM	One 8-bit (2732) EPROM for initialization
I/O	Two RS-232 serial ports, one 75-9600 baud, one 75-38,400 baud, plus one Centronics parallel printer port. One serial port is used to communicate with any RS-232 serial terminal as console.
Disk I/O	Western Digital WD-1770 disk-controller chip can drive one to four 5-1/4" soft-sector disk drives, in any combination of 48 tracks per inch (tpi) and 96 tpi, single- or double-sided drives. Step rates are selectable.
Power Consumption	+5 V dc @ 750 mA, +12 V dc @ 50 mA (The −12 V dc for the RS-232 serial ports is generated on-board.)
Operating System	CP/M 2.2, plus extra utilities and ZCPR enhancements
Price	$249 list (model 1B-1, qty. 1–4, as of April, 1986)
Manufacturer	Ampro Computers, Inc. 67 E. Evelyn Ave. Mountain View CA 94041 (415)-962-0230

(Note: Since KB2JN and I began this project, Ampro has begun phasing out the Original Little Board in favor of a newer version, the Little Board Plus, which includes an added SCSI interface on the same size circuit board. They also now sell a line of piggyback SCSI I/O and STD bus boards which will work with other Z-80 computers as well as the original Little Board. Interested amateurs should inquire about prices, etc., as they probably will have changed by the time this review sees print.)

Documentation

The manual provided with the Little Board has 135 8-1/2" x 11" pages. About a third of this is assembly and operating instructions for the user, and the rest is reprints of data sheets for the key ICs, such as the Z-80A CPU and the Western Digital WD-1770. This seemed a bit on the skimpy side at first to an old Heath/Zenith user, but if you consider the fact that the Little Board not only comes assembled and tested except for cables and peripherals but is also inherently much simpler than older generation Z-80 machines, the manual is more than adequate for the everyday routine user.

Ampro does provide an optional Technical Support Package for customers who are going to use the Little Board in custom or OEM applications. I prefer a large schematic with everything mapped out on one sheet, but the modular schematics provided with the Little Board are clear and easy to read, adequate for most routine troubleshooting.

Software

As for software, the Little Board comes with two complete operating system CCPs, both regular Digital Research CP/M v. 2.2, and ZCPR3 (an enhanced operating system that is compatible with regular CP/M but includes more sophisticated capabilities). You could write a book-length review just on ZCPR; many user groups have several disks filled with help files and special utilities. The most obvious advantages for the beginner are the way file directories and user numbers can be manipulated. ZCPR will allow you to make a file of any disk's directory without retyping, and will shuffle files from disk to disk and user area to user area very easily—something that is difficult or impossible to do from stock CP/M.

ZCPR will also create an optimal path search for a file that's not on the currently logged disk, and the DIR.COM version of the directory utility provided by Ampro allows an almost mind-boggling array of possible arguments and parameters in addition to the stock CP/M DIR A: or DIR B:. You can hide secret files in different user areas and still access and execute them from the currently logged user area and disk—once you know how. This might be important for classroom use, where different students may have to share disk files in different user areas. For myself, being able to PIP together a comprehensive disk library directory without hours of retyping is the most valuable feature.

Besides the usual CP/M utilities like PIP, ED, STAT, and so on, Ampro provides other utilities. AMPRODISK allows you to format, copy, and verify a disk. This is similar to the combined utilities of FORMAT and DUP from Heath and some other manufacturers. MULTIDISK.COM allows you to read and write to other soft-sector CP/M (and CP/M-86) disk formats. It will not allow reading and writing of Heath/Zenith hard-sector or Apple 35-track formats, though. UNERASE.COM allows you to recover an accidentally erased disk file, providing that the disk hasn't been physically over-written or reformatted. STARTUP.COM allows automatic execution of programs upon

power-up or reset. MULTIFMT.COM allows you to format a blank disk in other soft-sector formats, including CP/M-86 formats for some 16-bit computers. SWAPCOPY.COM allows you to copy files from one disk to another using a single drive. DISK7.COM is a sort of enhanced combination of STAT and PIP for manipulating files.

The Multidisk and Multiformat programs are very impressive and support a wide assortment of disk formats, including relatively obscure ones such as Heath Lifeboat and TRS-80 Montezuma CP/M. To use the programs, one of the regular drives is reconfigured as disk E: (for Emulate) and the parameters are selected from a menu.

Conclusions

The Ampro Little Board is a very good little, single-board computer. Besides the small size and low power consumption already mentioned, there are several other positive features. The Z-80A runs at 4 MHz, twice as fast as many early CP/M machines. The memory-management and refresh circuitry is entirely digital, and does not have discrete RC networks, one-shots, and other parts cluttering up the path. This, combined with the physically small size and low chip count, makes for very reliable operation.

One of the two RS-232 serial ports provided will run as fast as 32,400 baud. If your terminal can handle it when serving as a console, running at 19,200 or 32,400 baud instead of the older standard of 9600 baud will result in an amazing speedup in writing to the screen, especially important with I/O-intensive programs like games with graphics. Actual graphics capability will be limited, of course, by your terminal and the CP/M software you are running.

The price has fallen to true bargain levels; Ampro factory ads in ham magazines dated January, 1986, give a list price of $249 in single-unit quantities, and some dealers may even discount this. This is $50 cheaper than just a soft-sector controller card for Heath H-89!

On the negative side, the most serious limitation on the original Little Board is the fact that you have only two RS-232 serial ports and one Centronics parallel printer port. With one serial port tied up talking to your terminal as a console, that leaves just one, putting you in the same boat as stock Kaypro II users. If you want to use both a modem (or RTTY TU) and a serial printer, for example, you have to kluge up a switching or transfer box, or else use an extra-cost parallel-to-serial adapter on the Centronics port to drive the printer.

Also, the serial ports support data only on pins 2 and 3, and handshaking on pins 5 and 20 (CTS and DTR). If you have a fancy modem that uses other lines for handshaking, carrier detect, etc., there may be some problems getting it working, especially for the relatively inexperienced beginner. Unlike some other computers, there is no physical difference between a DCE and a DTE port, which can also be confusing for a beginner. The manual does explain how to get a modem working by inverting pins 2 and 3 plus 5 and 20, though.

Unlike the older Z-80 computers such as the H-8, H-89, and many S-100 systems, there is no bus expansion connector on the original Little Board. This makes adding extra I/O ports and other hardware options fairly difficult. About the only practical approach is for boards that plug piggyback directly into the Z-80 socket. There is at least one manufacturer of clock/calendar boards that work this way and that are relatively inexpensive. Ampro does sell an SCSI expansion card as a $99 extra-cost option to allow additional I/O to be added, and the company has announced a new version of the Little Board, the Little Board Plus™, which includes the SCSI port on the card for about $40 more. This looks like a worthwhile option for more ambitious users and is cheaper than buying the Little Board and SCSI card separately, or even the $59 SCSI upgrade kit. Ampro also sells hard-disk packages, an STD bus adapter, and other options.

In closing, then, the Ampro Little Board is an inexpensive, reliable, and physically small CP/M computer. For applications like custom briefcase computers or low-cost systems for a student or amateur on a budget, it's a good buy indeed. Reader Service number 151.■

Hamcom Terminal Software

by E. Benson Scott AE5V

Advanced Electronic Applications, Inc.
PO Box C-2160
Lynnwood WA 98036
Hamcom—$49.95

With the advent of digital communications and the increasing use of computers in the shack, one is always looking for easier and more efficient ways to combine functions. AEA (Advanced Electronic Applications) markets a program written and supported by Emile Alline NE5S. The program, Hamcom, produces a complete Morse, Baudot, ASCII, and packet communications program for the IBM PC or compatibles. The software has been revised several times; I'll review 4.E, the most recent version. No more will you have to have separate programs for RTTY and packet communications; Hamcom has combined the best of both worlds into one very usable terminal program.

The software is written in Basic, with files on one double-sided, double-density disk. The programs have been compiled to facilitate use and speed enhancement. Other than a brief instruction sheet for setting up the interface connections and a two-page review of the program, all documentation and instructions are included on the disk and can be read from the screen or printed. When printed, the material is 5-1/2 full pages of information including a very nice summary of the control functions.

The setup and default menu is easily and quickly configured. No special knowledge of the computer is required. Line widths from 30 to 80 characters can be programmed. Ten pre-program messages in each code (ASCII, Baudot, CW, and packet) can be written at this time or at any later date. One nice feature is available for those individuals with early IBM equipment with single-sided format: The program is set up so that owners can use single-sided disks in drives A: and B: and not have to purchase double-sided, double-density disk drives.

An IBM PC compatible computer or PCjr with a minimum of 80K of RAM is required. One serial port is necessary to receive the information from the packet TNC or RTTY/CW demodulator.

Codes

The program is menu driven: ASCII, Baudot, CW, packet, setup, and CW practice are options that can be selected. After one decides which code format to use, the next set of options—setting up speed and other parameters—immediately appears. For the advanced user, more unusual formats can be transmitted and received, but for the neophyte, there is nothing to know except which code and speed are desired.

The ASCII section of the program normally operates at 110 or 300 baud, but is variable enough to allow essentially any combination of baud, bits, or parity allowed by DOS.

The Baudot section allows transmission and reception at 60, 66, 75, and 100 wpm. These options should allow for reception of all but the most unusual protocols.

The CW section allows transmission and reception at any speed from five to approximately 100 wpm and is primarily limited by the demodulator interfacing with the radio and computer.

The packet radio section allows one to transmit and receive packet radio using a terminal node controller (TNC). Variable communication rates are allowed between the computer and the TNC.

A very useful portion of the software includes CW practice. Characters may be sent at a fixed rate or as you enter them into the keyboard. For those learning or practicing the art of CW, character speeds are not dependent on word speeds, and variable spacing is quite easy to incorporate into the setup. The speed will slowly but automatically increase if you desire.

Features

Each of the code formats uses a split-

screen technique, allowing transmit and receive buffers to remain independent. Should you have a color monitor, color options are available. Splitting the screen is a status line, which can be moved up or down. This line includes the format, speed, transmit or receive status, local time and date, as well as the disk-saving status, printer status, diddle, and WRU status.

Pre-programmed disk-saved messages up to 256 characters are allowed in each of the code sections of the program, making a total of 40 available. This is a nice feature in that the RTTY station can be listed in the RTTY section of the program and will not interfere with the description of the packet station in the packet portion of the program.

A more unique and fun feature is the ability to capture and save text in either the transmit or receive mode "on the fly" using function keys. Tapping the function key the first time begins the capture; tapping it a second time ends the capture. This material can then be saved or entered into text at a later time with a two-keystroke entry. The transmit and receive buffers are not limited by the program, only by your hardware capacity.

Interfacing with a TNC or RTTY/CW demodulator is quite straightforward. For using most of the newer demodulators or TNCs, all one has to do is plug one end of the RS-232 cable into the computer and the other into the demodulator or TNC. For those with other connection options, instructions come with the program for connecting the push-to-talk (PTT) line, CW transmit-receive lines, ASCII/Baudot transmit-receive lines, and ground.

Conclusions

Packet radio is the most rapidly growing fragment of our hobby. With Hamcom, a terminal program is set up to work with a TNC, alleviating a number of problems associated with some computer terminal programs (such as not allowing control characters other than the standard letters, numbers, and spaces to be transmitted). The packet portion of the program is also different in that it allows you to transmit and receive essentially simultaneously. Transmitted lines are shown in reverse video.

For the beginner, a very useful feature is the ability to use the Hamcom program without it being attached to a demodulator or TNC. In this way, one can become quite adept at using the available functions without confusing all those listening on the air.

Having used several other RTTY programs for other computers and dedicated terminals, I found this software package easy to use and thoroughly thought out. There are very few RTTY/ASCII programs available for the IBM PC. Because the PC is one of the least frequently used computers in the hamshack, software is not as readily available as for some of the smaller computers, such as the Commodore. If one is looking for a computer terminal program to function with a variety of interfaces and provide flexibility, AEA's program might very well fit the bill at a reasonable cost. Reader Service number 152.■

"When You Buy, Say 73"

CUT YOUR LOSSES

Portable radios can be a trade-off. In return for mobility you get loss of performance.

Well now you can cut your losses significantly. All you need is the new Larsen UHF KūLDUCKIE® KD14-HW half-wave antenna.* It's a mouthful but it'll do your ears a lot of good.

Because it's half-wave, the KD14-HW is fully resonant despite the poor ground plane portables are faced with. Under ideal ground plane conditions, it delivers performance equal to a full quarter-wave. And that's a powerful improvement over most portable antennas!

And because it is inherently resonant, the KD14-HW can also be easily remoted with a length of coax.

The KD14's flexible, easy-to-get-along-with radiating element measures a scant 12 inches. At the base is a 3¼ inch impedance transformer that gives added strength.

The KD14 half-wave series is also available in a collapsable 2-meter version.

Cut your losses and improve your gain when you operate with the new Larsen UHF KūLDUCKIE® KD14-HW, with no-nonsense warranty. You can see it at your favorite amateur dealer.

*For units with BNC output.

A Packet Primer

First you've got to know the lingo.

Packet radio is now very popular, and dozens of amateurs purchase new equipment weekly to get on the air using this new mode. This article will discuss why this new mode is so popular and evaluate the advantages of using packet in comparison with other digital modes.

Join the Packet Radio Revolution!

You may recall that the introduction of machinery into manufacturing during the 18th century greatly changed the way of life in England and other countries. That major change, called the industrial revolution, substituted the power and speed of machinery for the power of man's own muscle and that of animals. That revolution has shaped our way of life today more than anything else.

Today there is a revolution going on in the technical world that ranks in importance with the industrial revolution. Many persons are calling it the information revolution—and packet radio is a part of it. This revolution is based on bringing the power of computers to the process of handling information. It has already changed our way of living and will continue to do so in the future. Its theme is well expressed in an advertising phrase used by a large corporation: Men should think, machines should work. The advent of computerized data processing allows people to emphasize their creative skills and leave the sorting, filing, retrieving, and moving of information to the machines.

The information revolution is primarily sparked by the science of microelectronics, which produces integrated circuits. The lure of something for nothing is very appealing. Haven't you ever wished that you had a printing press to run off a few greenbacks? Well, that's almost the way it is with integrated circuits. Greatly simplified, the process is a form of printing. Much time goes into designing the circuits and photo masks and setting up the equipment, but when everything is completed, the production line turns out thousands of circuits for pennies each. In fact, for many medium-scale integrated circuits, the cost of the package is greater than the cost of the silicon chip inside.

The above trivia is at the heart of the information revolution and the explosion of microcomputers. The spread of microprocessors has been dramatic, covering far more than just microcomputers. I know there is a microprocessor in my microwave oven, my clothes washer (I took it apart), and my automobile ignition, air conditioner, and cruise control. No telling what other device has one in it. The same is true of the ham shack. My handie-talkie, mobile FM rig, HF transceiver, and VHF multimode rigs all are microprocessor controlled. They do the work (when I can remember the proper commands) and I have the fun.

What About Packet Radio?

I believe packet radio is the branch of the information revolution that extends into amateur radio. The power of the microprocessor enables us to have new and more reliable forms of communication. Over the next few years we will see tremendous improvement in the way we are able to pass along information. Packet will not replace CW or phone modes because they are practiced for the enjoyment they bring, but we will see a powerful amateur digital network created that will transform the way we communicate.

At its most basic level, packet is simply another way for amateurs to pass information between them, and in that respect it is no different from the spark-gap transmissions used by the early practitioners of our hobby. With microprocessors in our bag of tricks now, we can move more information in more interesting ways. Each new mode in amateur radio over the years has added to the quality or quantity of information exchanged.

Let me give you an example you must have experienced yourself: Someone visiting your neighbor meets you on the street and comments on your antenna farm. He mentions that he knows a ham just down the street back home and wonders if you could call him to see how things are going. You wonder how to explain the difficulty of contacting that ham—you don't know his callsign, his equipment, his operating habits, etc. It would be a multi-million-to-one shot to turn on your rig and contact him, even if you knew his callsign. So you make some excuse and suggest that he use the telephone.

Now look at how that scene might play when we have an amateur digital network.

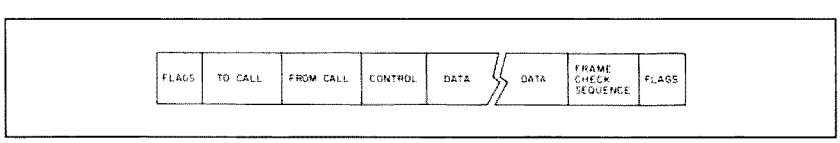

Fig. 1. Schematic representation of a frame.

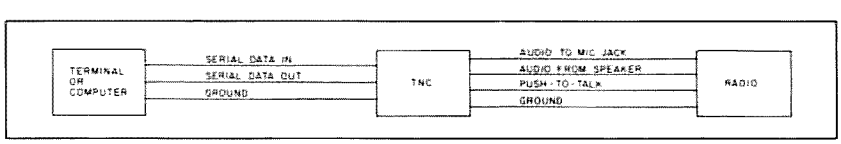

Fig. 2. The minimum equipment required to get on packet.

You obtain some portion of the back-home ham's identification: perhaps his last name and city or his street and city. Then you use your packet terminal to access the network information server. You provide it with the information you have obtained and in turn receive a listing of possible names, callsigns, and addresses, plus any needed routing information. Your visitor can then identify the amateur, and you can send a message using the network. If the other ham is currently on the air, the message is delivered right away. If his station is not operating, the message is stored for him and you are informed of the situation. It's rather like making a phone call, but it is all done via amateur radio. Using the same techniques, you could also have sent him a text file, a computer program, or a video display or picture, or even operated his equipment remotely. Very convenient!

One of the words we hear all the time is "digital." In the strictest sense, hams have been doing digital communication for many decades—they call it CW. Radioteletype (RTTY) and more recently amateur teletype over radio (AMTOR) have become popular forms of digital communication. Packet is also digital, but it has increased capabilities compared with other digital modes because of the advanced techniques used to address and transmit the information.

What Does Packet Do That Other Digital Modes Do Not?

Packet offers several distinct advantages over older digital modes:

1. Robust error detection. It's 1,000 times more comprehensive than AMTOR.

2. Networking. The packet addressing technique allows a series of stations to repeat packets to each other, thus forming a network.

3. Compatibility with computers. Packet supports the transfer of binary data (computer programs) and is the only error-detecting mode supporting the full ASCII encoding used on most computers found in the ham shack.

4. Compatibility with other modes. Packet may be used to transfer any type of information that is in digital form. Thus with proper encoding, the advantages of error detection and networking may be applied to voice and video signals.

5. Speed. HF packet operates at 300 baud, which is some five times faster than RTTY or AMTOR. On VHF, the FCC allows higher speeds, and 1200 baud is commonly used. That is 10 to 20 times faster than RTTY. In the future, data rates of 9600 baud, 56,000 baud, and higher will be used.

Protocols

A protocol can be viewed as a set of exact rules that describe the actions one takes in response to the actions of others, or the actions one should take to elicit a certain response from others. In human interaction, protocols are usually referred to as "etiquette." Most protocol specifications are lengthy, because to be useful they must cover every action and event that is likely to occur.

CW uses a single tone, and the information is transmitted by turning the tone on and off according to an agreed-upon code (Morse). There is a simple protocol for CW

WHAT'S IN A TNC?

The initials TNC (pronounced tee-en-see, and only rarely "Tink") have become synonymous with packet radio in the amateur service. It's the wrong name, but it's too late now. An early amateur digital experimenter designed a device called a Terminal Node Controller as part of a two-part system that included a Station Node Controller. Other experimenters used the TNC as a separate unit in experiments of their own, keeping the same name. The original TNC/SNC project has since faded into the mists of time, and what we now call a TNC is actually a Packet Assembler Disassembler (PAD). A PAD connects a device (such as a terminal or computer) that does not "speak" the network protocol to the network. It collects characters one at a time, assembles them into packets, and sends them out into the network. It also takes packets from the network, disassembles them into individual characters, and sends them to the terminal or computer. If you substitute TNC for PAD when reading non-amateur packet literature, you won't be far wrong.

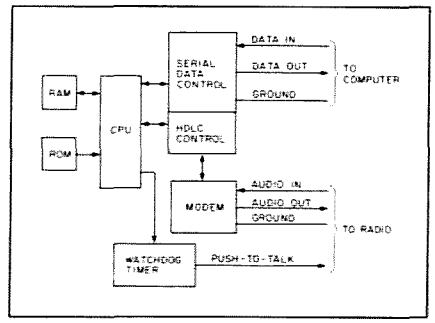

Fig. 3. The major elements of a TNC.

If you open up a TNC, you'll find a general-purpose computer hiding under the hood, chained to a communications chip and modem. As shown in Fig. 3, a TNC is a fairly standard microcomputer, with RAM for storage, ROM for the program, a CPU to make it run, and a serial chip to talk to your terminal or computer. Most TNCs also have an HDLC chip, sometimes as a part of the serial chip. HDLC (High Level Data Link Control) is one of many names used to describe the format of the data sent out over the radio. TNCs with a hardware HDLC chip will be able to run at higher data speeds than TNCs with a "software HDLC." As a practical matter, this is only important if you want to use your TNC with the new satellites coming up (see the article about digital satellites in this issue), or if you want to use the higher speed modems that are beginning to be available. Today, at least, the cost of the units with and without hardware HDLC is about the same.

Another element of a TNC is the modem. The first TNCs did not have modems included as an integral part; the modems were "outboard." In the early days, hams standardized on the Bell 202 modem tones. They did this in following two of the most time-honored of amateur traditions, easy and cheap. Easy—the Bell 202 tones of 1200 Hz and 2200 Hz, designed to fit nicely in a standard telephone bandwidth, also fit nicely into the microphone jack of an amateur 2-meter FM transmitter. No modifications to the radio were required. Cheap—surplus 202 modems were available for less than $100. In the early home-brew days of packet, Bell 202 was the standard, for TNC-based experimentation at least.

When the everything-included TNC kits came out, a modem circuit using the 202 standard was included on the TNC board. After all, the only other people out there to talk to were using home-brew TNCs. Later on, most TNC manufacturers realized that 1200 baud would eventually be too slow, and made their TNCs with a connector that bypassed the on-board modem. This allows for higher speeds, as well as for different standards, such as the PSK modems to be used by the new fleet of digital spacecraft.

The final block in Fig. 3 is the watchdog timer. This is a device that monitors the PTT line that keys your transmitter. The watchdog timer makes sure that the radio is not keyed for an excessive amount of time, should some problem occur in the TNC software. This is not only the neighborly thing to do, it makes the FCC happy as well. Section 97.80 of the amateur rules states: "(a) When under automatic control, devices must be installed and procedures must be implemented which will ensure compliance with the rules when the control operator is not present at the control point of the amateur station."

The watchdog timer is one such device—a cheap and easy way to help make sure that a software or other problem in your TNC doesn't cause your station to come on the air and stay on, jamming out the frequency. Most TNCs have this feature, others have it as an option, and some don't have it at all. If you plan to run your station unattended, look into the matter. To somewhat confuse things, there are two types of watchdog timers. The one included on some TNCs is a PTT timer, but you will sometimes hear of watchdog timers used for digipeaters. These are used to jump-start the TNC itself if it crashes for any reason, and are in general required only for remote locations. See WB6RAL's article on mountaintop digipeaters in this issue.

In general, a TNC contains everything needed to put you on packet radio; all you add is the terminal or computer and a radio.

operators based on prosigns such as KN and Q signals.

RTTY uses two tones, and the information is transmitted by switching back and forth between them (frequency shift keying—FSK) according to an agreed-upon code (Baudot). As in CW, RTTY has some operator conventions on how to hold a QSO, but no real protocol is required.

AMTOR enhances the operation of RTTY by adding selective addressing and limited error detection. It uses a special code based on Baudot. A strict set of protocols defines AMTOR, involving such things as the method of selective calling, error detection, acknowledgment of good data, and timing of transmit and receive cycles. If there is any deviation from those protocols, you're not doing AMTOR any longer.

Packet basically uses the ASCII code for character representation, although binary data (object code) and digitized voice, video, and telemetry may be transmitted equally well. Packet currently uses FSK just as RTTY does, but that modulation technique is not required. Future equipment will use modulation techniques adapted for higher data rates. Protocols are the major source of packet's power and usefulness, and are mainly a matter of software. The protocols used by packet are far more complex than any protocol used in amateur radio to date. This is in part necessary because a computer is inherently less "intelligent" than a human—less so than even the most reprobate kerchunker. A computer has no common sense whatsoever. The kerchunker's sense is debatable.

Protocol History

The microprocessor revolution has made possible low-cost equipment that will automatically follow complicated protocols for the operator. Packet protocols (and hardware) have been adapted from commercial computer terminal networks. In a large office building with 400 to 1,000 terminals operating from a mainframe computer, you don't want to run a separate piece of coax to each terminal. In that situation, all the terminals are probably daisy-chained on one run of cable. When the host computer desires to transmit to a particular terminal, it places the identification of the intended terminal in the header of the message. All terminals listen to all messages and only the one seeing its own identification will respond to the message.

Packet radio uses this same technique, except an rf channel is substituted for the cable. The formats used in addressing the messages, the timing factors in sharing a channel, and numerous other items make up protocols. Various layers of protocol deal with different portions of the information transfer. Lower-layer protocols deal with the type of signal voltages and connections, the modulation techniques and data encoding, etc. Higher-layer protocols deal with addressing messages through the network, converting data formats among differing computers and terminals, handling file transfers and remote

BETTER HOMES AND SHACKS—SOME TNC-EQUIPPED STATIONS

Packet radio stations come in all shapes and sizes. Photo A shows a small portable configuration. This is the traveling road-show station used by NK6K at packet demonstrations. There are several portable computers and TNCs that will fit the same footprint. The radio is a 2-meter HT; the 6-volt cells power the TNC. The smallest, lowest power TNC is the GLB PK1-L (not pictured). GLB's ads say the size is 4.5" x 5.9" x 1.0" and it draws about 25 mA typical power. I've seen one running at a show on a 9-volt battery. Packet stations similar to the one shown here have been on boats and planes and in other interesting places. A station very similar to the one pictured here using a Radio Shack TRS-80 Model 100, a specially built TNC-2, a specially modified Motorola radio, and a special container is ready to be qualified to fly on the next Shuttle Amateur Radio Experiment (SAREX) flight.

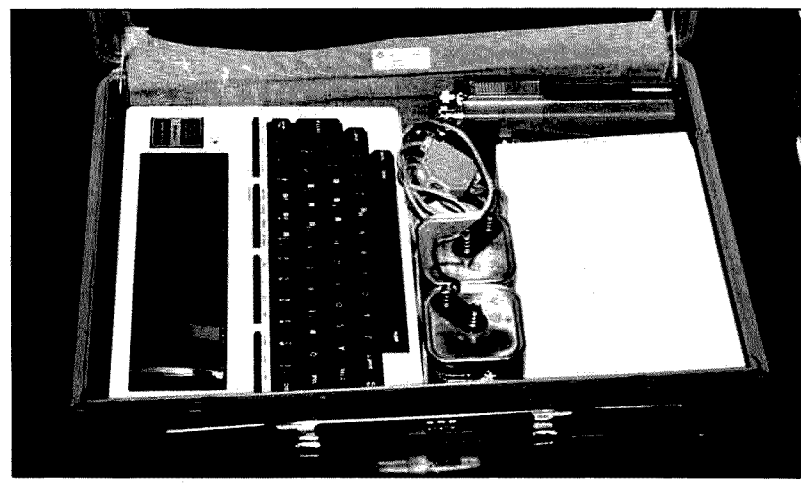

Photo A.

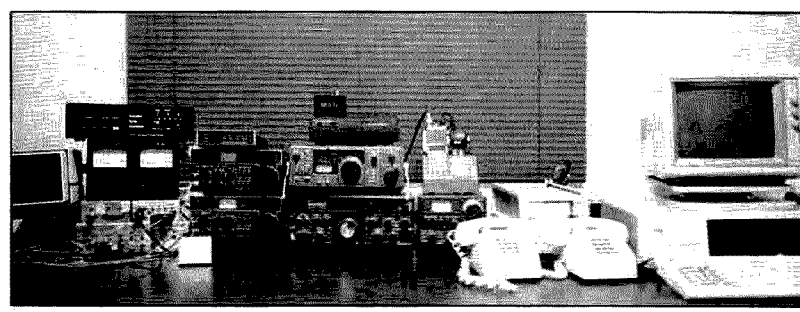

Photo B.

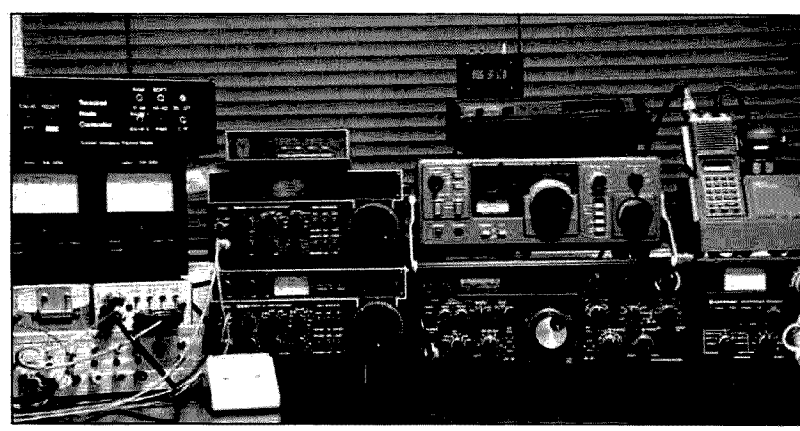

Photo C.

Photo B shows a fully equipped packet station, ready for action on HF, VHF, UHF, OSCAR-10, and UoSAT-OSCAR-11. It is also running a bulletin board system on the IBM-PC. The closeup in Photo C shows (top to bottom, left to right): TAPR TNC-1, azimuth and elevation rotor control for the satellite antennas, Uo-11 command encoder and decoder, power supply, TAPR TNC-2, IC-251 two-meter radio for local packet and satellite downlink, IC-451 430–440-MHz radio for satellite uplink, polarization switches for the satellite antennas, UTC clock (the photo was taken very late at night), Bearcat scanner to receive packets in the commercial bands*, R-1000 general-coverage receiver, TS-830 for HF packet, 440–450 transceiver for local chit-chat, and HF antenna tuner. Packet can be used to enhance your station in whatever activity you're engaged in. Unattended CW DX spotters nets anyone? How about a worldwide EME schedule data base?

Photo D shows Skip Hansen WB6YMH's very neat arrangement for an automated BBS station. The entire station is mounted in a 19″ rack cabinet. From top to bottom are: thin white box housing a TAPR TNC-1, a shelf containing a TNC-2, a phone and dial-up modem, a vintage IMSAI 8080 computer, a UHF and a VHF radio, four 8″ disk drives, the CRT for a Xerox 820 computer, and another white box containing a Xerox 820. This rack actually contains two BBS systems, one on packet and one attached to the phone lines. There is no connection between the two systems, which is the best way to avoid third-party problems. The Xerox 820 runs a standard CP/M system; WB6YMH-2 is a host, file-server, and a mailbox system.

Photo D.

Photo E shows a very simple system consisting of a two-meter radio (with amplifier), an Apple-II computer, and a TNC-1 mounted in the black box under the CRT. The photo is actually deceptively simple, since this station is also the busiest BBS in the Los Angeles basin. A station need not be sprawling to get a job done. This station is N6BGW-9, run by Scott Avent.

*I'd like to point out that amateur TNCs which were designed by hams in garages are in use in the commercial services. TNCs are in use in a variety of places around the world doing various jobs. This is the best example in recent years of amateurs living up to Part 97.1(c) of the FCC rules: "Continuation and extension of the amateur's proven ability to contribute to the advancement of the radio art." Why are amateur-designed TNCs showing up in the real world? They're cheap and easy to use, of course. Amateur doesn't mean unprofessional.

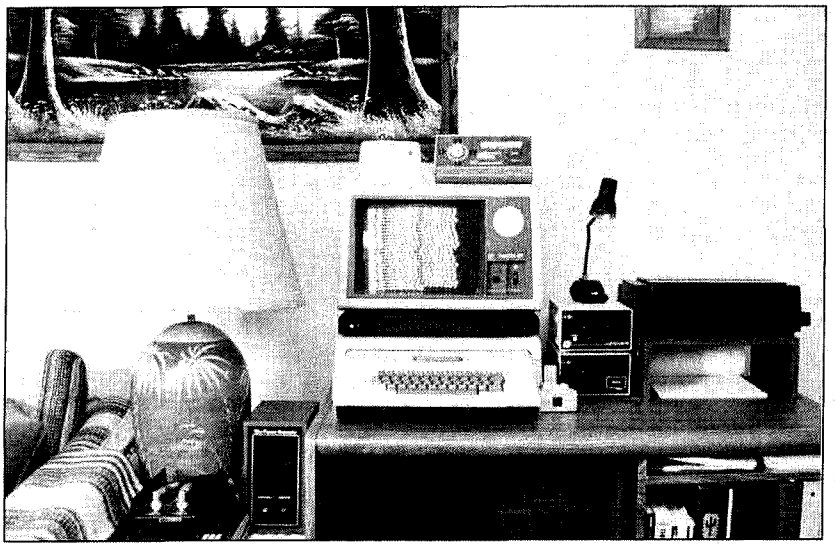

Photo E.

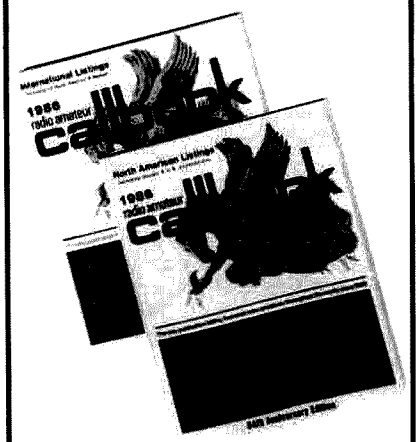
data-base accesses, etc. At the highest layer, protocols deal directly with the user or his program and perform work for the user without making him aware of the part the network is playing.

AX.25 Protocol

Much of the progress to date in packet radio is due to the adoption of a standard link-layer protocol that makes packet equipment from all manufacturers fully compatible. This protocol is AX.25, the amateur version of the international X.25 protocol. Other protocols were used originally, and some areas have not converted to the AX.25 standard, but layer 2 protocol is no longer an open issue. Development and experimentation with layer 3 and 4 protocols is going on, but no standardization is likely in the near future. Much experimentation will be done to determine which method(s) will work best in the amateur-radio environment.

What Does a Packet Look Like?

A more appropriate heading here probably would be "What does a frame look like?" A TNC transmits frames, which include flags, addresses, commands, information, and error-checking information. The user's information is properly called a packet of data. Popular usage, however, calls the whole frame a packet. The frame begins with a flag consisting of a special series of ones and zeros. (Remember, at the digital level, everything is either a one or a zero.) Next come the callsigns of the sending station, the station intended to receive the frame, and all those stations that are to repeat the frame on the way to its destination. Then a field identifies the type of frame being sent—connection request, acknowledgment, or status polling, for example. If the frame is supposed to contain data, the control field is followed by a packet of data.



Next comes an error-checking field, which works like this: The entire frame (including addresses, etc.) is made an input to a mathematical formula (think of it as long division). The remainder from that operation is included in the frame in the Frame Check Sequence field. When the frame arrives, the same mathematical formula is applied. If the remainders are equal, then the frame is presumed to be error-free. If the new remainder is not the same, no attempt is made to correct the data. Instead, the frame is thrown away and retransmitted.

Fig. 1 shows a schematic representation of a frame. Remember, a microprocessor takes care of all of this for you, and at the end of the process presents you with the data contained in each frame.

Networking

Protocols make networking possible. The techniques described above for the computer terminals are even more valuable in the amateur environment. While a RTTY or AMTOR station can talk directly to only one other station, packet stations can extend their range by using other packet stations as repeaters. These digital repeaters are not the

1986 CALLBOOKS

The "Flying Horse" has a great new look!

It's the biggest change in Callbook history! Now there are 3 new Callbooks for 1986.

The North American Callbook lists the amateurs in all countries in North America plus those in Hawaii and the U.S. possessions.

The International Callbook lists the calls, names, and address information for licensed amateurs in all countries outside North America. Coverage includes Europe, Asia, Africa, South America, and the Pacific area (exclusive of Hawaii and the U.S. possessions).

The Callbook Supplement is a whole new idea in Callbook updates. Published June 1, 1986, this Supplement will include all the activity for both the North American and International Callbooks for the preceding 6 months.

Publication date for the 1986 Callbooks is December 1, 1985. See your dealer or order now directly from the publisher.

☐ North American Callbook	
incl. shipping within USA	$25.00
incl. shipping to foreign countries	27.60
☐ International Callbook	
incl. shipping within USA	$24.00
incl. shipping to foreign countries	26.60
☐ Callbook Supplement, published June 1st	
incl. shipping within USA	$13.00
incl. shipping to foreign countries	14.00

SPECIAL OFFER

☐ Both N.A. & International Callbooks	
incl. shipping within USA	$45.00
incl. shipping to foreign countries	53.50

same as the FM voice repeaters we are used to. In fact, any packet station can be a digipeater. Remember that each packet station listens to every transmission on the frequency to see if that transmission is addressed to it. It also looks at each transmission to see if it is supposed to be repeated. The addressing information specifies which stations are to repeat the information and in what order they are to repeat it. Thus a chain of repeater stations may pass along a message and carry it a long distance beyond the local area. That is the basis of networking.

Packet Is Fun

Enough of the theory and history! Packet is loads of fun. Thousands of hams use packet for rag-chewing just as they do any other mode. You can share the channel with a dozen other conversations and watch them all at once if you like. Or you can limit your screen to displaying only what is sent by the person with whom you are conversing.

A major pastime on packet is non-real-time communication. Real-time communication is when both parties in the conversation are on the air at the same time. In amateur radio, the further apart two real-time stations are, the greater the chance that one of the parties is either up late, up early, skipping work, or retired. In non-real-time communication, only one party needs to be on the air at a time. The originator of a message leaves the message on a "mailbox," which stores it for later retrieval. This is similar to leaving a written message taped to the refrigerator door for a family member who won't be home when you are. As long as the mailbox is accessible 24 hours a day, communication can occur between two persons regardless of whether they are both on the air at the same time or not. This frees the amateur from the tyranny of the clock—and the ionosphere.

There are numerous mailboxes or bulletin-board stations active on packet. ARRL bulletins, newsletters, computer files and programs, and many public and personal messages are available on these computer systems for access by anyone within packet range (and remember that packet range is greatly extended by the use of digipeaters). The network automatically forwards messages to the mailbox serving the addressee. It is very thrilling (and convenient) to check into your local mailbox and get messages from numerous states and several countries.

What does it take to get on packet radio? The minimum equipment is a terminal node controller (TNC), which is the packet controller; a 2-meter FM radio and antenna; and either a computer or a terminal (see Fig. 2).

The TNC is the device that contains the microprocessor that does most of the work of getting your information sent and received. There are now a variety of TNCs to choose from, in a variety of price ranges and capabilities. There will no doubt be ads for several TNCs in this issue of *73*. Many radio stores have TNCs on display, and most clubs have at least one person on the air with packet. Although it takes many words to describe what packet is, it only takes a few minutes to see what it can do when you get a demonstration.

Packet can be used with any radio capable of sending voice—i.e., those with microphone jacks—and can be sent anywhere the F1 emission is permitted. In practice, taking various gentlemen's agreements into account, packet is in the "RTTY" portion of the HF bands, all but the "CW only" portions of the 6- and 2-meter bands, and everywhere else. Avoid repeaters where digital is not welcome and, of course, don't interrupt a conversation in progress on simplex channels. The most common radio used for packet today is the 2-meter FM rig.

The terminal is any device that has a keyboard for inputting information and commands to the packet controller, and a screen or printer for displaying the information that comes in from the controller. If you use a computer as a terminal, it needs to have communication software to make it act like a terminal. Any software that works with a telephone modem will work fine with a packet controller. In general, any stand-alone terminal will work, as will any computer equipped to handle an external mode. The key words to look for are "serial," "RS-232," and "ASCII."

The Future

As more and more packet stations come on the air, there is increased support for a good network. Since the radio and computer gear to form such a network is not inexpensive, clubs are forming to take on the job of supplying such equipment. Many traditional clubs are showing more packet awareness and will be willing to support a packet repeater or network node, just as they have supported an FM voice repeater in the past.

Satellites will play an exciting and important role in the packet network. OSCAR 10 is used for packet connections, and OSCAR 11 carries the Digital Communications Experiment. Future satellites will provide even more packet services. JAS-1 should be up about the time you read this and will provide a space-borne store-and-forward mailbox capability.

Within a few years, the nationwide network described above will be in place. Certain amateurs or clubs will operate high-capacity micro- or minicomputers on the network to provide on-line access to information of interest to amateurs. This includes things such as special interest groups for various types of amateur activity, indexes to magazine articles, propagation forecasts, and technical data and specifications. It is really going to be convenient, useful, and lots of fun. Please read the additional articles in this series for more information on packet satellites, mailboxes, operating practices, and other interesting information. Join a local or national packet club, get some packet equipment, and "meet me on the keys."■

How To Make Friends At 1200 Baud

W2JUP's guide to AX.25 etiquette.

The first time you hear the stuff, your reaction might be: Your squelch control is open, you've got intermod on 145.01, the Army Reserve has fired up the local military radar site, or even a lovesick wasp with asthma is trapped inside your HT.

So you reset the squelch control, verify that the radar site is not up, and spray the inside of your HT with bug killer. But after you've heard the noise for the nth time, you begin to notice a slightly musical tone to it—once you've realized it's some kind of radio signal. But it's unlike anything you've ever heard on ham radio. You're listening to what many professionals see as the future of data communication, and what some amateurs call the future of ham radio. You're hearing packet radio.

Now that you know that it's packet radio, your reactions may fall into various categories:

- The Archie Bunker types: "Aw jeez, Edith, them theah digital joiks is spreadin' all over and lousin' up all our verce channels."
- The computer-enthusiast types with the lower-class tickets: "Hmm. I guess it's time to think about upgrading my ticket."
- The experienced RTTYers: "Ho hum. It'll never last, it's too complicated for hams."
- The "professional" hams: "Hmm! I wonder how much this will cost."

Regardless of the category into which you fall, these bursts of strange sounds flowing through your loudspeakers represent the latest technology brought into the amateur-radio art from established commercial practices. In addition to digital fun cavorting across the ethereal spectrum with buckets full of bits, bytes, and bauds, packet radio brings a new concept of the "network" to amateur-radio operation.

Although hams have operated nets since the beginning of the service, the packet-network idea is very different: Each packet-network user must work in a manner not previously required—by using "shared resources." In spite of their dedication of time and equipment, unless members of a packet-radio community understand the basic capabilities and limitations of the equipment and the mode and give sufficient thought to planning and living together, the packet-radio network cannot survive.

Different Strokes for Different Folks

Although our packet networks are very new, in many major metropolitan areas you can already see several types of packet operation on a single channel: direct keyboard-to-keyboard live QSOs (like conventional RTTY); keyboard-to-keyboard live QSOs via packet repeaters (digipeaters); sending/receiving "mail" messages, files, and programs between live keyboards and PBBSs; automatic mail forwarding between PBBSs—either direct or via one or more digipeaters; and personal packet mailboxes and packet "answering machines."

Is it possible for all these diverse applications to co-exist on a single channel? The answer depends on the behavior of each packet system operator. This article offers a few collected thoughts and suggestions about: bandwidth of transmitted signals, transmitter keying characteristics and time constants, receiver agc time constants, TNC parameter values (especially "timing"), beacons, and channel courtesy and good manners.

Packet Radio—The Shared Resource

Successful packet-radio operation requires a level of cooperation among station operators previously unknown in traditional CW, SSB, and RTTY practices on HF. VHF packet operation must be carefully coordinated and channelized. The "independent" operator cannot survive; no one stands alone in packet radio. Each packet-radio user has a direct effect on the performance of the network and the network's usefulness to the community.

Several regional and local frequency-coordination councils have already begun to coordinate or "assign" selected channels on VHF/UHF bands to "exclusive" packet-radio service. In many areas, packet operations on the two-meter band are channelized on 20-kHz centers between 144.90 and 145.10 MHz.

We can share our limited packet spectrum resources successfully. Our success depends on each packet station operator paying special attention to factors that were not quite so critical in non-packet days. Let's take a look at some of them.

Bandwidth

Bandwidth is the amount of space we occupy in the spectrum, and depends on the modulation index and data rates. This factor includes the "deviation" of the FM/PM signal, the frequencies of the tones modulating the carrier, keying and baud rates, and the nature of the data being transmitted.

In Part 97.65, the FCC defines bandwidth as "the width of the frequency band, outside of which the mean power of any emission is attenuated by at least 26 decibels below the mean power level of the total emission. A 3-kHz sampling bandwidth is used by the FCC in making this determination."

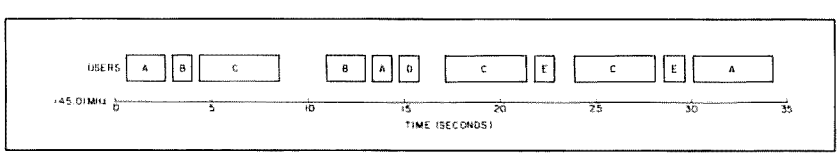

Fig. 1. Packet users share a frequency on a time scale much smaller than any previously experienced in amateur radio. A misadjustment at one station can perturb several others.

Although audio distortion and poor frequency response contribute to increasing the error rate and the packet transmission problem, the bandwidth factor that varies the most and generally does the most damage is deviation—a factor that any operator can easily control. The general rules used in establishing "proper" deviation in voice service are detrimental to your packet's health.

To prevent transmitting an excessively broad FM/PM signal, deviation must be kept *lower* than that normally used in voice service. We must walk a fine line between our deviation being too low, resulting in poor or unacceptable signal-to-noise ratios in weak rf signals at the distant receiver, and deviation being too high for the distant receiver's i-f and demodulation circuits to decode successfully. Either extreme results in high error rates, poor decoding, invalid frames, excessive retries, timeouts, untimely disconnects, and unnecessary reconnection attempts.

Many packet operators use the same radio for packet that they use in voice operation and connect their TNC's AFSK output to the radio's microphone input. In some cases satisfactory results are obtained. When there are problems, they may arise from the way the radio has been set up—microphone amplifier gain and deviation limiting or audio agc action. Most radios coming from Japan (and most of them do these days!) arrive with the deviation set so that the average U.S. ham will enjoy rather high deviation. This characteristic may be due to the fact that in Japan there are few repeaters, simplex operation is the accepted concept, and the radios are set up in factory production test fixtures for some value of deviation obtained with a given value of audio tone input. One theory has it that the input setup values represent the typical soft-spoken local user.

When it's possible, the TNC's AFSK output should be connected to some internal point *after* all speech processing, at the input to the usual varactor modulator. Many radios offer a separate input for tone encoders and DTMF push-button pads. If they're available, that's probably the best point at which to inject the AFSK tones. Any possibility of distorting the AFSK signals by over-driving the microphone input amplifier, diode clipping, or excessive audio agc action can be eliminated.

Carson's Bandwidth Rule defines the approximate bandwidth requirements of communications system components for a carrier signal that is modulated by a continuous or broad spectrum of frequencies rather than a single frequency. In most amateur packet-radio operation, the modulation index (peak deviation divided by the highest modulating tone frequency) will be greater than 1, and the bandwidth is:

$$Bw = 2(Df + 2Fm)$$

Bandwidth equals twice the sum of the peak deviation (Df) and twice the highest modulating frequency (Fm). Table 1 shows these values for the two tones used in VHF/UHF packet radio (Bell 202 tones).

Modern FM receivers have 6-dB i-f bandwidths on the order of 12 to 15 kHz. The better (more selective) the receiver i-f is, the greater the tendency for the receiver to distort highly deviated signals and send distorted audio output to the TNC. The TNC's demodulator may "barf" on the audio, fail to decode the packet frame properly, throw the frame away, and sit there waiting for the retries (the retransmission of a packet whose reception was not acknowledged). Retries are to be avoided, especially when a frame should have been received but wasn't.

During the past several years, I've "fixed" dozens of "I can't connect!" complaints by helping the stricken newcomer to reduce his deviation to a point at which the receiving station's equipment had something better than "square-wave audio" to demodulate.

We must also consider operation on channels 20-kHz wide. If we are to permit nearby packet stations to operate on adjacent channels, it is clear that each adjacent-channel user's peak deviation must be held below 4 kHz to prevent sideband energy from invading the next channel. As a general rule, transmitter peak deviation should be held to a value between 2 and 3.5 kHz. The other guy's receiver will like it, and your neighbor on the next channel will appreciate your courtesy. Don't be a deviant with your deviation!

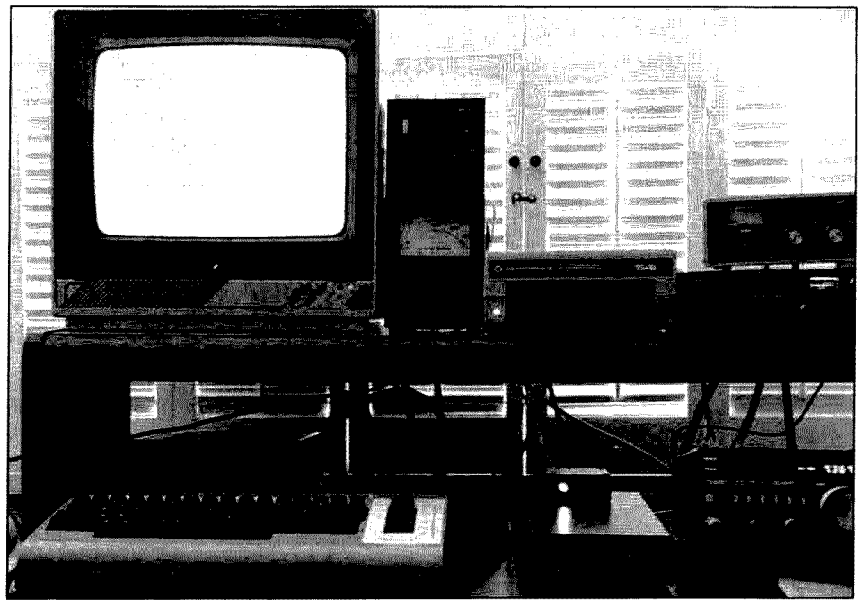

Photo A. One of the more common types of packet stations among new packeteers is the Commodore-64 based system which uses either a stand-alone TNC or a unit specially designed for the C-64—like the one pictured here, AEA's PK-64. This station belongs to Colin Hall, G4JPZ/W6. It features (top to bottom, left to right): CRT, antenna rotor, C-64; antenna switches, antenna rotor; C-64 disk drive, power switch for PK-64 (home-brew), PK-64; HF tuner, VHF radio, HF radio.

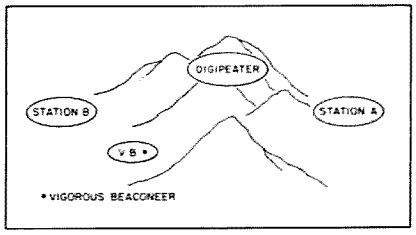

Fig. 2. Station A is shielded by hills and can't hear the vigorous beaconeer. Although station A thinks the frequency is clear, if he transmits while the beaconeer is transmitting, the packets will collide at the digipeater. Packets from station A to station B will have to be retried more often, adding to congestion on the channel.

Software

Many newcomers (and some experienced packeteers as well!) appear to be intimidated by the numerous TNC parameters. Some users seem to be afraid to change any of the values. Well, fear not! Your TNC will not dissolve into a cloud of vaporized chips, nor will your radio leap off the table. There is nothing sacred about most settings. Many values were made variable to permit the user to make changes in accordance with each local circumstance and condition. The specific tuning parameters referred to below reference the TAPR command set used on most TNCs.

A lot of this fear-of-change attitude relates to timing values like FRACK, DWAIT, TXDELAY, and some frame-size and "window" settings like PACLEN and MAXFRAME.

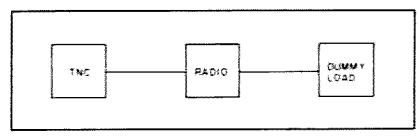

Fig. 3. The proper setup for sending "capture buffer open, digi on" beacons.

Tone Frequency 1200 Hz		Tone Frequency 2200 Hz	
Deviation (kHz)	Bandwidth (kHz)	Deviation (kHz)	Bandwidth (kHz)
1	6.8	1	10.8
2	8.8	2	12.8
3	10.8	3	14.8
4	12.8	4	16.8
5	14.8	5	18.8
6	16.8	6	20.8
7	18.8	7	22.8
8	20.8	8	24.8
9	22.8	9	26.8
10	24.8	10	28.8

Table 1. Bandwidth resulting from modulating an FM signal at various deviations with standard packet-radio tones.

User Type	Time msec	TNC-1 DWAIT	TNC-2 DWAIT
Digipeaters	*	*	*
Keyboard users	160	4	16
BBS/UNIX Nodes, etc.	320	8	32
User file transfer	480	12	48

* DWAIT is ignored for digipeated frames.

Table 2. DWAIT settings for various types of activity.

QRL—I am busy (Don't connect!)
QRR—I am ready for automatic operation (OK connect)
QRU—I have nothing for you
QRV—I am ready
OSO—I can communicate with (callsign)
QSR—Repeat your call on the calling frequency, did not hear you
QSX—I am listening on (frequency)
QTC—I have traffic for (callsign)
QTU—My station is open from (hours-to-hours)
QTV—Listen for me on (frequency)

Table 3. Clever Q-signals that can be used in a beacon text.

Here are some thoughts on the use of the timing parameters available in your TNCs. Perhaps a couple of ideas expressed here might clarify a few implications not fully explained in the vendors' manuals.

FRACK

This value is the number of *seconds* that your TNC will wait for an acknowledgement (ACK) before sending a retry packet. If you have a really good path to the other station and the packets are very solid, you can leave this value at the default setting of 3 seconds. Reducing FRACK doesn't really increase the speed at which packets are transferred. But if the channel is busy and there are many stations on, especially if there's a PBBS (public bulletin-board system) or dedicated digipeater serving multiple users on the channel, you'll probably get better results by increasing FRACK to a higher value of perhaps 6 or even 8. This means that, before your TNC sends a retry, it will wait longer to decide that the other station never got your last packet. This is especially important if the station to which you're connected hears lots of packets from other stations that you may not be hearing.

Remember that these TNCs have CSMA (Carrier Sense Multiple Access): The TNC listens on the channel, and if it hears data—or noise, intermod, or open squelch that it thinks might be data on the channel—your TNC will not key the PTT or transmit data until it hears some kind of silence on the channel, even a bare second. If the other station's TNC is hearing all kinds of stuff besides your signals, and even though it has received your packet nicely, it usually can't send the ACK back to you until it hears a pause in the channel's activity.

The distant TNC may be sitting there having swallowed dandy data, ready to ACK, and meanwhile your TNC (set with too short a FRACK value) thinks that your last packet got trashed and decides to send a second (or third, or...) copy. And so the confusion builds—collisions and eventual timeouts and disconnects are the result.

If you're working into a PBBS (especially through a busy community digipeater), try operating with higher FRACK settings in your TNCs during the busiest hours. These are the times when collisions, noise, and intermod are at their worst levels. Because the PBBS' TNC may be hearing lots of other things when it is listening for you, the CSMA feature in the TNCs may prevent the PBBS from answering you promptly. Therefore, if FRACK is too short for the existing conditions, your system will automatically retry each packet. The net result again is excessive timeouts and disconnects. I suggest strongly that for working the local PBBS during the evening and weekend hours *set FRACK to 8!* That will help the PBBS during its wait for a brief clear spot between bursts of everyone else's packets.

Slow down! What's the rush? Increase FRACK when the channel is busy or when you're working through a station or digipeater in a high-elevation location. Try to understand what the systems are attempting to do.

TXDELAY

This is the length of time (the units vary on different TNCs) that your TNC will wait between the moment when it keys PTT to put your rig on the air, and when the TNC actually unlatches and sends the packet data out to the rig.

During the TXDELAY period, the TNC sends a stream of contiguous FLAG fields (01111110), until it begins the actual frame contents. Some of you may think of TXDELAY only in regard to the time it takes for your transmitter to switch on and develop power. TXDELAY must also be considered in terms of how long it takes for the other station's receiver to unsquelch and recover its full sensitivity after its transmitter shuts off. Some radios take a relatively long time between "transmitter-off" and "receiver-on."

If your TXDELAY setting is too short for the other station's receiver recovery time, that station may not be able to successfully decode the SYNC FLAG (8 bits) at the beginning of your packet frame; its system will not see a valid packet; you'll get no ACK; you retry; the other station still gets no sync; etc. The end result is lots of unnecessary retries, timeouts, disconnects, and frustration.

AXDELAY and AXHANG

If you are *not* going through a voice repeater or a series of non-packet auxiliary and link systems, these values should be left at *zero*. They are basically irrelevant in the straight digital world.

MAXFRAME

This is the number of frames (packets) sent in a single transmission by your station. You can send from one to seven. Although it may seem contradictory, in many cases MAXFRAME=1 can produce the best throughput (amount of information transferred in a given time period or session).

If you're on an empty channel (?) transferring longish files—either text or binary data—with a nearby station over a very solid

path, you can leave MAXFRAME at the default value of 4. If you have a path with a problem or two and are seeing retries due to conditions or collisions, set MAXFRAME to a *lower* value. That way, the distant end has fewer contiguous frames to decode and validate, and the channel has a bit more breathing space through which other stations can slip a packet now and then. If retries become frequent, set MAXFRAME to 1. You and your partner have a better chance of getting the ACKs back. Remember this—if the distant station decodes your packet properly and sends you an ACK, your TNC must also receive the returning ACK! It's a bummer when the other guy's good ACKs are getting trashed on the way back to you!

PACLEN

This is the maximum number of octets or bytes (characters that you type) that can be squeezed into one packet frame. The AX.25 maximum is 256 bytes. The default value is 128 bytes.

Don't get into the lazy habit of typing endless lines of stuff with never a carriage return, depending on your TNC to packetize and send the stuff after the 128th character you type. Even on the C-64's 40-column screen, it's easy to judge when you've typed between a line-and-a-half and two full lines. Type a carriage return after the last word that fits nicely before the end of the second line. That way, you'll be sending packet frames with just under 80 bytes, and the probabilities improve for your successful packet. On a busy channel, the shortest packets get the best results!

In addition to packet length, carriage returns are important in maintaining visual fidelity. Remember that just because your terminal, computer, or TNC has inserted a local carriage return when echoing data to you, it probably has not put in a carriage return for the other user. This usually results in run-on, hard-to-read text at the distant end. Some PBBSs will ignore message text if the line length before a carriage return is more the 80 characters.

On an 80-column screen, 128 characters are a bit more than 1-1/2 lines of typing. On the C-64's screen, that's more than three lines of typing. If the going gets rough judging by the retries over a lousy path, or there are lots of collisions with other stations, *reduce* PACLEN to 64 or even to 32. The shorter the packet frame's length is, the greater the probability of getting a good packet through.

Experience is showing that, on busy channels (especially with PBBSs and digipeaters), increasing FRACK and TXDELAY, while reducing PACLEN, can actually *improve* your throughput rather than degrade it!

Remember—there's nothing sacred about the TXDELAY, FRACK, MAXFRAME, and PACLEN default values. Experiment with other values and see what happens. It can only help—it will never hurt.

DWAIT

This is the length of time that your TNC will wait after last hearing data on the channel before starting the TXDELAY timer to key your transmitter's PTT line, *unless* the TNC is waiting to transmit digipeated packets. DWAIT is particularly important when working with digipeaters on a busy channel. Remember that DWAIT is affected by your TXDELAY setting, and for best results should be set at some value established in agreement with other local packet operators.

DWAIT's main function is to help prevent or reduce collisions with digipeated packets. Dr. Tom Clark W3IWI suggests the TNC timings in Table 2 to improve channel throughput when PBBSs, digipeaters, and keyboard-to-keyboard users share a common channel.

RETRIES

This is the number of times your TNC will repeat the same packet to the distant station if your TNC has not received an ACK. Good practice is to set RETRIES for the lowest number that can be effective in any given condition. The default value of 10 is reasonable for general operation. But if you're trying to force lengthy packets through five digipeaters over marginal paths in busy channel hours, RETRIES=15 (maximum number) will probably do nothing more than antagonize the rest of the troops on the channel.

"I expect to answer my terminal when it beeps—I get cranky when I see that it's merely another nonsense beacon carrying BELL signals."

Note that on some TNCs, RETRIES=0 sets an *infinite* number of retries! In the metro New York, Chicago, Miami, and Los Angeles areas, this is guaranteed to earn you a late-night visit from one of those fellas with the long coats and black leather gloves. Punishing the channel and its population with large quantities of fruitless retries is not the best way to win the local packet popularity contest.

Beacons

If the renowned anthropologist Margaret Mead were still alive, she could study the packet channel population as she did the puberty rituals of the Trobriand Islanders. Upon reaching puberty, each young male anoints himself with bright red mud and parades around the village for a month, thus advising all young unattached females of his new maturity and availability.

Judging by each week's new beacons on our local area channels—you know, the beacons that come on every two to six minutes and give us callsign, name, QTH in painful detail, and "digipeater on, buffer save to disk enabled"—new packeteers seem much like the Trobrianders. This must be a "packet puberty" ritual: "Here I am. Come and use me!"

You can't legislate common sense. Either a person has it or not. Seems some people need that beacon to reinforce their ego and make sure that the packet community at large *knows* that they have packet radio.

What could be more redundant than a beacon like those we see from stations (some of whose callsigns show them to be "old-timers") advising us regularly that they are running a "Packet Radio Communications Facility"? No kidding! It must take Dick Tracy to figure out that a packet beacon emanates from a "Packet Radio Communications Facility"! Now tell us something we *don't* know! Some of these "vigorous beaconeers" have had their callsigns used to test the operation of the LCALLS (ignore packets) routines in the TNC-2 and PK-80!

Most of these ludicrous beacon texts could be stuffed into the CTEXT file, so that the nonsense about "BUFFER OPEN—AUTOSAVE TO DISK ENABLED" would be sent *only* to the station that connects to them. But, unfortunately, that would take a generous dose of common sense and a bit of time to read the equipment manual, add two and two, and not get 22.

It's beginning to remind me of what happened to the older two-meter operators when the two-meter repeater infestation started and the air was filled with nonsense. That certainly spurred the development of 440! I wonder how long it's gonna take the technology-oriented packet people to move up to 220 and 440 and 1296 megs so that the "beacon freaks" can have these channels all to themselves.

It's so easy to find out if your buddy is running his digipeater. All you do is loop back (connect to yourself) through his station. If you get a connection, guess what? His digi is ENABLED! If not, oh well.

Are Beacons Justifiable?

In my opinion, there is very limited justification for beacons on a packet channel. The problems come from the way people use them. Here's what I mean:

Beacons are *not* inherently bad—their intended purpose is misunderstood, and they are frequently misused by newcomers. The beacon can still perform vital functions when properly written and appropriately used. This is especially true as we begin to expand into collateral or additional packet channels on two meters and on the other bands.

Understand the origin of the beacon feature—why it was provided. It really was an important option in the early 1980s when the packet-radio world was a vast wasteland and we needed efficient means of letting the world know that someone was alive, well, and available on the channel and ready for connecting. The beacon also provided an ex-

cellent source of test messages for lining up the early TNCs when there were no other means of testing the kits.

As we all know now, packet radio is *no wasteland*. In many large cities, we already have more users than our primary channel can handle most of the time. For the primary channels in metropolitan areas, the beacon function has outlived its original design intent. Beacons should be re-evaluated and tailored carefully and specifically to present (and future) conditions of channel purpose, assignment, and occupancy.

Apparently some users don't know what a beacon text will look like on the distant station's screen. They put their callsign in their beacon text, not realizing that their callsign will be displayed in the header text on almost all systems—unnecessary, redundant information.

Apparently some users don't know the default conditions of most TNCs. Nearly all of them (and I have tested five types) will boot up with DIGIPEAT enabled and will perform the digipeat function unless you tell them not to. So, why use the beacon text to advise everyone on the channel of something that can be assumed automatically?—more unnecessary information.

Some users feel the need to tell the channel that their "buffer save to disk is enabled." That's something else the rest of the users can assume. With the proliferation of the smarter TNCs like the TNC-2 types and the PAKRATTs, with smart buffers and autoconnect messages, the receiving TNC itself can provide this information *after* the user connects to it—it's not needed as part of the beacon text.

Some users feel compelled to suggest connection paths in the beacon text. Any reasonable TNC with a trace or special header function permits the others on channel to derive the beacon path when and if they need it—more unneeded data.

What is needed in a "meaningful" beacon text? Here are my suggestions: absolute brevity—minimum bytes to get the idea across; name of operator; QTH in City, State format; grid locator in XXNNnn format; special *temporary* information, such as test conditions, new operating hours, power reductions, changes in effect, and directed messages like "W2XXX PLS CALL ME URGENT"; Q-signals cleverly used, as originally intended (see Table 3); international Z-signals (available on request); and a generous dose of common sense.

What is undesirable in a "meaningful" beacon text? Anything unessential; long-winded information that never changes; "cutesy" graphics, such as lines of asterisks, parentheses, center-screen formatting (in short, save the arts and crafts for 80-meter RTTY); and ego trip and "show-off" messages.

Beacon Timing

There is absolutely no justification for sending a beacon every one, two, or three minutes. In many metropolitan areas, there's little justification for basing the beacon timing to the AFTER routine. On a primary channel like 145.01, there is no harm in an *informative* beacon every 30 minutes—let's face it, that's all the channel can handle without strangling. That's still 48 beacon messages in 24 hours! On auxiliary channels like 145.03, .05, .07, and .09, a beacon every 15 minutes will let the world know you're there. The gang won't find out any faster if the beacon is sent every two minutes.

Once a user has joined a local packet-radio club, or his station has shown up on a packet network map of his area, the rest of the local area users will know who he is, where he is, and in general everything that *they* wish to know about him and his operation. At that point, the beacon will become of less importance, and the beacon intervals can be reduced to simply indicate that the station is in fact alive and well on the channel and available for normal service.

The only constraint on the use of the beacon feature is the requirement for the generous use of ordinary common sense, lightly tempered with some patience on the part of the old packet hands, and a more tolerant, more tutorial approach to the new kids on our packet-radio block. We can't expect them to understand everything about our packet mode the day they first put their packet boxes on the air. The manufacturers' manuals are close to worthless when it comes to instructions on good on-the-air operating practices and procedures.

"Repeated attempts to log on to a PBBS that is already in use will certainly result in winning the 'Most Unpopular User of the Week' award given by area sysops."

Beaconeers and the PBBS

If you want to use a PBBS as a digipeater for your convenience, I'd suggest a bit of common sense and courtesy. For example:

Don't digipeat your beacons through the PBBS! That's not what a PBBS is all about. Digipeat your beacons through someone else. (Beacons are doubly offensive when your system sends them through a PBBS while someone else is trying to download a file or read the mail.)

If you're using the local PBBS as a digipeater, don't stick BELL commands in your stuff unless you have some legitimate reason for ringing someone's bell. I'm referring to the Control-G character. I expect to answer my terminal when it beeps—I get cranky when I see that it's merely another nonsense beacon carrying BELL signals. Baloney!

If your beacon has something important to say, like a club meeting notice, an urgent call for a contact, or anything *other* than another pointless ego trip, send the beacon through some other available digipeater.

Good Manners and the PBBS

For those newcomers who may not be familiar with PBBS operations, please be advised that most PBBSs are *not* multi-user systems, nor can they accept or handle multiple connections. This means, in plain English, *first come, first served!* If you see that the PBBS is already being used by another station when you wish to use the PBBS, you must wait your turn. Your CONNECT REQUEST sent while someone else is logged on will produce the following results:

- You will get the "(PBBS CALLSIGN) BUSY" message and a DISCONNECT.
- The station logged on to the PBBS will see a message on his/her screen stating that "W2XXX just tried to connect" or the like.
- The PBBS sysop will see the same message on the local console screen if he/she happens to be watching.
- The PBBS will issue the "W2XXX just tried to connect" to the channel in general.
- If the logged-on user station happens to be downloading a file to disk, some PBBS systems will place the "W2XXX just tried to connect" in the downloaded file just as though it were a native part of the file. The user will then have to edit the received file or program to remove the junk strings.

Repeated attempts to log on to a PBBS that is already in use will certainly result in winning the "Most Unpopular User of the Week" award given by area sysops. These packet systems, their channels, and the PBBSs are all based on the concept of the "shared resource." Wait your turn to get your share when using a PBBS. If you see the PBBS already sending protocoled packets to another station, wait until the current user has logged off, pause about 30 seconds to permit the PBBS to recycle itself, and then issue the CONNECT REQUEST.

Sorry if this all sounds like a new, "digital" version of the old two-meter "Repeater God" story, but some of the PBBS sysops have as much as $5,000 worth of computers, TNCs, radios, and antennas at your service. It's their station and their legal responsibility. Therefore, any PBBS sysop reserves the right to decide how, when, and by whom his system will be used.

Common sense is all that's required. Try some—it doesn't cost much.

"Coordinated" Packet Channels

There seems to be growing misunderstanding about the use of so-called "packet channels" (145.01, .03, .05, .07, and .09 in many areas).

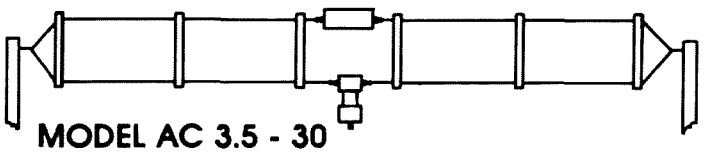
The practice of sending long programs and files between two packet stations *in direct*

connection indicates that some people may have the impression that packet channels are the *only* channels where packet radio can be used. *This is categorically false!* You can use packet radio on *any* channel on which F1 emissions are authorized. This includes most of two meters. Common sense dictates that you avoid using those repeaters whose user support groups do not desire packet communications on the repeater, as well as observing other gentleman's agreements and band plans, satellite passbands, DX calling frequencies, etc.

If two stations wish to transfer files back and forth and can make direct connection (without a digipeater or other intermediate relay mode), these stations should move off of the "packet channels" to conduct *direct* station-to-station file transfers. In that manner, the limited number of packet channels can remain free for the users who need the available digipeaters or wish to have a comfortable keyboard-to-keyboard chat or move a message in or out of the local PBBS without having to battle the intense, rapid-fire barrage of frames running between the stations involved in the extended file transfers.

It's only common courtesy to operate under the assumption that these packet channels are a shared resource. It's hard to share the channel with two guys who are running with super-tight TNC timings and completely monopolizing the channel with flying fields and frames.

I don't believe that the frequency-coordinating councils intended to imply, nor should any packeteer infer, that packet radio *can only be used* on these coordinated packet channels. This coordination was done to give the growing packet fraternity a "home" separated from the "traditional" voice simplex channels and repeater channels. It also serves as a notice to voice users who want to avoid automated stations using a 40-millisecond window to check to see if the frequency is in use.



There is absolutely *no reason* why long files cannot be transferred between two stations in direct connection using the simplex channels available throughout the bands—with a bit of care, courtesy, and common sense. You *must* listen on the intended operating channel *before* transmitting. If an SSB or FM voice contact is in progress, the old rules still apply; don't knowingly dump tons of packets on top of a voice communication in progress.

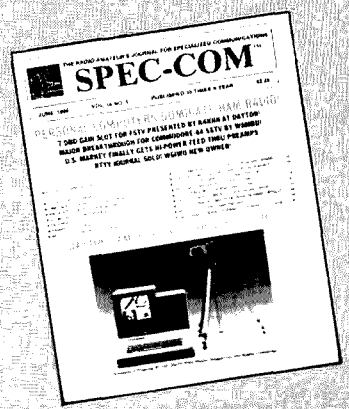
Advanced technology will never be a replacement for courtesy and common sense. The latter talents are sometimes more important than the former.

A Wee Packet Philosophy

It's really up to us to teach each other and help the mode grow in orderly fashion, rather than merely criticize others. Those of us who are fortunate in having more experience and understanding more about packet radio and its unique qualities have a real moral and technical obligation to serve as mentors towards those who know less but want to know more. ■

CONTINUOUS COVERAGE
FOLDED DIPOLE ANTENNA

MODEL AC 3.5 - 30
(formerly Model 370-15)



- Fully Assembled • 52 OHM • Only 90 feet long
- SWR less than 2:1 from 3.5 thru 30 MHz. Average SWR 1.4:1
- Will handle 1 KW power (2 KW PEP)
- Can be installed as flat top, sloper, or inverted "V"
- Used the world over in government & commercial communication installations
- Ideal for all operations - amateur, commercial, MARS - any frequency from 3.5 - 30 MHz

PRICE $167.50
PLUS $3.00 Shipping and Handling

Precision Packet Tuning

Build the ultimate digital tuning indicator for packet or RTTY.

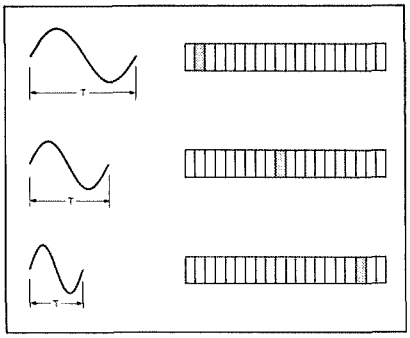

Fig. 1. Appearance of display for a single tone.

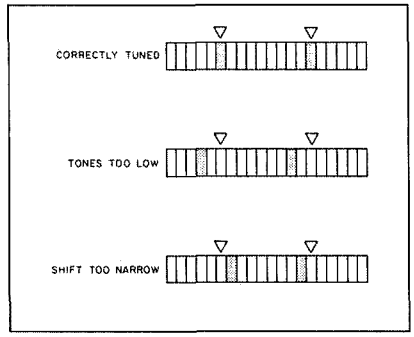

Fig. 2. Appearance of display for AFSK signals.

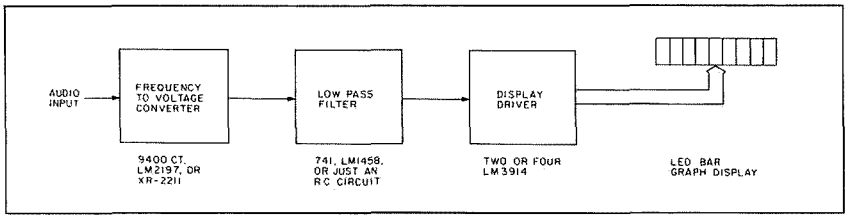

Fig. 3. Block diagram of most analog tuning indicators.

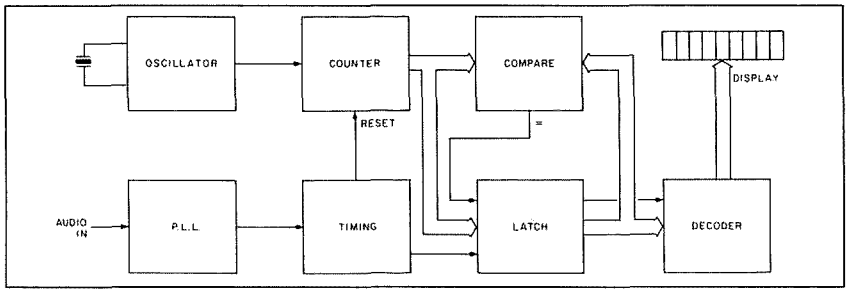

Fig. 4. Block diagram of digital tuning indicator.

Some aspects of RTTY have changed quite a bit during the last 40 years. Toroids, vacuum tubes, and Model 15 Teletypes® have been replaced by integrated circuits. Other things are still the same. Most people are still using 60-word-per-minute Baudot code. And, judging by my observations, most people are still using signal-strength meters, dual-ellipse patterns on oscilloscopes, or just random fiddling with the dial to tune in signals. Two stations conversing are rarely right on the same frequency.

These traditional techniques may be adequate for old-fashioned RTTY, but HF packet is *much* more difficult! Instead of 5-minute monologues, you must catch 1-second bursts on a channel often shared by several concurrent conversations. If you miss a few bits, you don't just get some garbled characters in part of a continuous stream. The whole packet is discarded and you don't know how long it will be until the next one is sent. Tuning, therefore, is more critical. For best results, you should be no more than 20 Hz off frequency. Forget about receiving anything if you're 50 Hz off.

A few years ago, a new type of RTTY tuning indicator appeared. It uses a light-emitting-diode (LED) bar-graph display to indicate the frequency of the incoming audio signal. Fig. 1 illustrates the basic idea. Each LED segment corresponds to a small range of audio tones, typically around 10-to-25-Hz wide. As the audio frequency increases, a different segment farther to the right is activated.

When an audio-frequency-shift-keyed (AFSK) signal is present, two bright spots appear along the display—as shown in Fig. 2. You can see instantly if the tones are too low or too high, and if the shift is correct.

The first device of this type (that I know of) was the Toni-Tuna.[1] (Fig. 3 shows a block diagram.) It uses a frequency-to-voltage converter, a low-pass filter, and some 3914 bar-graph display-driver chips. Recent products such as the HAL SPT-1[2] and AEA TI-1[3] are minor variations of this circuit. The TAPR Tuning Indicator[4] is a little different in that it has a single dot that moves with the average of the minimum and maximum peak frequencies. This has the unfortunate property of producing the same appearance for a steady carrier as for an FSK signal of any shift.

The simplicity and low cost of these analog devices are attractive, but they have some serious shortcomings. To calibrate them, you need a very accurate source of tones such as a signal generator and digital frequency counter. Adjacent LED segments correspond to frequencies that differ by only about 1%. Would you trust a cheap analog circuit to stay well within this tolerance with temperature changes, voltage fluctuations, and component aging?

The TimeKit Blinky[5] looks similar on the outside but works on a much different principle. It has six bandpass filters centered at 1.2, 1.5, 1.7, 1.9, 2.1, and 2.3 kHz, each driving a different LED. With each LED representing at least a 200-Hz range of tones, this has nowhere near the accuracy required for packet.

To overcome the weaknesses of the analog circuits, I built a device with the same type of display but with mostly digital circuitry behind it[6] (see the block diagram in Fig. 4). First, a phase-locked loop (PLL) locks onto the strongest frequency in the audio signal. A crystal-controlled counter measures the period of each cycle, and the corresponding LED segment is activated. The digital approach is far more accurate and does not require calibration. Even with the cheapest crystal, temperature variations, power-supply fluctuations, and component aging, the accuracy is still at least an order of magnitude better than the display resolution.

The digital approach also has a novel feature that really helps clean up the display appearance for noisy signals. The LED numbers for the current and preceding audio cycles are compared. The display is disabled when they are different. Thus, there is less of a tendency to get a blur as the input frequency is changing. The display comes on only when the frequency stays put for a while. The result is a much sharper display for noisy signals.

This article describes an entirely new circuit that operates on the same principle but has the improvements listed below:

1. Fewer chips.
2. Operates on single voltage supply.
3. Uses a cheap and readily available colorburst crystal instead of a different custom crystal for each frequency range.
4. More flexible mapping of the frequency to display segments.
5. The display is blanked with no input signal.
6. More digital processing of the signal to clean up the display appearance.

Table 3. Portion of EPROM contents for blanking when frequency changes. Locations causing display to be enabled are underscored.

Circuit Description

In the upper left corner of Fig. 5, the audio enters U1, a PLL, which tries to track the audio signal. Pin 5 is low when U1 thinks it is locked onto something. The XR-2211 has no voltage-controlled-oscillator (vco) output available outside the chip, so I used U2 to extract it from the timing capacitor.

During most of each audio cycle, U5B and U6 are busy counting away. At the end of the audio cycle, U3 controls the following sequence of events: clear frequency divider (U5A), causing counter (U5B and U6) to stop; enable the EPROM (U7); wait awhile for the counter to settle down; grab the

Table 4. Hysteresis added to prevent flickering at the boundaries. Locations differing from preceding figure are underscored.

EPROM output in the latch (U8); clear the counter; and start counting for the next audio cycle.

The EPROM maps the count, proportional to the audio cycle period, into the appropriate LED segment. It also does a few other little tricks as we'll see later. Finally, U8 and U9 drive the LED display.

Construction

Fig. 6 contains the pattern for etching a PC board for those who wish to make their own. Fig. 7 contains the parts placement guide. Note that six jumpers are required. One of them has one end in either the JP1 or the JP2 hole depending on the input frequency range. If you have an extra 200 milliamps of 5 volts available, U10 can be bypassed. Otherwise, the unit can be powered from your 12-volt

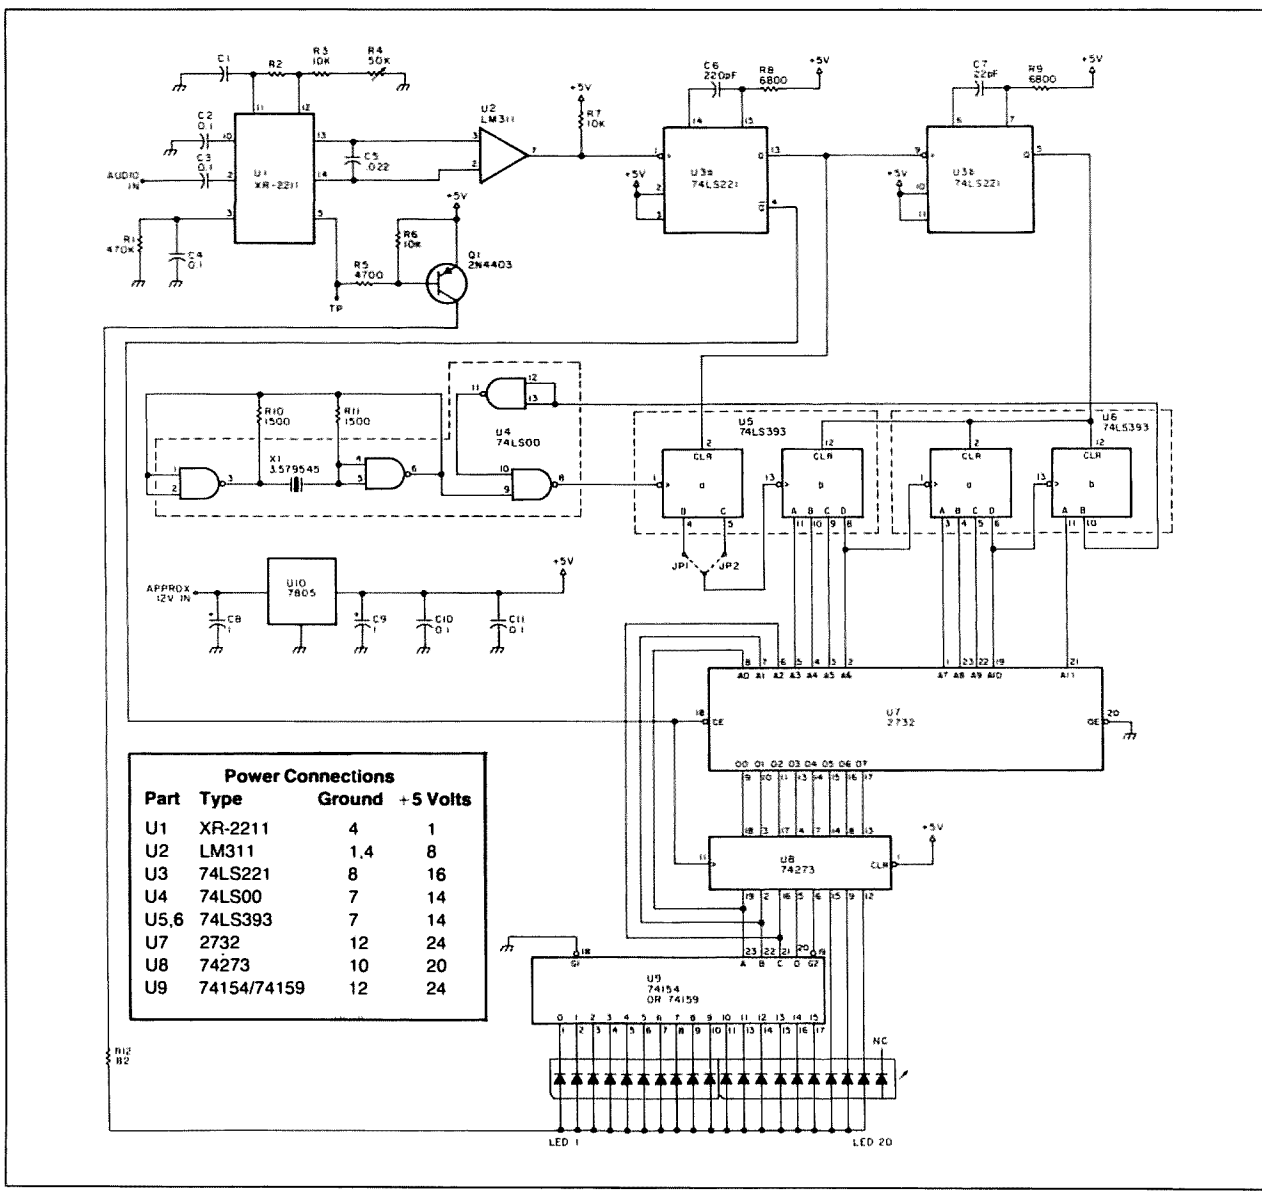

Fig. 5. Schematic.

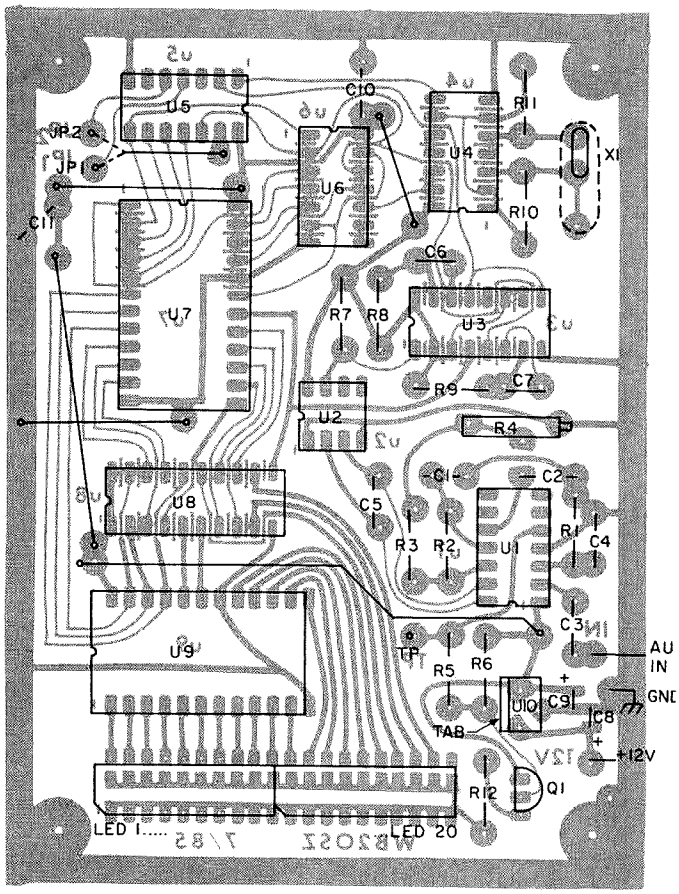

Fig. 7. Parts placement guide.

transceiver supply, or a separate supply can be constructed (Fig. 8).

The PC board has an extra hole, so a crystal in either an HC18/U or an HC33/U holder can be used. There is also an extra row of holes, so the LED displays can be mounted flat on the board or on right-angle sockets. I constructed a 40-pin right-angle socket from three 16-pin right-angle sockets, using a saw, a file, and some glue. Some may wish to build a larger display with different colors of discrete LEDs.[7] A few people wrote to me and reported that it makes a more dramatic display.

Mostly 74LS parts were used instead of regular TTL, for reduced power consumption. U8 and U9 are exceptions, because more current-sink capability is required to drive the display. Pay particular attention to the orientation of the ICs; they go in all different directions. Be sure to use mylar™ and mica capacitors where indicated in the parts list. Disc ceramic capacitors are very unstable and should not be used in timing circuits where accuracy is important.

The EPROM

In this section, I'll try to retrace the thought process that went into generating the data for the EPROM. It can get rather tedious. If you get lost, just skip to the next section.

First, let's look at the required EPROM output for selecting each of the LED segments. The four high-order bits (07–04) from the EPROM are enable signals. A logic zero at bit 7, 6, or 5 activates LED segment 19, 18, or 17, respectively. When bit 4 is zero, U9 selects one of the remaining LEDs based on the four low-order bits.

Thus, LEDs 1 through 16 are selected by the bit pattern 1110nnnn, where nnnn is 0000 through 1111. LEDs 17, 18, and 19 are selected by 1101xxxx, 1011xxxx, and 0111xxxx, respectively, where xxxx doesn't matter. Note that the low-order bits in the middle column of Table 1 continue to be incremented for a reason to be explained later. The final column is the same except all the enable signals have been set to 1. These are for cases in which the display should be blanked. The low-order bits still contain a hint as to which LED would have been on if the display hadn't been blanked.

The next step is to fill in the proper EPROM locations with values from the preceding chart. Let's take the 1600/1800-Hz tone pair as an example. I decided arbitrarily that LEDs 5 and 15 should correspond to these audio frequencies and placed small triangular pieces of plastic tape above them on the display.

When the crystal frequency is divided by 8 (by U5A), divided again by the audio input of 1600 Hz, and rounded to the nearest integer, you would expect a count of 280. Actually, a slight correction must be made to compensate for the clock cycles not counted while the one-shots are active, so the real count is 279. Similarly, a count of 248 is obtained for 1800-Hz input. The EPROM locations for a count of 279 are filled with the pattern to activate LED 5. The bit pattern for LED 15 is placed in locations for a count of 248. From here, some interpolation and extrapolation was used to fill in other nearby locations (Table 2).

After repeating the process for four other

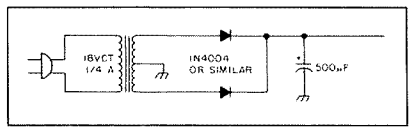

Fig. 8. Ac power supply for use when roughly 12 V dc is not available.

Modem Tones	Dial for USB	Dial for LSB
1070/1270	14,100.13	14,102.47
1600/1800	14,099.60	14,103.00

Table 5. Dial settings for USB and LSB.

common tone pairs, I plotted the data to make a visual check and made some more minor adjustments. The result is in Fig. 9. All of this was done before the circuit was built.

By now you're probably wondering why there are eight memory locations for each count. The next evolutionary step was to add blanking while the input frequency was changing. The goal was to enable the display only when the same LED was selected for two consecutive audio cycles. The result is bright spots where the frequency stays still for a while and dimming of the blur as it moves around.

Note that the three low-order bits of the previous LED number are used as the low-order bits of the EPROM address. Table 3 illustrates the new contents. Hexadecimal notation has replaced the binary to make the chart more compact. For a count of 278 through 280, LED 5 is the desired result. Note, however, that the display is enabled (output e3) only if LED 5 or 13 was selected the previous time. My original circuit used a 7485 to compare the low-order four bits of the LED number. In my observations, it looked as if the PLL couldn't move that far in one audio cycle; so, in practice, comparing only the three low-order bits is adequate. Doubling the EPROM size and comparing the four low-order bits would be a worthwhile experiment, especially if the PLL was modified to track higher data rates.

Finally, a tone right on the edge between two LED segments would result in flickering. I added a small amount of hysteresis, so a frequency right at a boundary would stay with one LED or the other (Table 4).

Fig. 10 contains a complete annotated copy of the EPROM data in Intel Hex Format. Each line contains a colon to indicate the beginning of a record, two hexadecimal digits for the data byte count (always 08 in this case), four hexadecimal digits for the starting address, two zeros for the record type, a variable number of data bytes, and two hexadecimal digits for a checksum. Anything preceded by an exclamation mark is a comment. These comments will probably have to be removed before feeding this data into most EPROM programming systems.

The Weak Link

The weakest link of the whole system is the phase-locked loop. Following the spec sheet and application notes, I first tried 150k and .0047 uF for R2 and C1. This resulted in very poor tracking of the audio signal. The loop was under-damped, resulting in excessive overshooting of the input frequency. After recomputing C1 for critical damping, the vco was rather sluggish about tracking shifts in frequency.

After lots of experimentation, 47k and .0025 uF seemed to be a good compromise for several tone pairs. All the experimentation up to this point had been done with a locally generated 300-baud AFSK signal. It did not work well at all with real signals from a radio.

After more tweaking, testing, and fiddling,

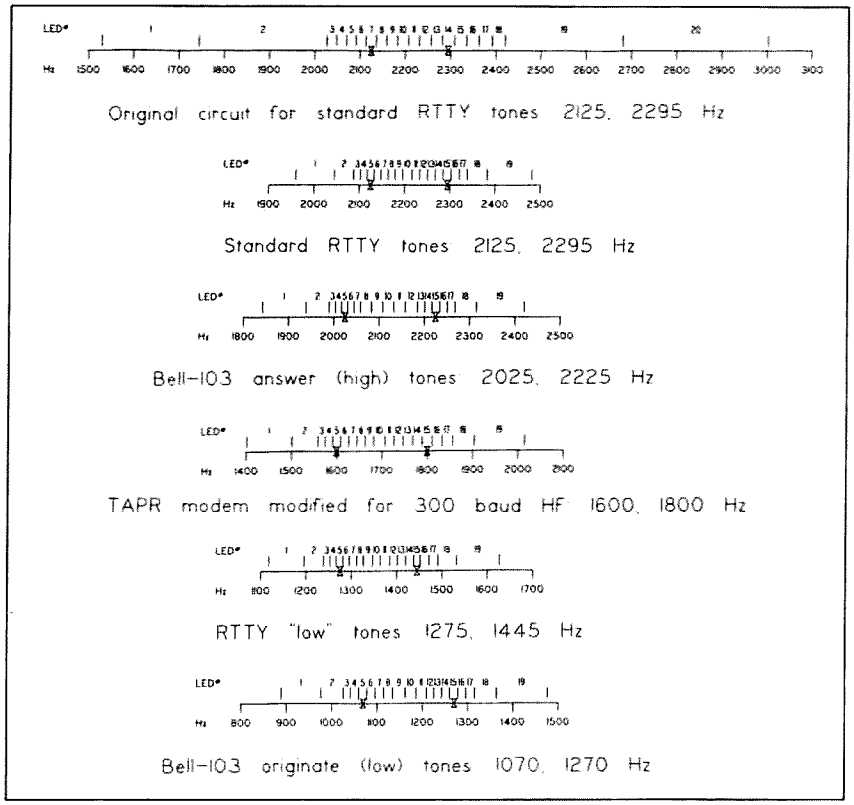

Fig. 9. Frequency ranges of LEDs.

Parts List

C1	.002-uF mylar or mica
C2, 3, 4, 10, 11	0.1-uF disc ceramic
C5	.022-uF mylar
C6	220-pF mica
C7	22-pF mica
C8, 9	1-uF tantalum
LED1-20	Two 10-segment LED bar-graph displays such as MV57164
Q1	2N4403 or similar PNP
R1	470k
R2	120k
R3, 6, 7	10k
R4	50k multi-turn pot
R5	4,700 Ohms
R8, 9	6,800 Ohms
R10, 11	1,500 Ohms
R12	82 Ohms
U1	XR-2211, FSK Demodulator/Tone Decoder
U2	LM 311, Comparitor
U3	74LS221, Dual monostable multi-vibrator
U4	74LS00, Quadruple 2-input NAND
U5, 6	74LS393, Dual 4-bit binary counter
U7	2732, Erasable Programmable Read Only Memory (Available for $8 from author. Be sure to specify one of the five tone pairs desired from Fig. 9.)
U8	74273, Octal D-type flip-flops
U9	74154 or 74159, 4-line-to-16-line decoder
U10	7805, 5-volt regulator
X1	3.579545-MHz color-burst crystal
misc.	Heat sink for U10 Socket for U7 Optional right-angle sockets for LEDs

subjective decisions about display cleanliness, and playing the same recording of packet signals over and over, I finally settled on 120k and .002 uF. R2 basically sets the bandwidth. Too much bandwidth (smaller R2) makes the PLL overly responsive to the noise. Too little makes the PLL too sluggish about following the desired signal. C1 sets the damping factor. If CI is too big, the vco frequency overshoots and rings when the input frequency suddenly jumps. If too small, the PLL doesn't follow the changes fast enough.

Note that I was optimizing for 300-baud operation. A slightly larger resistor or smaller capacitor would probably improve performance for lower-speed RTTY.

Adjustment

Connect the audio input to ground. Also connect the test point (TP) to ground. Adjust R4 until LED number 10 is lit. Disconnect the two points connected to ground earlier. That's all! Never worry about it again. Any minor drifting of the PLL center frequency will not affect the accuracy of the device.

Installation

Fig. 2 shows the ideal case of a perfect signal coming right out of a signal generator. A real signal from an HF transceiver has plenty of noise and distortion that will cause the cleanliness of the display to deteriorate. If you connect the tuning indicator directly to the speaker, a pleasant display will be obtained only for a fairly strong and clean signal. For more typical signals, the audio must be cleaned up.

All good quality RTTY terminal units (or packet modems) start with a bandpass filter to select the frequency range of interest and attenuate the rest. After this bandpass filter is the proper place to connect the tuning indicator. If you are using a TAPR TNC-1 or one of the many clones, obtain the signal from pin 1 of U20. This is the output of the low-pass filter after the switched capacitor bandpass filter. If you're in doubt as to where to make the connection to your system, send me a copy of the modem schematic and an SASE.

(Note: Simple PLL demodulators such as this enjoyed a brief popularity on RTTY a few years ago. Soon, most people realized they just didn't work very well with noisy HF signals and went back to the good old-fashioned designs with separate mark and space filters. The packet crowd had to rediscover this fact, and only recently have packet equipment manufacturers begun to offer better quality modems for HF use.)

HF Packet Frequency Specification

Suppose you were having a RTTY QSO with someone in England. Your transceiver's display says 14,085.00 kHz. What would be displayed on his transceiver? Probably 14,081.43—more than 3.5 kHz different! How can this be?

Almost all amateur HF RTTY uses 170-Hz frequency shift keying (FSK). This is usually produced by generating an audio-frequency-

```

shifted signal and feeding it into an SSB transmitter. By convention, the *higher* radio frequency is the "mark" frequency (idle or data "1"). In the United States, audio tones of 2125 and 2295 Hz are most common. The *lower* audio frequency is the mark tone. To make this correspond to the higher radio frequency, the LSB mode is used. In some other parts of the world, audio tones of 1275 and 1445 are more common. In this case the *higher* tone is mark so USB is used.[8]

Both stations are operating on the same frequency, but their transceivers indicate different frequencies. How can frequencies be described for skeds, nets, or other purposes? The common solution is to specify the radio frequency of the mark state. Taking the earlier example, 14,085.00 − 2.125 = 14,082.875. For the other station, 14,081.43 + 1.445 = 14,082.875, which is the same. Each station performs the required calculation for its particular audio tones and USB/LSB mode.

We have a similar problem with HF packet, which has suddenly become very popular. Like RTTY, it is usually transmitted by feeding an AFSK signal into an SSB transceiver. I've heard of people using 170-, 200-, 600-, and 1000-Hz shift, but 200 seems to be by far the most popular. Some people are using Bell 103 type modems with 2025 and 2225 tones (or 1070/1270). Others are using modified TAPR modems with TAPR's suggested 1600- and 1800-Hz tones. Many are using LSB. Some may be using USB. These are all compatible as long as the shift and baud rate are the same. Packet radio doesn't really have absolute "mark" and "space" states. The encoding scheme uses transitions and lack of transitions to convey a 0 and 1, respectively. Therefore, your signal can never be "upside down," as is possible with RTTY.

How would you set your transceiver to meet another station at 14,101.3 kHz? From the previous discussion, it should be clear that several packet stations all with the same numbers on their displays could be sending signals on significantly different frequencies. As with RTTY, the obvious solution is to specify the actual radio frequency rather than the dial setting. Each operator would then make the necessary adjustment for his particular audio modem tones and sideband setting.

Should the higher or lower frequency arbitrarily be picked as the signal frequency? As mentioned earlier, there isn't one frequency that is the "mark" or idle state. It seems to me that using the midpoint between them would make the most sense. When using USB, subtract the average of your modem tones from the signal frequency to get the dial setting. When using LSB, add, instead. Using 14,101.3 again as an example, the settings in Table 5 would be used.

Conclusion

Just so no one is misled, I'd like to reiterate the fact that the display will not look like the ideal case in Fig. 2 unless you connect the tuning indicator to a local AFSK generator. The various types of noise and distortion introduced by the HF radio link will cause some blurring of the bright spots and random flickering in other LED segments.

And now the big question: Why use this circuit instead of the simpler analog variety? The much greater accuracy (without any calibration required!) and greater flexibility of the digital approach sound great, but how do they work under actual operating conditions? To find out, I breadboarded an exact copy of one of the commercial products mentioned earlier to make a side-by-side comparison. With some 20-meter RTTY, there wasn't a lot of difference.

Next I located some 300-baud packet activity, and I was very pleased with the results. My circuit produced two very distinct bright spots, with some smearing across a few LED segments, and a little random flickering all over from the noise. Overall, the display had a good contrast, and it was very easy to tune in signals within 10 or 20 Hz. The commercial unit clone had a solid blur across most of the display. Some spots close to the ends of the blur were brighter than the rest, but there really wasn't much contrast. ■

BUILD THE KIT

A complete kit of parts, including a high-quality double-sided printed circuit board, is available from Valley Electronics. The kit version is slightly different from the unit presented in this article; a larger EPROM is used which covers two frequency pairs, and several cosmetic changes have been made to the PCB.

Order Number	Description	Price
88601	Digital Tuning Indicator kit	$79.95
88602	Kit without enclosure	$72.95
88603	Semi-kit—PCB and EPROMS only	$22.95

All prices include shipping and handling.

Send your check or money order to Valley Electronics, PO Box 1101, Hillsboro NH 03244.

Seeing Packet Radio With Different Eyes

The Versabraille II system allows blind hams to get connected.

A man sits with his hands resting lightly on his plastic-like display, his TAPR TNC-2 by his side, waiting for his first real contact on packet. Finally, it comes through! He races his hands across the display with eager anticipation of knowing who it is! He sees "CONNECTED TO N7ERZ." He has finally reached his goal in amateur radio—to be able to communicate with other hams through the latest and greatest digital communication mode.

Hello to all of you fellow packeteers. I have written this article to tell you of a recent development for the blind regarding this new mode of digital communication, known by all of us as packet radio. Through the latest computer technology, Telesensory Systems, Inc., has enhanced character-oriented communications for blind users with its Versabraille II system. The system is both a word processor and a communications terminal. Its great flexibility allows for easy use with almost any TNC. It has a disk-based operating system for easy and fast access. I'll first take a look at the technical aspects of the Versabraille II before relating it to packet.

Photo A. The author and AG7H demonstrate packet-by-feel.

The computer is smaller than you would expect: 15" x 10" x 3", and its approximate weight is 10 pounds. The display is the strip just above the keyboard. It is only 20 characters wide, not quite the typical 80 columns offered by screen monitors. The 120 pins that make up the output serve as the link to the outside world for the blind user by means of touch. The pins are displayed in a typical braille-cell formation. The braille cell consists of six dots, which make up all letters, numbers, punctuation, etc. The pins move up and down, much like a dot-matrix print head.

But wait, if you sit down and try to figure out how many combinations you can have with six dots, you realize it is not nearly enough for the wide range of control characters and higher ASCII values that are used in packet communications. Therefore, the Versabraille II uses an outstanding translation program that allows the blind user to use shifted and chorded characters (one with which the space bar is simultaneously depressed along with its braille character) to produce all 128 standard ASCII values.

As for the brain of this machine, the Versabraille II system uses a CMOS Intel 8085 CPU and a 96K memory system. The user has 32,752 bytes available; the rest of the memory space is used for ROM program storage.

Now we know how the braille is shown. But how does one put characters into it? This is done by the keyboard just below the display. It is a rubberbrane-type keyboard. This is very nice, for it allows for almost silent typing. Twenty-four keys make up its foundation. Six of these are used to produce the six braille characters. To the left of these keys is an additional set of 12 keys, the numeric keypad. These keys are used for certain editing features and for fast numeric input. Just slightly above the braille display and to the left are the cursor control keys. Since the computer is menu-driven, these keys select menu items. They are also used to

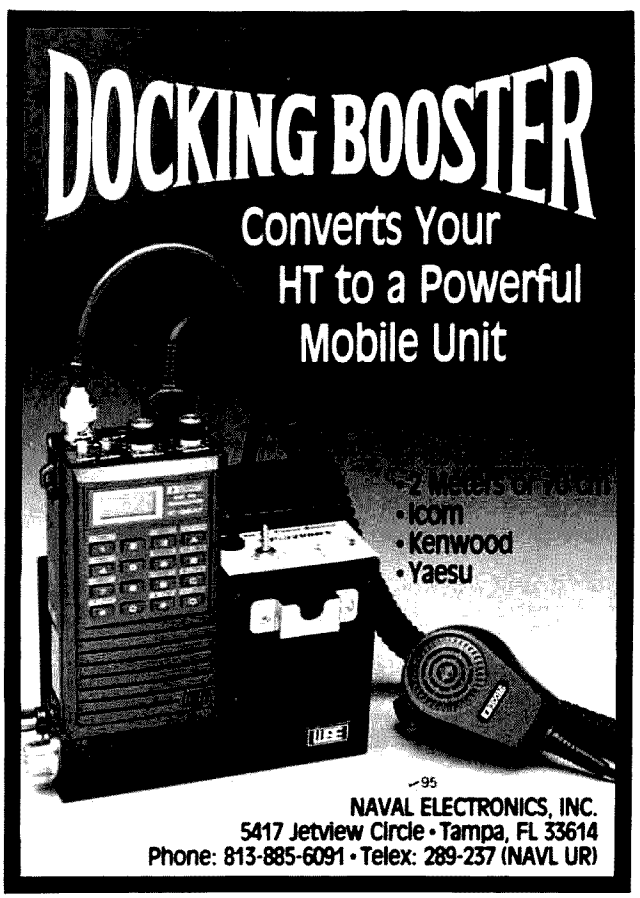
move a page of text through the 20-character window. And then, of course, there is the space bar.

On the back panel, there are two standard RS-232 interface ports, one for DTE (data terminal equipment) and the other for DCE (data computer equipment). This is the place where a TNC is connected to the Versabraille system. The braille computer has a standard female 25-pin connector, so I cabled it and my TNC-2 together by using a double-male cable. That is all the interface takes as far as hardware is concerned.

The computer can be configured to connect to a number of different types of devices, so care must be taken when setting all the parameters. Baud rate, data bits, stop bits, duplex, parity, device control character input (DC IN), device control character output (DC OUT), DTR, DSR, CTS, and RTS are the basic parameters that most computers deal with. Many other parameters control the way the Versabraille's display translator will interpret incoming data. After all parameters are set correctly, communication with the TNC is possible.

Versabraille and the TNC

I knew that my Versabraille computer would work fine with a TNC; the only thing I lacked was a TNC. Where would I get one? How? The answer came soon after I attended the annual meeting of Tucson Amateur Packet Radio, otherwise known as TAPR. I gave a demonstration of braille packet there, using a friend's TNC along with the Versabraille II. Little did I know that this demonstration would produce a big return on the investment of my time and effort. I was nearly speechless when I received a call from a very good friend who started me in all of this packet venturing. He exclaimed, "Jeff, your dream has come true. TAPR is donating a TNC-2 board to you!"



My heart leaped with joy after hearing the news, but deep inside it still did not seem real to me. When Lyle Johnson, President of TAPR, arrived one afternoon with my TNC-2 in hand, I finally knew that the door had been opened for new and exciting challenges. It was like a new beginning of the hobby—as though I just got a new ticket. TAPR wants me to develop interface software so that other blind operators can easily participate in packet radio.

The Versabraille comes with a terminal-emulation package, which connects the display and keyboard to the serial port. I can read the display fast enough to keep up with packet conversations at 1200 baud. But soon after becoming quite experienced with the board, I found that I wanted to communicate at a faster baud rate between the braille computer and the TNC. The problem is that at 9600 baud, the braille cells would just jump out of my reach, requiring me to constantly scroll through the 9K data buffer. One of my first goals is to write a program to remove the callsigns from monitored text, to speed up my reading.

But overall, no big problems have arrived. Many people have asked me why I use braille, why not just use a synthesizer. This may be a much cheaper route to take (a complete Versabraille system costs about $6,000), but after having some experience with packet using a voice synthesizer, I find it to be quite inadequate for such high-speed communication. It takes away the realism of some of packet's most outstanding features. Some of the technical data files on bulletin board systems are not easily "spoken"—a network map, for example. If you are interested in technical information on interfacing a TNC to your synthesizer, please contact me.

These two ways of using packet radio for the blind are just a beginning. Our growing technology promises more and exciting possibilities for all. If any of you would like more information regarding the Versabraille II system, please contact me. I would be happy to share ideas with you. Let us all put our heads together and tackle this new venture. Who knows, since the Versabraille II is completely programmable, the possibilities are almost endless. Remember, feeling is believing.

I would like to thank the man who made my dream reality—Ron Bates AG7H. If it were not for him, this whole venture would still be a dream. He has also helped with technical guidance regarding the hardware interfacing of the computer and the TNC-2. Thanks again, Ron. ■

So You Want To Be A Sysop?

It's not as easy as it looks.

Nothing has more potential for adding to a packet network than a packet bulletin-board system (BBS). On the other hand, nothing can cause more trouble for a packet network than a BBS. The impact—good or bad—is determined by the skill, planning, and investment of time and funds of the system operator (sysop).

This article describes some of the trials, tribulations, frustrations, and rewards of being a packet BBS sysop. Although written primarily for those considering setting up a BBS, it will also be useful to those who use the BBSs—both to improve their skills as users and to give them some idea of what a sysop has to do to keep the system operating.

Decision Time

Becoming a packet BBS sysop requires a lot more than buying a computer, wiring it up to a TNC, throwing in a couple of disks, and dialing 145.01 on your rig. In many areas where packet is growing at an amazing rate, frequency time is becoming a valuable commodity and a badly operated BBS can do considerably more harm than good.

Before you embark on setting up a BBS, some planning is in order. You have to look at the packet activity in your area and decide how you can best enhance it with your BBS. The following are several things to be considered:

What user group are you serving?

Who is going to be served by your BBS? What need is there for the system you want to establish? If you are going to be the only system in your area, the answer may be obvious. If you represent a certain group of hams who will use it, that's easy, too. But if you already have one or more local BBSs, what is your system going to add? Are there people out there who need your system? What are they looking for? Is there already a good mail/message service? Do you have access to information that others don't have? Do you have HF equipment that will let you set up a gateway?

Sit down before you start and map out the objectives of your station. It will help you decide how to configure and operate it.

What frequency is best?

What frequency (or frequencies) are you going to use? Where is most of the packet activity currently located? If you set up on the main frequency, are you going to increase the traffic unbearably? Are there other BBSs on that frequency that operate frequently? If so, there's a good possibility that you'll spend most of your time colliding with each other and nothing will get through. Maybe the best

Photo A. Typical WØRLI/WA7MBL BBS and gateway station. The station includes an IBM-PC clone, two TNCs, a VHF radio, and an HF radio. This is WB6KAJ-1, run by Lee Dusbabek.

Photo B. Closeup of the station pictured in Photo A. The center box is the AEA PM-1 HF modem. Many HF stations are discovering that a modem optimized for HF operations makes a big difference in the number of packets heard without retries. Modified RTTY TUs have also been used with success. The modem included with most TNCs is either a generic PLL-type design or a modem chip designed for telephone use. In some cases, performance of these modems on a noisy HF link is marginal.

thing is to find another frequency and give local users an alternative.

How are you going to forward mail to other BBSs? What frequencies are now used in your network? Can you access those frequencies while operating on others? Do you need to invest in a second TNC and rig to let you forward on one frequency while handling most of your users on another?

Is there a packet frequency-coordination plan in effect for your area? If so, does your planned operation agree with those allocations? Have you notified the frequency-coordination group that you want to put up a BBS? Do you have to?

What services are you going to provide?

Packet radio BBSs can provide a number of different services to their users. What services are you going to provide to yours? I'll discuss the options later in this article.

Being a Good Sysop

There are several things to consider before taking your checkbook in hand and wandering off to the nearest computerfest. When you put a BBS station on the air, you're taking on a responsibility to the other BBSs and packet users in your area. You're going to put a computer, which can blast out packets at a fantastic rate, on a scarce frequency that others are trying to use for their own communications. You're going to make a system available that, with poor planning on your part or because of an uninformed user, can virtually block a frequency from other use. In my view, you have taken part of a resource that belongs to others, so you have to give something back to make it an even trade.

There are a number of things that I believe a sysop has to do to provide a positive contribution to a packet network. Some of these are:

Enhance, not harm, packet communications.

Make sure that you operate your BBS so it enhances the capabilities of the network. This means conserving precious frequency time. Don't let your BBS spout off a 10-line greeting to everyone who connects. Don't send a 7-line beacon with your name, call, location, and last connect date. Keep your prompts, menus, and commands as short as possible. Remember—while you're sending a 10-line log-on message, someone else is waiting on the frequency for a response from the packet he just sent to his friend across town.

Also, be sure that you have the proper TNC settings for BBS use. I'll discuss these settings later on. Keep in mind that with improper TNC settings, a computer can tie up a frequency and allow *nothing* else to get through. If you do this too often, you'll wind up being hated by every packet operator in your area. Realize that on a common frequency, the BBS should have *lowest priority*.

Deliver the mail.

When you put up a BBS that supports user-to-user messages, you're inviting users to place their traffic there and you're promising

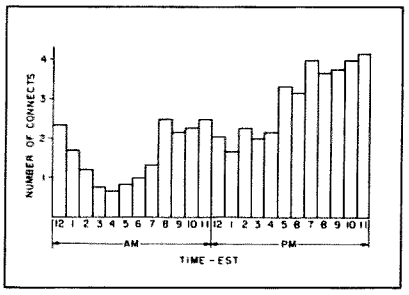

Fig. 1. Most BBS systems are up 24 hours a day. This graph shows the average number of connects by time of day at WB2MNF in March of 1986. The average connect time was 7.7 minutes.

to make your best effort to deliver it. You aren't the U.S. Postal Service, but you shouldn't entice users to leave mail on your system and then not make sure that it gets delivered.

The BBS has to be available when people want to use it. In my experience, this means 24 hours a day, every day. If you decide to put your BBS up during the day, but take it down at night when you need the computer, you'll prevent mail that users have placed there from being delivered. Part-time BBSs aren't effective—people can't use them reliably. If you want to be a good sysop, you have to dedicate a computer to the BBS. This may not mean that you can't use it for something else at the same time—I'll talk a little later about using multi-processing programs on the PC BBSs to let the computer do double duty.

Unless your users are only going to place messages to other local users on your BBS, you have to find a way to deliver messages to those out of your coverage area. In many areas (EASTNET, for example), there is a sophisticated network of forwarding arrangements established to efficiently move mail into and out of the area, as well as handling mail passing through. Any BBS set up in that network that is not coordinated with the other stations can cause major problems for the other stations by dumping mail into the network that the network doesn't know how to deliver. This BBS could also deny its users access to the rest of the network by not participating in coordinated forwarding. Unless you're the only BBS within range of your station, you *must* coordinate mail forwarding with the other BBSs.

Maintain your system.

Keeping a BBS on the air requires a lot of maintenance. Many sysops spend at least an hour every night reading mail, untangling the mail file, removing outdated messages, installing new versions, etc. New versions may crash, which can take two to three hours to fix. Hardware fails, too, and you have to do a certain amount of hardware maintenance. If you don't do this, you won't be able to serve your users properly.

Add something to the information.

Generally a BBS fills up with reasonably good information supplied by users.

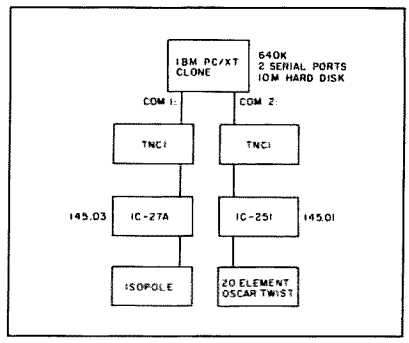

Fig. 2. The BBS system at WB2MNF.

Since you have access to the BBS any time you want it, though, and since you can transfer data faster than anyone accessing it over packet can, it behooves you to add to the information on the BBS. Maybe you're a CompuServe user and can get the *W5YI Report* from HAMNET. Perhaps you can get the useful messages from DRNET, or can post the Keplerian elements for OSCAR. You ought to find some way to add to what your users post.

Be ready to answer questions.

Since the BBS is always there for someone to use, and you obviously know something about packet radio or you couldn't have set it up, don't be surprised if you start getting questions from new users (or old ones) about everything under the sun. Expect your phone to start ringing at least once a week. Expect to see four or five messages a day from users wanting to know about anything at all. Be ready for this and find your own sources for information.

Set a good example.

Whether you like it or not, a BBS takes a high profile in packet activity. It's always on the air and people see it a lot. It is usually the first thing a new user sees. If you're using improper TNC settings (too short a DWAIT, too long a TXDELAY, too many BEACONs, etc.), you're encouraging others to do the same. Make sure that your station is set up properly. It'll help other people get theirs right.

Software Considerations

Any computer system is composed of two parts—the software and the hardware. With most applications, the software comes first in determining the configuration of the system, and the hardware is selected to fit the software. Packet BBSs are no exception.

There are certain factors that you should consider when you select packet BBS software. Packet has some special capabilities that can be utilized to enhance the BBS operation. There are also some things about packet that differ substantially from telephone BBSs, making the latter generally unsuitable for packet use.

First, in packet the caller is identified from the connect message. The BBS knows who you are from the beginning—you don't have to identify yourself. This enhances several

BBS capabilities—message handling, logging, etc. BBSs should use this fact.

Packet radio is by nature a nonsecure medium. Everyone sees everything that is transmitted over the air—there's no such thing as a "private" message. It's useless to use different levels of password-protected access to keep the system secure because packet BBSs generally have only one level of access that's available to anyone who logs on. For this reason, the BBS must be designed to allow almost anyone to connect, but prevent them from doing anything that they shouldn't.

Packet transmissions are virtually error-free because of the AX.25 protocol. Thus, there's no need to add an additional protocol (like XMODEM). In fact, XMODEM doesn't appear to work too well on packet since the time delay between packets tends to time out the XMODEM counters. That part of phone BBSs has no application on packet.

The major difference between phone and packet BBSs is the sharing of the communications medium with other users. On the phone, you have the entire system to yourself, and the BBS can be as verbose as it wants and not bother anyone. On packet, it's different. There are any number of users on the BBS frequency, and a BBS that sprays unnecessary packets out is not very welcome. In particular, menus are a bad idea—they take too much time to transmit, and most users quickly learn the commands anyway. Also, phone BBSs frequently send extra line feeds in between messages to the user, which detract from the throughput on the frequency. In general, then, phone BBSs are not usually suitable for packet use.

What's Available?

There are a number of different BBSs available for packet use. If you look hard enough you can probably find something that will work on almost any computer. I've seen them for the Commodore 64, the TRS-80 Model 100, and the IBM PC. I'm not really familiar with these, so I won't discuss them in any more detail, except to say that if you decide to put something on the air, please make sure that it's appropriate for packet use.

There are two major packet BBS systems that operate in the EASTNET link. Since I'm familiar with them and not with the others, this article will focus on them.

The WØRLI MailBox system was written around 1984 by Hank Oredson WØRLI. It is written in 8080 and Z-80 assembler specifically for the Xerox 820 computer. Until recently, this computer was the optimal computer for the ham/computer hobbyist because he could pick up fairly good boards for between $50 and $75, add on two 8-inch disk drives, and put a power supply on to get a pretty good 64K CP/M computer. The Xerox 820 has two serial communications ports, which makes it ideal for packet applications. It's still a good machine, but the advent of the $700 PC clone is quickly eating into the market.

To take best advantage of the 820, Hank modified its CP/M specifically for the 820 and MailBox. It won't work on any other computer (so don't ask). Hank makes the source code available on disk, though; so if you're a good 8080/Z-80 programmer, you might want to take a crack at making it work on a different computer.

MailBox supports a number of special features for packet use, including: identification of the calling station at logon from the CONNECTED message; notification of waiting messages at logon; categories of messages, including bulletins and private mail; uploads and downloads of files; notification of another station waiting to use MailBox; "talk to the sysop" paging; capture buffers for sysop use when MailBox is down; automatic forwarding of messages to other MailBox systems; monitoring and logging of frequency activity; and many more. I'd guess that there are at least 100 of these systems operating all over the world.

The other system gaining widespread use is the WA7MBL clone of the WØRLI system. Written by Jeff Jacobsen for the IBM PC, this system looks like the WØRLI system to the user. Almost unbelievably, Jeff wrote the program in Turbo Pascal from Hank's 8080 source code without ever having used a WØRLI MailBox! It has a few features that WØRLI doesn't (and vice versa), but the main advantage of the WA7MBL system

TNC PARAMETERS

The parameters used on the TNC are critical to how well the BBS operates. Some parameters, like ABAUD and PARITY, are determined by the BBS hardware and software. Others, like TXDELAY, are a function of the radios. Of interest here are the parameters that control the way the TNC feeds the packets into the network: DWAIT, FRACK, RETRY, PACLEN, and MAXFRAME. These should be fine-tuned to the characteristics of the network. These are TNC-1 parameters. TNC-2 users adjust accordingly.

DWAIT controls the amount of time that the TNC will wait after seeing a clear frequency before it sends a waiting packet. It thus determines the priority of the stations on the frequency. A station with a DWAIT of 2 will always jump ahead of a station with DWAIT of 15. Since a BBS station sending a long file could literally shut down a frequency by using a low DWAIT, it must use a higher one to allow the shorter packets from the keyboard-to-keyboard people to go through. A BBS on a shared frequency should use a DWAIT of about 15 to be sure that the other users have a shot at the frequency. On a dedicated BBS frequency, though, a lower number should be used to increase throughput.

FRACK is the amount of time that the TNC will wait after sending a packet and not receiving an acknowledgment before sending the same packet again. FRACK should be set considering the load on the network. When the network is heavily loaded, an acknowledgment packet may wait at a station for several seconds until the frequency is free. If the sending station has FRACK set too low, it will re-send the same packet even though the receiving station heard it the first time. This creates needless clutter and slows down the transfer of the data. For normal use a FRACK of 4 should be appropriate, while on moderately heavy links a FRACK of 8 or more is better.

RETRY governs the number of times the BBS will repeat a packet before giving up. This is important for a BBS sending long packets, especially those in the opening greeting message. Often a station will connect with a BBS, but won't hear the BBS well enough to hear its packets. If RETRY is set high, the BBS will pump out its three- or four-line greeting message into the ether many more times than necessary. In general, if a station requires more than about five retries to use a BBS, the link isn't good enough and he shouldn't try it. We have our RETRY set to 6.

PACLEN determines the number of characters in the packet. Most TNCs are set to default to a PACLEN of 128 characters, but there are circumstances where a higher or lower setting may be appropriate. If conditions are bad, a shorter packet has a higher probability of making it through, and PACLEN should be reduced, possibly as low as 40. On the other hand, on a clear frequency with local links, PACLEN can be increased up to 256.

MAXFRAME sets the number of frames to be contained in a single transmission. A MAXFRAME of 4 means that four packets are sent at once. Like PACLEN, this parameter is also sensitive to frequency conditions. If conditions are good, using a higher MAXFRAME improves the speed of the data transfer, since more data is being sent in each transmission. On the other hand, if many packets are not getting through, a higher MAXFRAME means that more data is being wasted each time and that a better throughput could be achieved by reducing MAXFRAME.

Here are some recommended settings for these parameters:

- For a frequency shared with other users and BBS stations with moderate load: DWAIT 15, FRACK 6, RETRY 6, PACLEN 128, MAXFRAME 3.
- For a frequency heavily loaded with users, BBSs, and digipeaters: DWAIT 15, FRACK 10, RETRY 8, PACLEN 80, MAXFRAME 1.
- For a dedicated BBS frequency with no keyboard-to-keyboard users and strong links: DWAIT 2, FRACK 4, RETRY 4, PACLEN 256, MAXFRAME 6.

You should review the performance of your BBS and its impact on the frequency at frequent intervals, and adjust these parameters as appropriate.

is that it runs on the PC. This means that you have 360K floppy disks instead of the 241K disks for the 820. You can also put on a hard disk (I have a 10-megabyte hard disk on my system) and have almost unlimited storage. Jeff hasn't released the source code for the system (so don't ask) because it's still being tested. By the time this article appears, though, it may be available for general use.

There is also some basic documentation available for these systems, written by WB2MNF. The manual for the WØRLI system is fairly up-to-date and somewhat long (about 75 pages). The WA7MBL manual is a little shorter and less complete—hopefully it will grow over the summer when WB2MNF has more chance to work on it.

The disks and manuals are being handled by Wes Morris K7PYK at 7422 E. McKinley Street, Scottsdale AZ 85257; (602)-945-6079 or 946-8356. Wes will send you the disks and documentation for either the WA7MBL or WØRLI system for postage costs. Contact him for current prices.

Software Support

An important factor in setting up a BBS system is support from people who know what they are doing. One rule should be followed: *Don't call Jeff or Hank with questions!* With hundreds of installations springing up over the country, neither of these guys has the time to help every sysop get going. It's also best for the network to let Jeff and Hank spend their time writing code for the BBS systems, not talking on the phone.

So who do you call? The best place to start is your local sysop. He's obviously conquered the system or he wouldn't be on the air. Drop him a note on the BBS and tell him what you've decided and ask for help.

If there's no BBS in your area and nobody knows anything about them, you might want to check out the HAMNET SIG on CompuServe. There's an active packet group there and a special section for BBS sysops. A lot of active sysops hang out there and you can get answers quite quickly.

Equipment

As in any type of computer application, the availability of software determines the hardware to use. As I just described, there are two major types of packet BBSs in wide use—one running on an IBM PC or clone, the other on a Xerox 820. It doesn't take a whole lot of deductive ability to see that if you want to use either of these programs, you'll have to use one of these computers.

Xerox 820's were available in quantity about a year ago, but good ones are getting few and far between. A number of BBS operators who ran them and switched to PCs may have them assembled and for sale, so check around on the boards.

The PC clone is getting cheaper every day. Systems are offered at hamfests and computerfests for less than $800, complete with disk drive (or two), keyboard, monitor, and a very IBM-looking case. Check these things out and be sure that you know what you're getting. Although the WA7MBL BBS will run in 256K, many sysops use DoubleDos or some other multi-processing program to use the computer for something else while the BBS is running, and this will require much more memory.

You also might want to look into using a hard disk. Prices for these are dropping quickly, to the extent that a 10-megabyte hard drive will cost only about $125 more than a floppy drive. It's definitely the way to go if you can afford it.

A TNC is obviously required to set up a BBS system. With the plethora of TNCs springing up, some discretion should be exercised in deciding which one you should use.

The TNC you choose has to be supported by the BBS software. The WØRLI and WA7MBL systems support the TAPR command set, used by the TNC-1, the TNC-2, and their clones. If you use one of these TNCs, you're pretty safe. If you want to use something else, you should check with a sysop using the TNC you're considering to be sure that it works OK with the software.

The other consideration is how many TNCs you want to put up. Both BBS packages support two TNCs and rigs, allowing the BBS to cover two different frequencies, bands, baud rates, etc. This allows the WB2MNF BBS to access EASTNET on its primary frequency of 145.01, while also using 145.03 for local stations that only want to work the BBS. It also allows KC2TN to "gateway" messages from 2 meters to a group of BBS stations operating on 20 meters for long-haul traffic forwarding, and lets WB2RVX keep a port on 145.01 while maintaining capabilities for 9600-baud forwarding on 220 MHz when that becomes a reality.

The problem generally is that the primary frequency, which is where you want to do your forwarding, is generally too busy to support another BBS. You have to decide how you're going to maintain contact with the forwarding network without clobbering the stations on that frequency with "yet another BBS." Two TNCs and rigs may be the way around this.

Message Forwarding

One of the most useful features of a BBS is the ability to handle personal messages between packet users in the network. By "personal messages," I mean messages specifically addressed to an individual from another station. Stations logging into a BBS can be greeted by name and told of messages waiting for them. Messages are addressed to a specific callsign or to a designated name like ALL or NTS.

Packet radio jumped up a notch when WØRLI released the message-forwarding capability of his MailBox system. This allows the sysop to develop a forwarding file that lists the paths to other BBS stations and the calls of stations whose mail should be forwarded to that station. When a station leaves a message addressed to a station at a distant BBS, the local BBS will, at its appointed time, go off-line and connect with the distant BBS and send the message there.

With good coordination of sysops in a network, messages can be daisy-chained over long stretches in a remarkably short period of time, being relayed by a number of BBS stations along the way. This generally occurs overnight (except on HF), and it all happens without operator intervention. A message may show up from the south on a BBS, which will promptly relay it to the next station to the north—all without the sysop doing anything. The EASTNET network has reliable message forwarding from Canada down through Virginia and west to Pittsburgh on VHF.

Considerations

As a mail server, you should know about certain requirements on the BBS system. Some of these are:

Maintenance—If you want to handle a lot of mail, be prepared for more than the usual amount of maintenance. Mail files have to be compacted, old messages must be removed, and occasionally messages have to be recovered from system crashes.

Forwarding—You also have to coordinate mail forwarding with the other sysops in the network. It's important to know how to get mail to other BBSs, and it takes a coordinated effort to do it. If you expect to handle mail and can reach another BBS, get in contact with the sysop and work out the forwarding times and stations list with him.

Disk space—Mail files take a lot of space on a BBS. When I was running the WØRLI software on the Xerox, my whole B drive was mail files. I couldn't put anything else on there. This limited my ability to handle files—I just didn't have room to put up the *Gateway* newsletter every two weeks. Keep this in mind when you're planning your system. (*Gateway* is the bi-weekly packet-radio newsletter published by the ARRL. Excerpts suitable for transmission on the amateur bands can be found on many BBS systems. The full paper issue is available by subscription.)

File Transfers

The WØRLI and WA7MBL BBS systems will handle files as well as messages. Files may contain any type of information—text, programs, data, etc. Some of the files that I have on my system are issues of *Gateway*, tracking programs for the TRS-80 Model 100, minutes of the local packet organization, programs for the PC, news items downloaded from CompuServe, the text of relevant FCC issuances, a current set of Keplerian elements for ham-radio satellites, and descriptions of how to use the BBS. These can be loaded onto the BBS by the sysop, as well as by users.

There are a number of sources for these files. Some are created by the sysop or from messages sent by others. Some, like the ARRL bulletins, come from a different amateur-radio medium. Others may come from land-line BBSs, from commercial timesharing services like CompuServe's HAMNET special interest group, from DRNET or USENET, or from BBS users who have access to these services. With good coordination among sysops, many can be forwarded from BBS to BBS.

The sysop has a responsibility to try to get useful information to his users. Many sysops spend their own money on commercial services to get information that isn't available elsewhere. Whether you do this or not is up to you, but if you let the files on your BBS stagnate, you're not adding as much as you could to the packet network.

Don't overlook the opportunity for your users to contribute files to the packet network. Many packet users have access to these types of services also. If you can enlist the aid of a few individuals to help you keep your files up-to-date, it will save you a lot of time and make your BBS more useful to the local packet community.

Programs

One good use of packet radio that hasn't been explored a lot is the transfer of computer programs. If your users include a number of computer hobbyists, this might be an interesting area for you. Programs can be either ASCII text files (Basic programs or other source-code files) or, with a little adaptation on both ends, binary files.

First, though, you have to consider a few things. What kind of computers are you going to serve? What do most of your potential users have? Most will probably have a different type of computer than you do, which means that you may not be able to run the programs that are going to be transferred through your BBS. That shouldn't be too much of a problem, but it might be a little disconcerting to you.

Commodore 64 computers use a strange version of ASCII called PETASCII. This means that you can't just read an ASCII Basic into a C-64—before you send the file, you have to convert it from PETASCII to ASCII, then convert it on the other end back into PETASCII.

IBM PCs and clones use Basic programs as straight ASCII files, so they can be transferred with little additional work. If you want to transfer COM or EXE files, though, you have to convert them to hexadecimal format before you transfer them to the BBS. This is because the BBS programs described in this article operate in CONVERSE mode, which doesn't pass all binary characters, rather than in TRANSPARENT mode, which does.

There are several programs that will perform this conversion—the one we use at WB2MNF is called HC.COM and came from CompuServe. There's also a Basic program called MAKEHC.BAS, which will create the file HC.COM. The advantage to MAKEHC.BAS is that it's ASCII and can be downloaded directly by any user, who then runs it to create HC.COM. Once he has HC.COM, he can convert back to COM or EXE the files that you had to convert to hexadecimal on the BBS. HC.COM goes both ways—from COM or EXE to hexadecimal and back.

Many computers use Basic as a sort of operating system. These computers may or may not accept Basic programs in ASCII format. Frequently Basic is "tokenized"—each Basic command or keyword is held as a specific symbol rather than the text of that word. Thus, instead of holding the PRINT command as the letters P-R-I-N-T, Basic would use a single 8-bit symbol to represent the PRINT command. The TRS-80 Model 100 uses this approach, as do a number of other computers.

Many of these computers provide for converting tokenized Basic to ASCII text, and this would be the easiest way to transfer these files through the BBS systems. Failing this, they would have to be converted to hexadecimal files as described above.

How Big Can Programs Be?

Another consideration relating to transfer of program files is the capacity of the network to pass large files. If your BBS operates on a dedicated BBS frequency, you can probably pass quite large files. On the other hand, if you share a frequency with other BBSs and users, your capacity for large file transfers is quite limited. On the 145.01 general frequency used in our area, the maximum file size that can generally be passed without losing the connection is about 15,000 bytes. On 145.03, which is a dedicated BBS frequency, we have transferred files in excess of 60,000 bytes with no problems. Since making a hexadecimal file out of a COM file will double its size, and since many interesting COM files are larger than 20,000 bytes, you may be limited in your ability to transfer anything useful by the capacity of the network in your area.

One side note: The problem with passing binary files occurs only with BBSs that can't operate in TRANSPARENT mode. If you're transferring files between two TNCs and can operate that way, there's nothing stopping you from transferring binary data.

Getting Set Up

Once you've worked out all the nontechnical aspects of getting the BBS operational (you know what frequency you're going on, how you're going to forward mail, where you're going to get file data, etc.), it's time to start hooking things together. The hookup between the radios and the TNCs isn't too complicated, and I'll assume that you've been able to do that already. The TNC connects to the serial port of the computer with an RS-232 cable similar to the one used to hook up a modem. You have to be sure that you have all of the pins of the cable connected from one connector to the other since various versions of both systems use the handshaking lines of the cables to tell the computer and the TNC when the other is ready.

You also have to configure some files for the BBS. Both systems have configuration files, which allow you to customize the boards to a large degree. Generally you can alter anything the BBS says to a user—the greeting message, prompts, error messages, etc. Edit the configuration files, read the explanation on the lines, and change the information appropriately.

The forwarding file also has to be set up. This file is called FWD.TNC on both systems and determines which messages get forwarded to which BBS stations. It also determines which hours you will forward and which you won't. This allows you to avoid forwarding mail during prime times when the frequencies are in heavy use.

Forwarding files specify where messages addressed to certain stations should go. The format of a forwarding file is:

```
FAsseeC bbs VIA digi1, digi2
station1
station2
etc.
*** EOF
```

where *ss* is the starting hour for forwarding, *ee* is the ending hour for forwarding, *bbs* is the call of the BBS to which you wish to forward mail, *digi1* and *digi2* (and any other digipeaters) are the digipeaters through which you have to digipeat to get to the BBS, and *station1*, *station2*, *etc.* are the stations whose mail should be forwarded to the BBS.

Stations that originate messages specify that mail should be forwarded to a distant BBS by following the call of the addressee with an @ sign and the call of the distant BBS. Thus, to send mail to WB2AFM, who receives his mail at the W1AW BBS, the command is: S WB2AFM @ W1AW. This presumes that the BBS at which the message was originated has W1AW in its forwarding file.

Sometimes your BBS can't forward to the destination BBS directly and must send messages to an intermediate BBS, which will then take care of forwarding it on down the line. This happens in EASTNET quite frequently. If a message is originated on the W3IWI BBS in Maryland and is addressed to a station using the W1AW BBS, W3IWI doesn't attempt to forward it directly to W1AW. Instead it will send it to WB2RVX in southern New Jersey, which will forward it to WA2SNA-2 in northern New Jersey, which may forward it to AI2Q on Long Island, New York, which may deliver it at W1AW. This all happens automatically without the manual intervention of the sysop, and generally occurs overnight. As you can imagine, though, it requires a lot of coordination among the sysops to be sure that the messages get going in the right direction.

You'll have to get together with the sysops in your area to decide on forwarding times. Each station in a network is assigned a time to forward messages to the other stations. Times must be coordinated so that two stations don't try to forward to each other at the same time.

A Real Live BBS System

It might be useful to look at an operating BBS station to see how things might be organized. The BBS at WB2MNF has been operating since November of 1984, first on a Xerox 820 running the W0RLI program and recently using a PC/XT clone dedicated to the BBS with the WA7MBL code. We handled over 7,000 messages on the 820 and are up to about message 1,500 on the PC.

The PC has a 10-megabyte hard disk, which provides for plenty of storage space. About 5 megabytes is filled with packet files,

with the rest used for other things. The disk is divided into "directories," which separate the files into logical groups. I have directories for AMSAT, ARES, GATEWAY, MODEL100, IBMPC, and several other areas of interest.

I use the DoubleDos program available from SoftLogic, which lets me run the BBS program on one "side" and still have access to the computer on the other. I can switch between them at will. Others who "share" their computers with the BBS may use DoubleDos, DesQview (from Quarterdeck Software), or some other multi-tasking program to use the computer for something else while the BBS is running.

The WA7MBL program lets you operate the BBS with two different TNCs and radios on two different frequencies. The primary frequency in our area is 145.01; it's crowded almost constantly, so I run one port on 145.01 and the other on 145.03. When one is in use the other is unavailable, but it does provide access for distant users on .01 while letting more local users enjoy less QRM on .03. I have two TAPR TNC-1s connected to an IC-27A and an Isopole on .03, and an IC-251 and OSCAR twist on .01. Although not optimal, this lets me cover most of the local service area.

Personal Message System

One message-handling system that has received surprisingly little attention is the Personal Message System (PMS). A PMS is a BBS system that handles data only for its sysop. At first glance this may seem a bit selfish, but under careful consideration it makes a lot of sense.

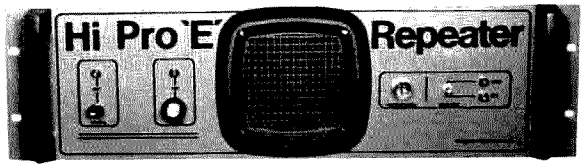
A PMS allows the sysop to compose a message to another station without having to be connected to a BBS. The message stays on the PMS and can be read by the addressee if he happens to log in. If not, the PMS forwards the message to the addressee (if he also has a PMS) or to the addressee's BBS. This can happen overnight or during other periods of light use of the frequency. It also makes things a lot easier for the user—at night you type in all of your mail, and by the next morning it's been delivered to the destinations and you have new mail that was forwarded to you. It's the difference between having mail delivered to your front door or having to go to the post office.

Any of the BBS software mentioned earlier can be used as a PMS. There are also default parameters in the forwarding files that let you say, in essence, "Send any mail not addressed to me to the W1ABC BBS." This lets you forward all outgoing mail to your local BBS, which will then distribute it into the network.

If you don't happen to have a PC or Xerox 820 to use for a PMS, but would like to try a receive-only system, W3IWI demonstrated that the TNC-2 and clones can be set up to operate that way. The WØRLI and WA7MBL BBS systems look for the following sequence of responses when connected to a BBS to which they are forwarding: the > character at the end of the prompt line, two lines ending with a <cr> character, and another > character at the end of the next prompt line.

This sequence can be programmed into the CTEXT of the TNC-2 and should be repeated to allow several messages to be forwarded during one connect. The computer connected to the TNC should have a "capture buffer" or "save to disk" enabled to record the forwarded messages. Finally, the MONITOR function on the TNC should be turned off to keep from filling the buffer with every packet that comes through.

Packet users wanting to use this system should notify their local sysop that they want to accept forwarding. The sysop will then add their station to the forwarding files of the BBS, and any messages arriving at the BBS should be forwarded to them at the next forwarding time.



Conclusions

If being a sysop doesn't sound like the picnic that you thought it might, then you haven't missed the point of this article. Packet-radio bulletin-board systems are an important addition to local packet activity and will form an important part of the ever-expanding packet network. There's a lot to making them work effectively, though, and sysops should be aware of the considerations surrounding their operation. Even if you don't want to be a sysop, knowing what a sysop has to go through can help make you a better user. ■

Hi Pro Repeaters
MELCO

Hi Pro 'E'

EXPANDABLE REPEATER SYSTEM

• A NEW CONCEPT IN REPEATER DESIGN, THE Hi Pro "E" IS AN EXPANDABLE REPEATER WITH THE FOLLOWING FEATURES: A BASIC REPEATER WHICH WOULD INCLUDE A COMPLETE RECEIVER, TRANSMITTER, COR, FRONT PANEL CONTROLS AND INDICATORS, LOCAL SPEAKER AND MIC JACK AND CAPABLE OF FUTURE EXPANSION. ALL HOUSED IN AN EXTREMELY RUGGED, ENCLOSED, 19-INCH RACK MOUNTABLE CABINET.

• THIS SYSTEM CAN BE EXPANDED AT TIME OF PURCHASE OR CAN BE AN AFTER-PURCHASE ADD ON. THE ADD ONS ARE—HIGHER POWER, 110/220 VAC POWER SUPPLY, IDENTIFIER, AUTO PATCH, OR COMPUTER CONTROLLERS. IN ADDITION TO THESE ADD ONS AN ADDITIONAL RECEIVER AND TRANSMITTER CAN BE MOUNTED INTERNALLY FOR USE AS CONTROL LINKS, REMOTE BASE OR DUAL BAND OPERATION, ETC.

• AN EXTENSION PANEL IS AVAILABLE FOR LOCAL MONITORING OF THE REPEATER AND CONTAINS ALL NECESSARY METERING, STATUS LIGHTS AND INDICATORS. ALL ADD ONS ARE AVAILABLE FROM THE COMPANY AND ARE COMPLETE INCLUDING INSTRUCTIONS. THE Hi Pro "E" IS AVAILABLE IN NOVEMBER.

Birds 'N' Bauds

Satellites are going digital in a big way—five international experts combine to define our place in space.

The packet-radio revolution has slipped the surly bonds of Earth and is headed for orbit. Two amateur spacecraft slated for launch in 1986 have dedicated general-access digital links. A satellite already in orbit carries a digital store-and-forward communications experiment. Digital communications figures into the plans of several satellites currently on the drawing boards. This article will discuss digital activity on the high frontier, and will help you prepare to use the new digital fleet as it becomes available.

The first section of this article (written by Harold Price NK6K) supplies a bit of background and discusses the digital facilities of UoSAT-OSCAR-9 and -11. The second section (written by Tak Okamoto JA2PKI) describes the mailbox on the JAS-1 spacecraft, scheduled for launch on August 1st of this year. The third section (written by Hanspeter Kuhlen DK1YQ, RUDAK Experiment Project Leader; Peter Guelzow DB2OS, Deputy RUDAK Project Leader; and Donald Moe DJØHC/KE6MN, Member of RUDAK Group) describes the RUDAK packet transponder, which is slated to be a part of Phase-3C, scheduled for launch in October.

This article is not intended to be a general satellite tutorial, rather it is a survey of the interesting things going on digitally, to entice you into finding out more. See reference one for an excellent text on amateur satellites for both the beginning and advanced amateur.

INTRODUCTION

Microprocessors and digital communications have played a part in all of the recent amateur spacecraft. They have usually been dedicated to telemetry and command functions, however, as well as on-board control. The AMSAT-OSCAR 10 (AO-10) spacecraft is completely dependent on its on-board computer for control. The UoSAT-OSCAR-9 (Uo-9) and Uo-11 spacecraft can be controlled directly from the ground, but each carries several microprocessors that carry out autonomous spacecraft control under normal conditions. Although these and previous spacecraft use digital data to send telemetry and receive commands, the spacecraft launched in 1986 will be the first to carry digital equipment as part of the two-way communications payload accessible to the amateur community at large.

Spacecraft can be used to enhance digital communications in several ways. The first is as a one-way digital beacon. Uo-9 and Uo-11 transmit informational bulletins as well as spacecraft telemetry. The data format is easy to decode, and receive-only ground stations are easy to build.

One two-way application is simply to use a spacecraft as an analog repeater. AO-10 serves in this capacity now. It receives rf on one band and simultaneously retransmits it on another band, with no processing of the signal. Any mode can be repeated by the satellite, including SSB, RTTY, SSTV, and packet. Power-inefficient modes such as FM, while they are repeated like any other signal, are not permitted on AO-10. Packet can be sent through AO-10; in that respect, AO-10 acts like any normal voice repeater—any re-

peater on a mountain 33,000 km high, that is.

A second two-way use of a spacecraft is as a digipeater. There are several advantages to this style over the AO-10 method where packet is concerned. First, packets are checked for accuracy in orbit before being repeated. This saves time otherwise wasted by downlinking a damaged packet. Second, each packet starts "fresh" from the orbiting digipeater. Since it is regenerated, the repeated packet does not already suffer from the effects of getting to the spacecraft (free-space loss, transponder loss, etc.); it need only make it from space to the ground.

The best space-based digipeater is one that is visible for long periods of time and covers a lot of ground. The RUDAK module on the Phase-3C spacecraft will serve in this function. Phase-3C will be visible for as long as nine hours at a time, and can digipeat packets to more than 1/3 of the Earth's surface for a large portion of that time.

A third two-way use of a spacecraft is as a mailbox, which stores information for later retrieval. A store-and-forward satellite, as this class is called, can deliver messages on a worldwide basis using only a single satellite. A satellite in the proper orbit could continually gather and deliver messages as it moves over the globe. A low-orbit satellite is well-suited for this task since it makes many passes overhead each day. Such a satellite is not well-suited for use as a digipeater, though, because only small (compared to Phase-3 orbits) areas can see the satellite at one time. The JAS-1 spacecraft will serve in a mailbox role; Uo-11 is already performing this function on a limited basis.

UoSAT Spacecraft

We'll start our discussion of specific spacecraft with two that are in orbit now: Uo-9 and Uo-11.

Uo-9

The UoSAT-OSCAR-9 spacecraft was the first to offer high-speed digital telemetry from orbit. Previous spacecraft had sent telemetry by using Morse code, and some could even receive messages from ground command stations for playback on the Morse beacon. Uo-9 runs standard ASCII data at 1200 baud, and can thus send many thousands of characters in a pass. Uo-9 carries a regular bulletin service, with bulletin sizes in the 5-to-10K range. The bulletins carry information about amateur satellites, including operating schedules and orbit predictions, and are transmitted in plain text.

Uo-9 transmits using FM at 145.825 MHz. It can be heard on a hand-held from out in your front yard (see Photo A). To recover data, however, you will probably need a beam antenna. For best results, you will also need to know when to listen. A variety of orbit-prediction programs are available for nearly all makes of computers, including TS-1000, VIC-20, C-64, TRS-80, Apple, and IBM PC. Contact AMSAT for information (PO Box 27, Washington DC 20044).

Any Bell 202 standard 1200-baud modem can be used to read the Uo-9 data stream. The Bell 202 standard uses 1200-Hz and 2200-Hz tones. Surplus modems are available at larger computer swap meets in the $25-to-$90 range. Most 1200-baud modems used with personal computers are *not* suitable, however. They use the Bell 212 standard, which is a horse of a different color. The 1986 ARRL *Handbook* describes a simple modem that can be built from scratch. The bulletins are transmitted in clear text, and are sent at regular intervals. Telemetry and other data are alternated with the bulletins. For stations currently beyond the reach of the VHF and HF packet network, the Uo-9 bulletins present information weeks or months before the paper periodicals.

Uo-9 was launched in October, 1981, and carries a number of experiments. Uo-9 is similar in appearance to its sister craft Uo-11, pictured in Photo B.

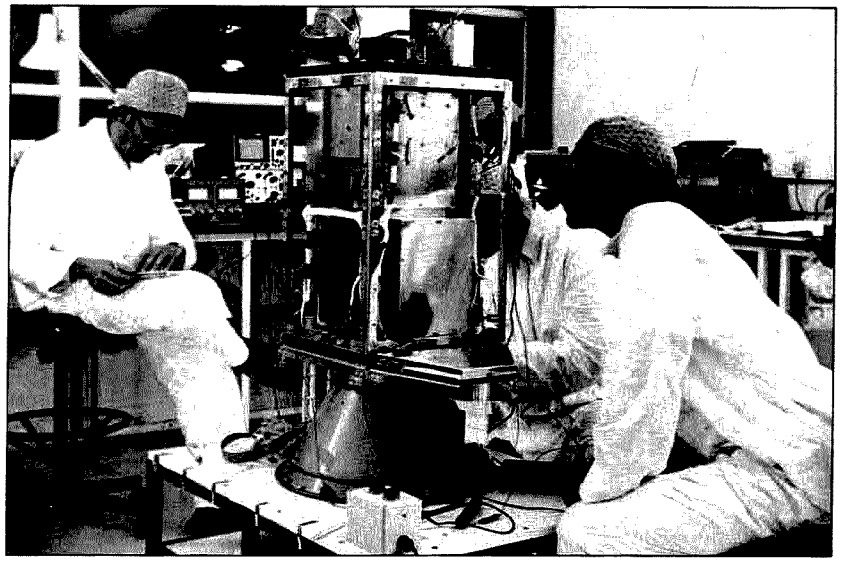

Photo C. Uo-11 under construction at the University of Surrey.

Uo-11

Uo-9 offers a one-way bulletin service. The main spacecraft computer's memory is used to contain the message text, and the main computer is used to transmit the bulletins. Because of this, only the primary control station is able to upload bulletins. Uo-11, on the other hand, has a separate processor with its own data storage. This permits experimentation with an orbiting store-and-forward mailbox with reduced hazard to the spacecraft itself. A store-and-forward capacity means that messages are uploaded to the spacecraft and held there until a second ground station commands their retrieval.

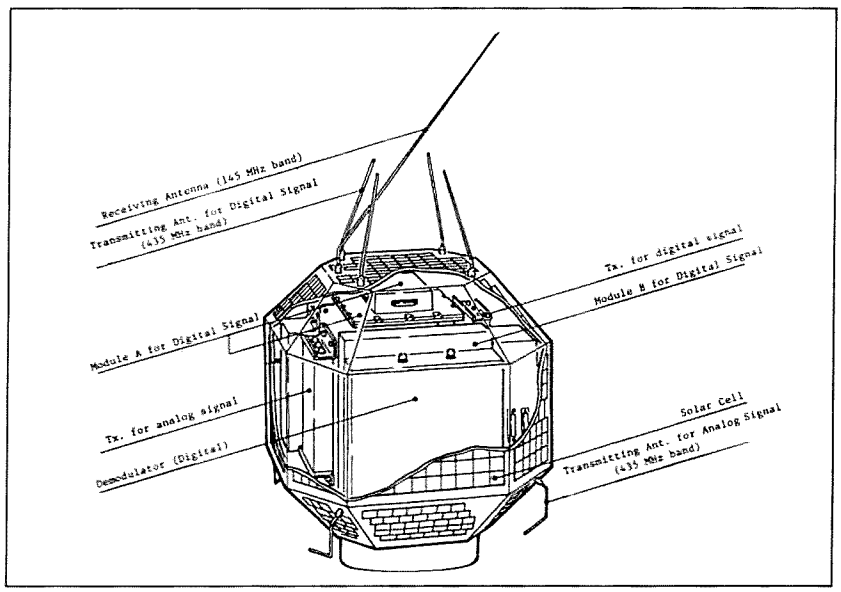

Fig. 2. JAS-1, showing internal packaging and antennas.

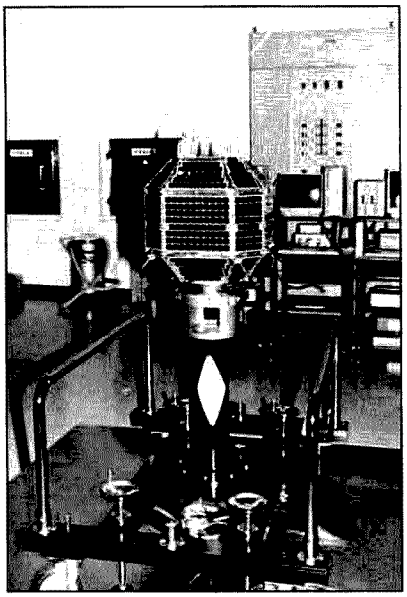

Photo D. JAS-1.

The Digital Communications Experiment (DCE) provides this service. The DCE is a self-contained microcomputer carried as one of several experiment modules on board Uo-11. It was designed and built by amateurs and others in Canada and the United States. The DCE contains 126K of memory for program and message storage. In the current software configuration, 96K is available for messages. The DCE contains an NSC-800 microprocessor, which behaves like a CMOS Z-80.

Although the DCE is a separate facility, it still shares the main downlink beacons and command uplink frequencies. This limits the number of stations that can transmit messages directly to Uo-11. Therefore, the Uo-11 DCE is best suited for access via gateway stations. A Uo-11 gateway station collects traffic from local or regional terrestrial packet systems and forwards it to the satellite. It also retrieves messages destined for its area and distributes them. In this manner, a large number of amateurs can take advantage of the DCE even though only a few can transmit to it directly.

The DCE is also being used for large file transfers. These files usually contain technical papers, bulletins, and newsletters. In the past few months, nearly one million characters have been passed between ground station NK6K in Los Angeles and ground station G0/K8KA at the University of Surrey. These two persons collaborated on a paper, transferring a 20K file six times across the Atlantic in a few days.[2] There were three active gateway stations in May of 1986; several more are planned for the near future. Many messages have been relayed to and from the ground-based packet network, and the techniques learned and the software developed will be directly applicable to JAS-1 gateways. As discussed later, JAS-I will be available to anyone, and a large number of direct and gateway users are anticipated.

Uo-11 also carries bulletins similar to those on Uo-9. It transmits ASCII data with the same modem tones as Uo-9, but the sense of the mark and space tones is reversed—Uo-11 data is "upside down"; in the U.K., the BBC microcomputer considers this to be "right-side up." To decode Uo-11 data with whatever you have to decode Uo-9 data will require inverting the data stream. The possibly least-elegant solution to this problem is presented in Fig. 1. Its advantage is that it will work in-line between the modem serial output and the computer's serial input. Its disadvantage is that it works only with computers that can deal with RS-232 data swinging between 0 and +12 volts. My IBM PC has no problem with these levels, and neither does a vintage S-100 CP/M system.

Uo-11 was launched in March, 1984, from California. It transmits on the same frequency as does Uo-9: 145.825 MHz.

JAPAN AMATEUR SATELLITE-1 (JAS-1)

(A note to our Japanese readers—Tak Okamoto JA2PKI/N6MBM, a temporary resident of southern California, returned to Japan shortly after this collaborative article was begun. I've expanded on one or two items. If something below is not said in the Japanese way, my apologies. It's not Tak's fault; he did his best not to get tainted by California while he was here. I'm sure any behavioral aberrations are temporary and will soon wear off now that he has returned home.—NK6K)

JAS-1 is an amateur radio satellite, promoted by JARL (the Japanese national radio society) as a joint venture with NASDA (the national space agency). NEC (a large electronics company) constructed the "system" units (space frame, power supply, etc.), while JAMSAT (the national amateur satellite group), with its selected volunteer JAS-1 project team, designed and built the "mission" units (transponders, telemetry/command, and housekeeping microcomputer) and ground support systems.

JAS-1 has been completed and has passed all the necessary tests. It is in a clean room waiting for the launch, currently scheduled for August, 1986.

JAS-1 Mission Objectives

JAS-1, like Uo-11 and Phase-3C, is a shared mission; packet radio is not its only task. Since this is the first craft in its series, we'll take a broad look at the spacecraft and its mission before delving into the packet specifics. The objectives of JAS-1 follow:

- To provide reliable worldwide amateur radio communications.
- To enable radio amateurs to study tracking and command techniques.
- To offer an in-space "proving ground" for radio-amateur-developed and -built transponders and subsystems.
- To provide NASDA an opportunity to carry out a "multi-payload" launch using their

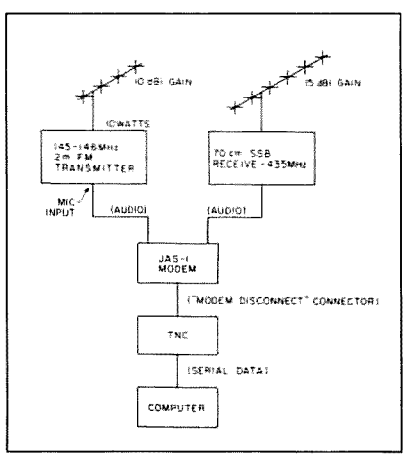

Fig. 3. JAS-1 digital ground station.

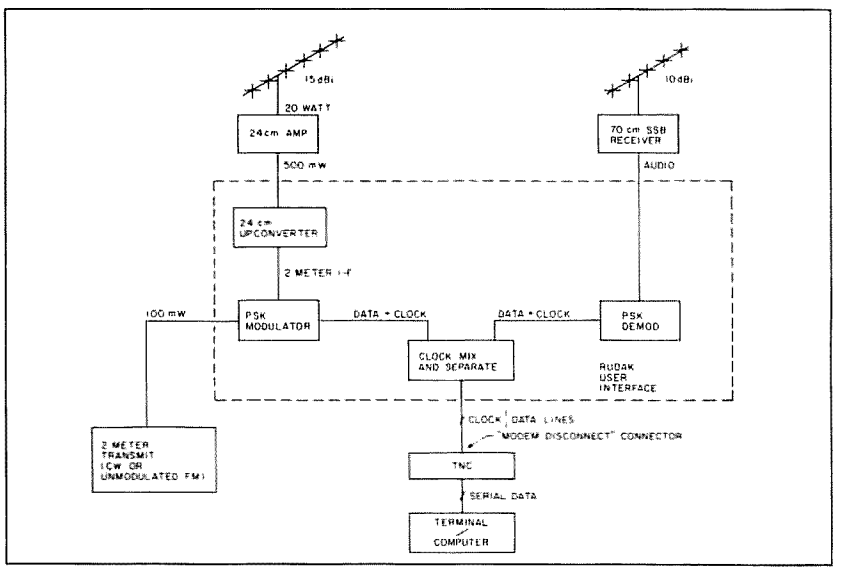

Fig. 4. RUDAK ground station.

new "H-1" launcher. (NASDA has never engaged in a multi-payload launch; thus, the JAS-1 project will offer NASDA an excellent opportunity by providing them with an active payload having its own telemetry beacon and transponder for ranging.)

The spacecraft takes the form of a 26-facet polyhedron, which measures 400 mm x 400 mm x 470 mm and weighs 50 kilograms (see Photo D and Fig. 2). JAS-1 will be launched into a circular orbit by a two-stage rocket. The orbit will be low, about 1500 km, but higher than the Uo-11 orbit of 800 km. JAS-1 will have an inclination of 50 degrees, which will result in a different cycle of passes from most previous low-orbit amateur satellites. Since most tracking of amateur satellites is done with computers, this will pose no problem. JAS-1 will take 120 minutes to circle the Earth, and will be visible for about 20 minutes per pass. There will be approximately eight passes per day.

JAS-1 carries two separate mode-J (2 meter up, 70 cm down) transponders. One is a linear transponder, and the other is a digital "store-and-forward" transponder, mainly for non-real-time communication between stations located in different time zones.

The reasons for selecting mode J for this first Japanese amateur radio communications satellite are:

a) It is becoming increasingly difficult to use 145 MHz for a satellite downlink because of man-made electrical noise and other interference. This is especially true in Japan where the 2-meter band is crowded with simplex activity.

b) The planners of JAS-1 wanted to provide a successor to AMSAT OSCAR-8's mode J, which was originally developed by JAMSAT's engineering team back in 1976.

c) 435 MHz is much quieter than 145 MHz as a downlink band; it is comparatively free from man-made noise and sky-temperature effects.

Communications Parameters

The standard analog linear transponder is called mode JA. The passband will be 100 kHz wide. The transponder will have an output of 1 Watt PEP. Ground stations will need an uplink power of 100 Watts eirp. The sidebands will be reversed—i.e., the uplink is LSB, the downlink is USB. There will be a 100-mW CW beacon switchable to PSK when needed. See Table 1 for details.

The digital transponder is called mode JD. There will be four 145-MHz-band input channels using Manchester-coded FM for the uplink. Ground stations will need a transmit power of 100 Watts eirp. There will be one downlink channel in the 435-MHz band using PSK; the output will be 1 Watt rms. See Table 2 for details.

The data format is HDLC. The protocol is AX.25 level 2 version 2. The data-transfer rate is 1200 bps for both uplink and downlink.

The reasons for not using Bell 202 type FSK modulation are:

a) To reduce the parts count on board JAS-1. Using Manchester-coded FM for uplink reduces JAS-1's on-board decoder chip count by 16.

b) To improve the downlink margins. Due to JAS-1's tight power budget, only 1 Watt is generated by the downlink transmitter. A more efficient modulation scheme like PSK is required.

JAS-1 will be a store-and-forward system, but not a real-time digipeater. Digipeating is not an effective use of a low-orbit satellite such as JAS-1, which has a limited communication footprint and visibility time.

JAS-1 has four uplink channels and one downlink channel. This is because of the difference in channel efficiency between uplink and downlink. An uplink channel is shared by several ground users. Since the ground users can't hear each other and are listening to the downlink channel anyway, the uplinks are subject to packet collisions. This scheme is called "Pure ALOHA," and is known to have a theoretical maximum channel throughput of 18.4%. The JAS-1 downlink is much more efficient, since only JAS-1 transmits there. To balance capacity, as well as add redundancy, four uplink channels are used.

The combined uplink efficiency is then 4 x 18.4%, or 73.6%. The remaining downlink time is used for general messages and telemetry data.

JAS-1 will accept a connect from only one station at a time with the software scheduled for initial use. Multiple connections will be supported in subsequent software updates. General packet operation is scheduled to begin in November of 1986.

Spacecraft Digital Hardware

The microprocessor is a MIL-STD-883B screened NSC-800 running with a 1.6-MHz clock. This is the only processor on board. It

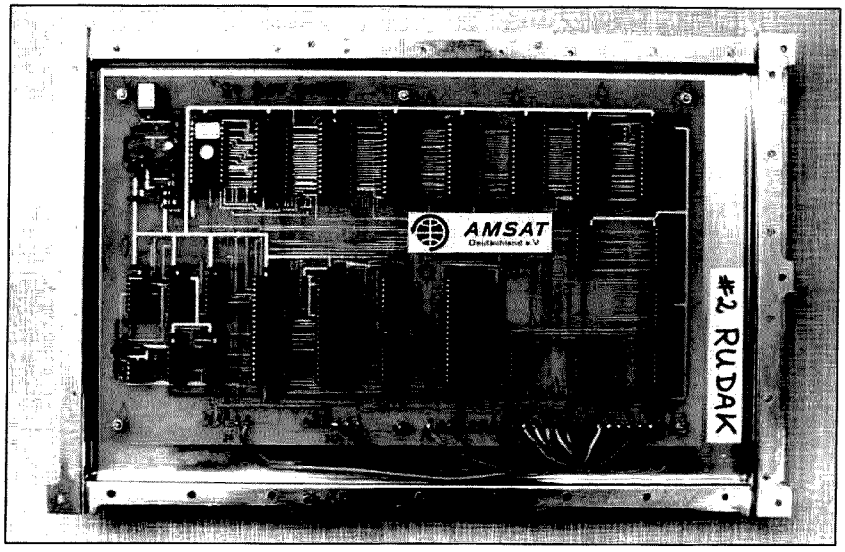

Photo E. RUDAK engineering prototype #2.

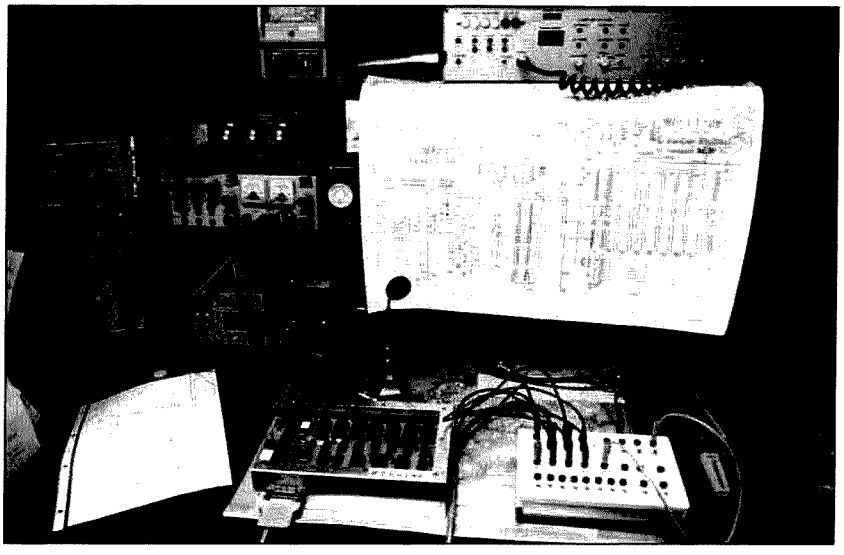

Photo F. RUDAK wire-wrap prototype.

controls the digital transponder and also acts as an IHU (Integrated Housekeeping Unit).

The on-board memory has a 1.5-megabyte physical storage capacity and uses 48 chips of NMOS 256K DRAMs. A hardware-based error-detection/correction circuit is incorporated to protect the entire 1.5 megabytes and provide a 1-megabyte error-free memory area. The system program occupies some 32K; the rest is used for message storage.

The memory unit is physically divided into four identical 256K memory cards, any one of which can be assigned as the system area. Up to three cards can be turned off. This design provides system redundancy and allows command stations to control power consumption without a total loss of service.

JAS-1 has five hardware HDLC controllers. Four of them are for the uplink channels and one is for the downlink channel. In total, these controllers consist of some 140 CMOS MSIs, yet their power consumption is less than that of a single NMOS LSI HDLC controller like WD-1933.

JAS-1 does not have any ROM but has a simple hardware boot-strap circuit instead. This design is to increase system flexibility and reliability.

Uplink passband:	145.90 MHz–146.00 MHz (LSB)
Downlink passband:	435.80 MHz–435.90 MHz (USB)
Beacon frequency:	435.795 MHz
Translate frequency:	581.80 MHz
Transponder output:	1 Watt PEP
Required uplink power:	100 Watts eirp

Table 1. Mode JA parameters.

Photo H. DL2MDL, DG2CV, DK1YQ, and DB2OS discuss final changes necessary in the processor circuit.

Ground Stations

The ground-station setup that was used for AMSAT OSCAR-8 mode J can be used for JAS-1 mode JA. A station with a 10-Watt 2m SSB transmitter, a 10-dBi beam for uplink, and a 70-cm receiver with low noise figure with a 15-dBi beam for downlink should be adequate for the job.

To use the JD transponder, FM mode is required for the 2m transmitter. Antennas and power levels are the same as for the mode-JA transponder. Since JAS-1 uses the standard AX.25 protocol and 1200-bps data rate, ground stations will be able to use a TAPR-style TNC, a 2m FM transmitter, and a 70-cm receiver without modification. A mode-JD station is shown in Fig. 3.

The JAS-1 modem, a special interface board, will be made available containing the Manchester modulator and an audio PSK demodulator to allow connection to the "modem disconnect" connector of TAPR TNC-1- and TNC-2-style TNCs. TNCs that don't have a provision for an external modem, such as the Kantronics Packet Communicator, will not be suitable for use with JAS-1. The modem connects to the audio input and PTT of the 2m FM transmitter and to the audio output and frequency control (option) of a 70-cm SSB receiver. JARL is working with TAPR to produce JAS-1 modem kits.

Although JAS-1 will be available for direct access by any amateur, non-satellite-equipped users can still take advantage of its message transfer facilities by the use of JAS-1 gateways. Gateway stations will be connected to local and regional packet networks as well as to JAS-1. JAS-1 can then be used as a relay between gateway stations and, therefore, between amateurs using the gateways to pass traffic.

RUDAK

In October of 1986, another Phase-3 satellite will be carried by an ARIANE IV launcher from the European space center (CSG) in Kourou into its elliptical orbit. A new type of amateur radio transponder will then come into service for the first time—RUDAK.

What Is RUDAK?

Basically, RUDAK is a freely programmable general-purpose computer with 56K RAM. A ROM operating system (ROS) provides general initialization after power-on.

Similar to a TNC board for packet radio, it will be programmed to provide a "TNC in the sky." Two links—one uplink from the ground to RUDAK and one downlink from RUDAK to the ground—provide the communications channel through an intelligent hardware interface. RUDAK is a German acronym for Regenerativer Umsetzer fuer digitale Amateurfunk-Kommunikation (regenerating translator for digital amateur radio communications).

What can RUDAK do for you? First, it acts like any other packet-radio station, by digipeating packets in real time between two stations that are both within view of the satellite.

Second, it will periodically insert bulletin packets into the downlink data flow, such as the momentary values for mean anomaly, orbit number, time, doppler shift (in reference to the equator), agc of the linear transponder, etc. The information is kept current by a constant data exchange between the satellite's main computer and the RUDAK processor.

Third, it will support a "robot" mode, which permits brief connects to the satellite for retrieving specific information of limited interest, such as orbital parameters, attitude information, transponder operating schedule, etc. To prevent a complete clogging of the system during periods of high traffic volume through RUDAK, a "list" type operation will be implemented. This operation will automatically limit the digipeated packets to those from stations that have signed onto the list by connecting to one of RUDAK's robot ports. This list will be constantly updated based on disconnects, timeouts, and other factors. Additionally, AMSAT or IARU bulletins can be periodically transmitted.

What does the RUDAK experiment consist of and what's necessary to participate? Let's start with the originating point of a packet that RUDAK will relay, the ground station. First, the packet is generated in the usual way in a TNC, but the internal FSK modem is disconnected. The transmit signal (data and clock) plus PTT are routed to a 2400-baud BPSK modulator, which forms a part of the transmitter on 1269.675 MHz $\pm$7.5 kHz to compensate for doppler and other frequency errors. Uplink power needs to be on the order of 20 Watts into a right-hand circularly polarized 15-dBi gain antenna, or approximately 650 Watts eirp.

The demodulator in the RUDAK receiver scans within a 15-kHz-wide capture window at a rate of 10 times per second. The appropriate TNC parameters will be provided in the automatic beacon packets. The packet is processed and routed to the downlink transmitter on 435.675 MHz using PSK modulation at 400 baud (or alternatively 1200 baud, depending on link conditions). This beacon will be in operation continually, except when mode B is switched on for brief intervals. Mode B is the 70 cm up/2 meter down mode that OSCAR 10 uses most of the time.

The RUDAK signal can be received using a standard SSB receiver, a 10-dBi right-hand circularly polarized antenna, and a preamplifier with a noise figure of 5 dB, which will achieve an estimated bit error rate of better than 10^{-5}. The audio signal is then fed into a PSK demodulator, where the data and clock signals are recovered. These two signals are sent to the corresponding TNC inputs.

The difference in uplink and downlink baud rates (2400/400) is due to the nature of the uncoordinated time-division multiple access to the system by the ground stations (ALOHA-TDMA). The collisions between stations on the uplink frequency result in only an average of 18% of the uplinked data getting through. This is because these stations can't hear each other. To balance out the downlink's 100% capability (only RUDAK is on the downlink), the uplink is run much faster. JAS-1 addresses the same problem in a different way—by offering multiple uplinks.

Uplink channel 1:	145.850 MHz
Uplink channel 2:	145.870 MHz
Uplink channel 3:	145.890 MHz
Uplink channel 4:	145.910 MHz
Uplink data format:	Manchester-coded FM, 1200 baud, AX.25
Downlink channel:	435.910 MHz
Downlink data format:	PSK, 1200 baud, AX.25
Downlink power:	1 Watt rms
Required uplink power:	100 Watts eirp

Table 2. Mode JD parameters.

Uplink frequency:	1269.675 MHz $\pm$7.5 kHz
Uplink data format:	2400-baud biphase PSK, AX.25 protocol
Required uplink power:	650 Watts eirp
Downlink frequency:	435.675 MHz
Downlink data format:	400-baud biphase PSK, AX.25 protocol
Downlink antenna gain:	10 dBi, RHCP

Table 3. RUDAK parameters.

WHAT'S IN A NAME?

The casual observer of the amateur satellite scene might get the impression that there are several more amateur satellites than there actually are. Depending on the vintage of an article—i.e., whether the spacecraft under discussion had been launched at that time or not—you may see a satellite called by a name other than the one you're used to. For example, UoSAT-A, UoSAT-1, and UoSAT-OSCAR-9 are all the same craft.

Any really good name will contain at least one acronym. OSCAR stands for Orbiting Satellite Carrying Amateur Radio. AMSAT refers to the name used by the Radio Amateur Satellite Corporation, headquartered in Washington DC. The AMSAT moniker was picked up by other national groups as they formed: e.g., AMSAT-DL (Germany), AMSAT-UK (England), and JAMSAT (Japan). The original AMSAT, based in the United States, is pondering the bylaw changes necessary to become AMSAT-NA (North America). AMSAT (no suffix) would then refer to the international community of radio amateur satellite enthusiasts. UoSAT means University of Surrey Satellite, referring to those satellites designed and built by radio amateurs and others at the University of Surrey in Guildford, England. These acronyms are strung together to form a satellite's name.

Satellites carry different names pre-launch than they do post-launch. There are several reasons, perhaps one is for the same reason you say "break a leg" backstage before the curtain goes up. It also keeps order of manufacture separate from order of launch, for those lucky enough to have more than one in progress at a time. Satellites are usually lettered before launch, and numbered after. This is true in industry as well; LANDSAT-D became LANDSAT-4 after reaching orbit. Spacecraft that don't make orbit don't get numbers. The ARIANE launcher for AMSAT's Phase-3A spacecraft failed shortly after liftoff, and it never became OSCAR-9. The second Phase-3 model built, Phase-3B, became OSCAR 10 because UoSAT-A beat it into orbit. Simple, see?

One other confusing factor is UoSAT-2 versus UoSAT-OSCAR-11 (abbreviated Uo-11). These are both post-launch names for UoSAT-B, and both names are used at various times in various places. The Uo-11 mission patch says UoSAT-2, the QSL card says UoSAT-OSCAR-11. Keep on your toes and you won't get caught.

A possible confusion on the horizon is Japan's JAS-1. Will it remain JAS-1 once on orbit? Will they want it to have an OSCAR number, and will it be abbreviated JO-n? Only time will tell. It seems a safe bet that Phase-3C will get a name in the AO-n series.

The Russian amateur satellites are usually given numbers In the RS series. See page 3-8 in reference 1.

It's easy to imagine how just listening to the downlink will provide interesting information on communications conditions—worldwide QSOs as well as general bulletins. Since the design philosophy of the communications links has been directed toward supporting individual users, it is recommended that stations make normal QSO-type contacts rather than set up gateway stations to transfer large blocks (e.g., file transfers, mailboxes). As the satellite is visible for long periods of time per orbit, the QSOs can occur in real-time rather than being handled in a store-and-forward fashion.

Ground-Station Digital Requirements

A RUDAK ground station (see Fig. 4) makes use of a regular packet terminal node controller (TNC). For the majority of the TNCs—e.g., TAPR TNC-1, AEA PKT-1, or Heath HD-4040—the only software modification required is an updated EPROM to handle a hardware bug in the WD-1933/35 HDLC controller. Otherwise, only a PSK modem for 400/2400 bps has to be connected to the external modem jack in the TNC.

Other TNCs, such as the Kantronics Packet Communicator, or various software solutions are unfortunately not suitable due to the software and/or hardware restrictions. The TNC must be capable of operating full duplex at different transmit/receive baud rates and support the connection of an external modem. The TNC-2-type TNCs need to have a wire added to permit external data clocking.

Besides the normal equipment, a RUDAK User Interface is required, which is under development by the RUDAK group and AMSAT-DL. This interface consists of an upconverter (which translates a 2m signal to 24 cm and modulates the carrier with 2400-bps BPSK) and the AMSAT-AFREG, the BPSK demodulator for the 400-bps downlink. Additionally, various buffers and controls for switching the different signal paths and a power supply are needed. The various schematics, especially for the AMSAT-AFREG and the upconverter, will be published by AMSAT-DL when the design is completed.

RUDAK Hardware

How does RUDAK work? RUDAK is a nonlinear transponder, which is totally separate from the linear L-band transponder and its associated agc level, even though the rf and i-f stages are housed in the mode-L transponder. The BPSK demodulator, the processor unit, and the power conditioning unit are installed in a separate housing, consisting of two chambers. Photo E shows the processor unit side of engineering prototype model #2; Photo F shows the wire-wrap version on the test bench. At the time this article was prepared, the flight version had just been completed and tested, prior to shipment to Golden, Colorado, for satellite integration.

What kind of hardware is used? The center piece of the RUDAK experiment is the processor. Its structure resembles an 8-bit home computer with a 64K addressing range. The CPU, a 65SC02, is a CMOS version from the well-known 6500 processor family. The RAM section consists of 56K, organized as 7K x 8K.

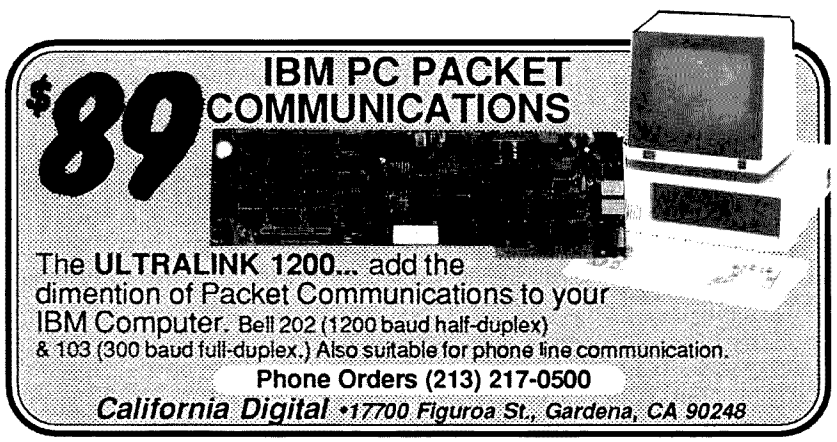
Out of all of the various new intelligent communications controllers, the well-known Z80-SIO (84C40) was selected for the AX.25 interface, as it was the only one available in CMOS when engineering work began. A second interface uses a 65SC22 VIA to provide data and program exchange with the satellite's main computer.

The ROM operating system contains a minimal operating system, consisting of the relevant routines needed for processor initialization prior to loading the main operating system, including RAM tests and initial telemetry. This arrangement assures the independent programmability of RUDAK, even in orbit. The main operating system is a variant of the IPS operating system, developed for OSCAR-10 by Dr. Karl Meinzer DJ4ZC. Measurements indicate that the power consumption of the entire 64K computer will be considerably less than 500 mW!

By the time this article is published, many steps will have been performed to prepare RUDAK and the satellite for launch, including thermal vacuum testing, vibration testing, and system performance testing. Photos G and H show a few members of the RUDAK team from Munich, West Germany, at work.

Where do I get more information? A user manual is in preparation, which will contain complete user information, such as schematics and parts lists to build the special equipment required for RUDAK operation, operating guidelines, link parameters, and access procedures for the robot modes. Various AMSAT-DL and AMSAT-NA publications will carry information on RUDAK. The Uo-9 and Uo-11 spacecraft will carry current information as the pre-launch, launch, and checkout activities occur.

WRAPUP



If you are interested in digits in space, 1986 should be a banner year. If you are interested in passing data through the network, you should be aware that in the future, much of the DX traffic will pass through the satellites discussed here. For the most in-depth coverage of the amateur satellite program, join one of the AMSAT organizations worldwide and get their journals. Come on up! ■

Connect Alarm!

Let your TNC call you when it has something to say.

The packet mode of communication is becoming one of the most popular phases of amateur radio. One of my projects upon recent retirement was to get a packet system assembled and in operation, initially on VHF, then expanding it to HF capability.

One of the first packet-gadget things I built for my TAPR-1 TNC was a connect-alert unit. The idea for this gadget was given to me by Gervie W7FEN, who already had added it to his system. I built the little unit and it worked as expected. A few months later, Louie WA7BHK bought an AEA PK-80 TNC, and having seen my system, asked me if the connect-alert portion of that circuit could be used on his TNC.

A look at the circuit of the PK-80, which is a clone of the TAPR-2 TNC, revealed that the desired signals and power for the alert circuit could be taken from the DB25 (J1) connector on the rear of the TNC. No internal connections requiring opening up of the PK-80 were necessary. A connect-alert unit was built and hooked to Louie's TNC. The little beeper sounds off as designed whenever there is a connect to his system.

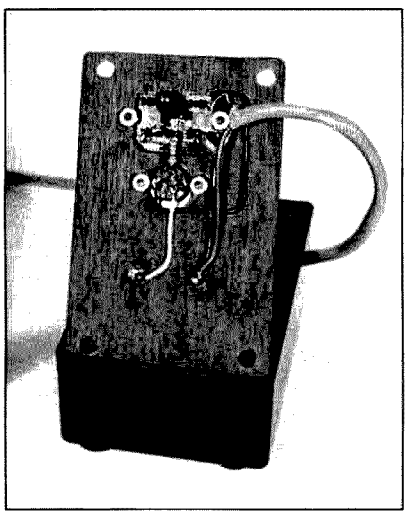

Photo A. Inside the connect-alert unit.

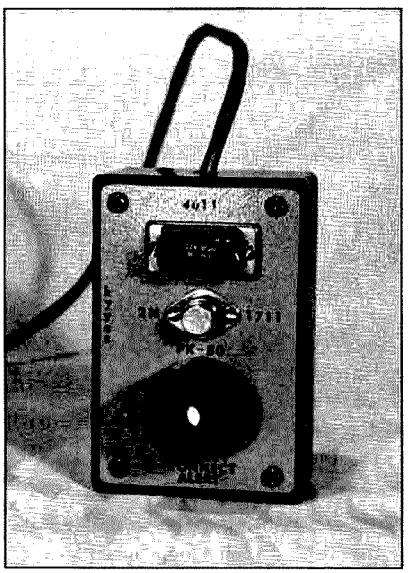

Photo B. The completed alarm.

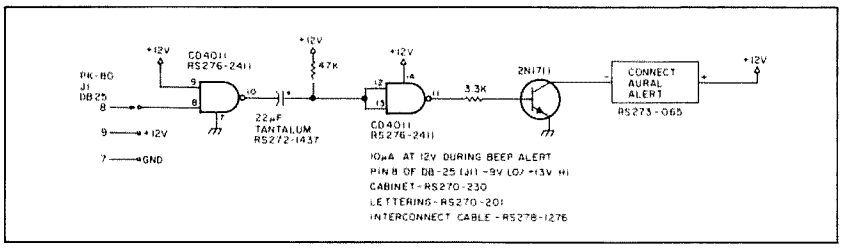

Fig. 1. Schematic diagram.

Construction

The little Packet Connect Aural Alert unit was built in a small plastic cabinet. The metal cover was replaced with a piece of Formica cabinet-top material to reduce the possibility of unwanted short circuits. The plastic sonic beeper unit was attached to the cover by a dab of epoxy cement. A small terminal lug strip was attached to the underside of the plastic cover to support the few components used in the circuit. (Be sure to observe the proper polarity of the tantalum condenser and the sonic alert unit when connecting them into the circuit.)

Testing

The circuit of the connect-alert unit is easily bench-tested by applying 12 volts to the proper points and then momentarily connecting pin 8 of the CD4011 to ground, then to plus 12 volts. If all is wired correctly, the beeper will sound off with a short shrill burst of sound.

Operation

With the alert unit control cable wired properly to pins 7, 8, and 9 of the DB25 (J1) connector for the PK-80, at power-up of the PK-80 a short beep should be heard from the unit. This is a quick self-test feature of the system. Each time thereafter when a connect is made with another station the aural alert beep will be heard.

This packet gadget should be of help to those getting set up for the latest and most interesting world of packet communication. Best of luck, and CWUL (Connect With You Later). ■

Survival Training For Mountaintop Digipeaters

A ROM with a view.

It was mid-afternoon, late by mountaintop standards. From the ground, the clouds seemed motionless. The air was moist, still, and quiet. Up on the tower it was another story. Greg WB6ASR, leaning unsupported 50 feet above the ground, was constructing an antenna on the tower from parts pulled from his parka pockets. Fifty-mile-per-hour gusts squeezed the moisture from the cloud onto anything they touched. It was cold, it was wet, and we were late.

Later, with the antenna constructed and coax routed, we repaired to the building to continue testing the digipeater we were fixing. Finally satisfied that the digipeater was operational, we packed up the wattmeters, the portable computers, and the multiple toolboxes. We had just installed a brand new radio and new switching power supply. We had upgraded the digital hardware and installed the latest version of the digipeater software. And, as a final precaution, we had installed a watchdog timer, which would perform a "hard" reboot of the digipeater every 15 minutes. Any single improvement would have been enough; we did them all.

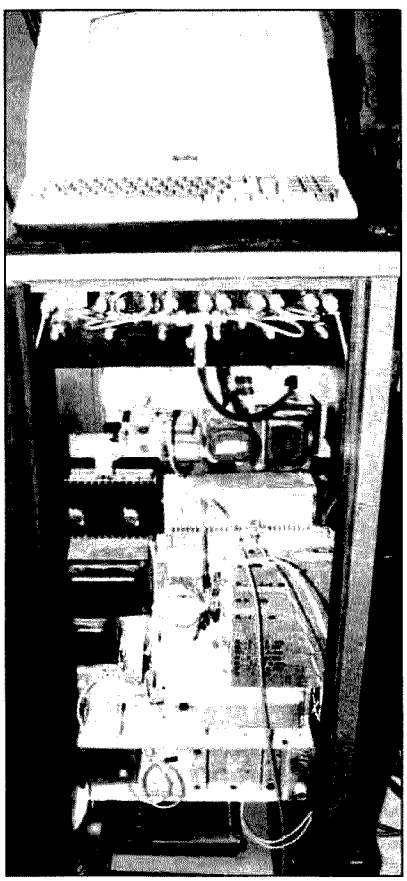

Photo A. Well-dressed mountaintop equipment racks now sport computer terminals. This digipeater requires 5-1/4" of this equipment bay.

Photo B. A two-meter pass cavity is much like an antenna: If it is small enough to be convenient, it is too small. This one is 24" tall and 9" in diameter.

It was very late when we finally arrived home. No matter. We *had* to test the digipeater, now so far away. It was still there. It worked well.

As the uptime data accumulated over the next few weeks, it became obvious that we had done well. This was another "zero-downtime" site. Then, three weeks later, a seven-minute outage. The next day, another. Without pattern, without reason, and a five-hour drive from civilization, our digipeater was hiccuping. Without the watchdog timer, it would have gone down for good.

Most users were unaware of the difficulties at our digipeater. It was heavily used and seemed reliable. Only we saw the downtime statistics piling up; we began to plan our next trip to the hill.

Introduction

This article describes a network of mountaintop digital repeaters covering the state of California. This network was installed by our radio club, the W6AMT ARC, in early 1985 and has been in continuous use ever since. Fig. 1 is a map of the system showing the relative locations of the major sites and California population centers.

This article is divided into three parts: the goals of the network, the trials and tribulations of putting (and keeping) the network

components up, and the direction the network is taking.

Mountaintop Digipeater Networks

Our first step in designing our communication network was to define the goals of the network: We wanted to move data reliably, expand the network as technology progressed, serve the major population centers in California, and have fun building it.

The first part of the network structure to plan was the locations of the digipeaters (digital repeaters). These locations were dictated by the major population centers in California. The proximity of the digipeaters was determined by their range and the desire to have as little overlap (mutual interference) as possible. As soon as the ideal locations for network digipeaters became settled, site acquisition started.

The hardware for the network was selected with a design goal of zero-downtime. Previous experience in mountaintop remote-base and voice-repeater equipment was a good start: There was no desire to invent anything if an acceptable solution was already available. Many industry professionals were consulted and potential pitfalls were identified in advance. Unfortunately, there was little real experience in combining mountaintops, computers, and radios, so we fell somewhat short of zero-downtime.

Finally, we had to choose the software for the network. It was not thought to be an issue at first but has become the major issue within the community. Network software will be discussed in greater detail later in this article and in other articles in this issue. Additionally, a bibliography is included for the serious digipeater student.

Selecting Digipeater Sites

There are several methods that can be used to cover California with reliable data communications. They fall into two generic categories: low-level digipeaters and high-level digipeaters.

We describe a digipeater as "low level" when it is planned to have a range of about 20 miles—the range of most "home" digipeaters. Building an amateur digital communications network with many low-level machines has several advantages. Since by implication such a network would be composed primarily of home stations, the cost to our organization would actually be less; all we would have to do to get the coverage we wanted would be to "find" the stations that were in the "right" places. Easy. This network would also be *much* easier to maintain because each node would take care of itself.

There are also some disadvantages. Sometimes there are *no* people in the gaps between population centers. Other times there are too many people to allow "picking" one without everyone else asking, "Why not me?" Additionally, a low-level digipeater network has a fatal flaw: It requires more "hops" in any long path connection than the packet-radio lingua franca, AX.25, will allow. Eight digipeaters are all you can request, and there were too many miles between major population centers for this number to be sufficient. The design goal was to have Portland, Oregon, connect to Los Angeles with those eight hops. Greater distances were to be handled by using mailboxes along the way.

Another failing of a low-level digipeater network is that paths would always be changing; since the network depends on many

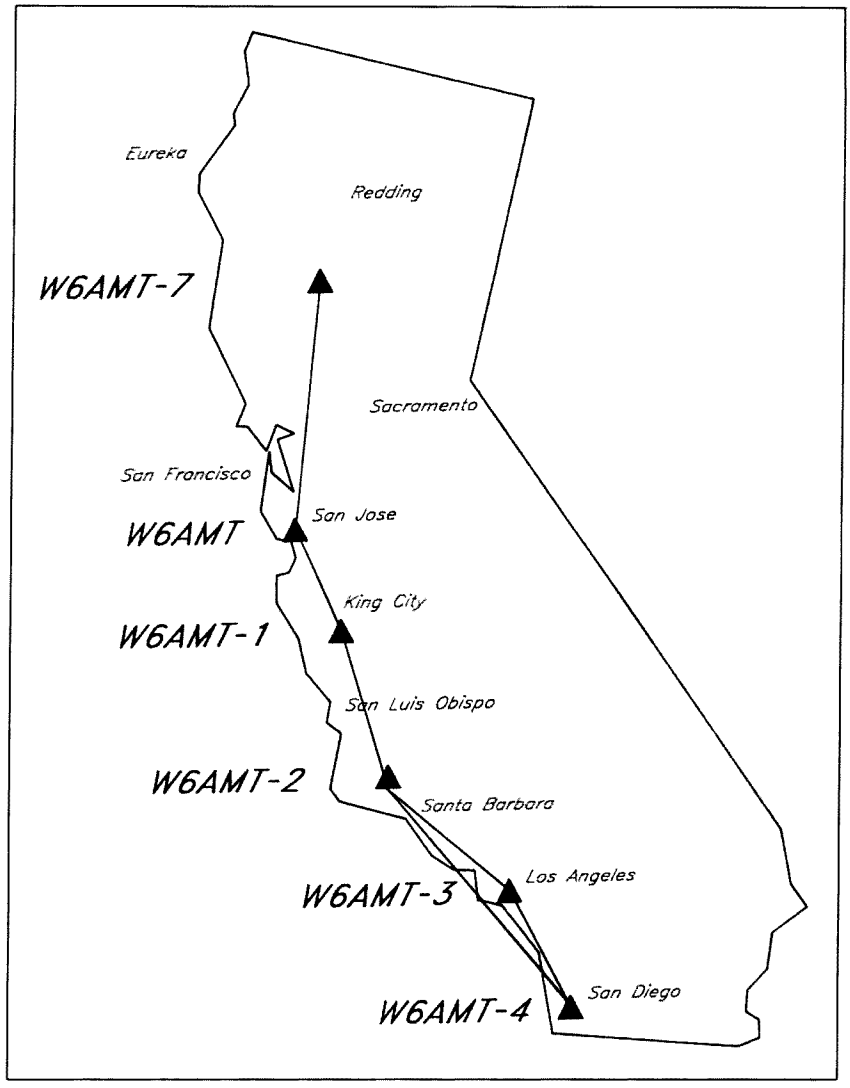

Fig. 1. The AMT Packet Radio Network on 145.01 MHz as of May, 1986 (diagram by WB6ASR).

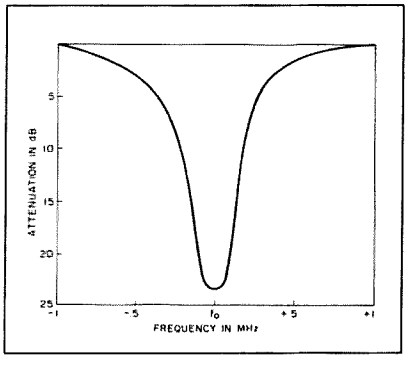

Fig. 2(a). Notch-cavity response curve.

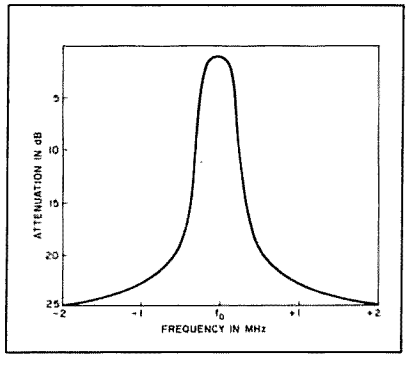

Fig. 2(b). Pass-cavity response curve.

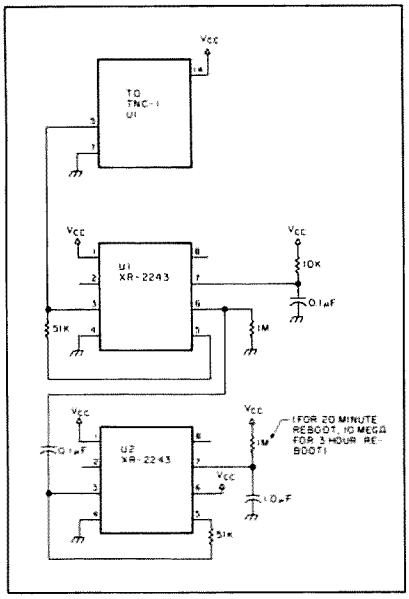

Fig. 3. Remote-site watchdog timer.

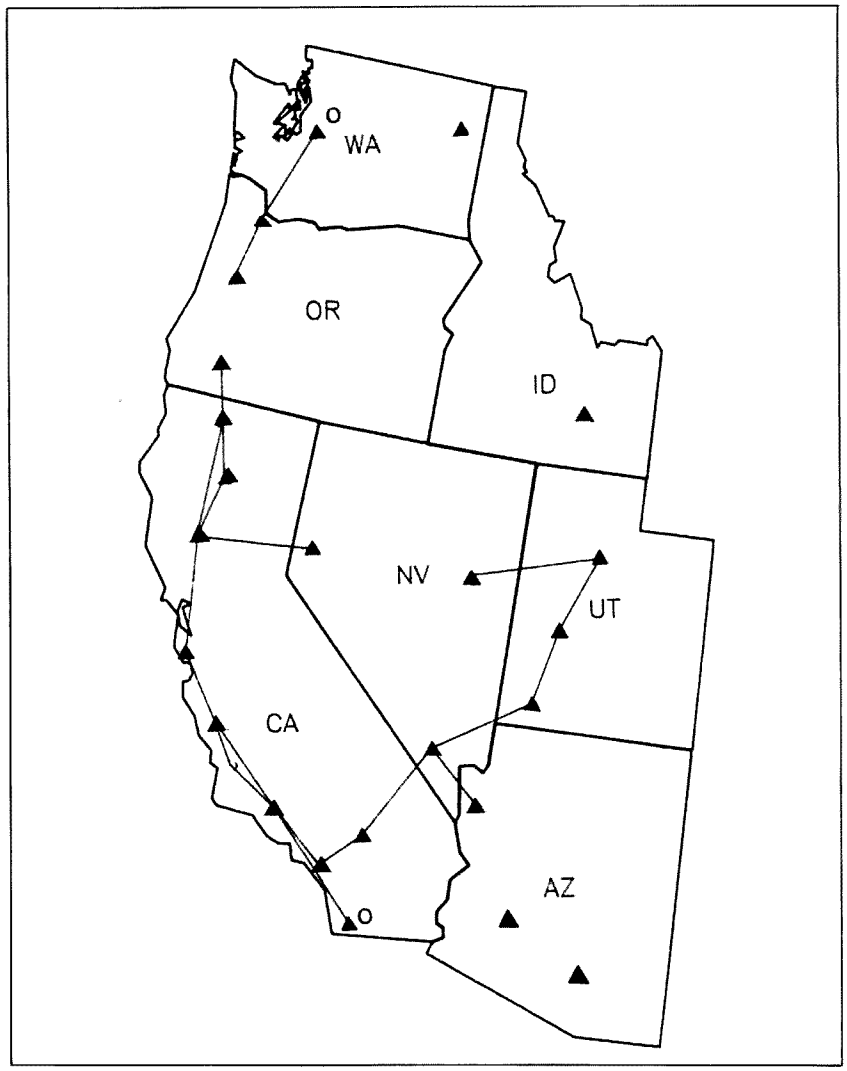

Fig. 4. WESTNET as of May, 1986. Triangles represent digipeaters and circles represent mailboxes (diagram by WB6ASR).

home stations, there would be a high turnover as the operator got bored and turned his station to other interests. Therefore, constructing a network for California from low-level digipeaters was eliminated early in the planning process.

The network topology we eventually chose was a network composed almost entirely of high-level digipeaters. "High level" is defined here as locations suitable for wide area coverage of the kind employed by voice repeaters. These sites were generally about 4,000 feet (more than 1,000 meters) in elevation and located so as to cover the population centers we desired.

Most of the advantages of the high-level digipeaters are obvious: There was *less* hardware in the network, fewer hops were required to cover a given distance, and, since the hardware and locations would be managed by our club, the network topology would be stable.

It is a truism within present amateur digital networks that the data throughput on even a slightly loaded network goes down *very* rapidly with an increasing number of hops. Most connections are futile if they contain more than four digipeaters. Thus, the farther you can go between digipeats, the farther your "digital range."

There are, of course, disadvantages with the high-level network. There is the problem of maintaining hardware and software on mountaintops, which are sometimes a day's drive from civilization. Additionally, it turned out that computers and mountaintops do not get along very well together.

Hardware Issues

Because high-level digipeater sites tend to be placed well away from civilization, hardware maintenance must be accomplished after a long drive. Problems can be minimized if the hardware is packaged and tested very thoroughly in a configuration that closely resembles the final one.

Another site maintenance difficulty that became obvious was that we were trying to adapt hardware and software into a system in which none of the component parts were designed to work. One would expect to have some problems where corners were cut as an acknowledgment of budgetary constraints. But who would ever expect software that is "solid" at a home station to misbehave when used for a hilltop digipeater? Trying to foresee all difficulties in advance is futile; we discuss those we encountered and invite correspondence.

When we put up our first digipeater, it was basically just a transported home station. We had some experience in the environment of a mountaintop and figured that we knew what the radios would do. As for the computer stuff, "What could go wrong? After all, it's digital!" Radio amateurs, however, have had little experience with hilltop computers.

The fact that we have a network up that carries as much traffic as it does shows that you do *not* have to go out and buy expensive commercial equipment of possibly limited availability; you merely should be aware of the environment your equipment is going to be immersed in. Remote locations are a much more hazardous environment than we at first thought—but almost anything can eventually be managed if anticipated.

We Picked Mountaintops

Having looked at the pros and cons of building a mountaintop digital communication network, and despite the fact that there was no one else in California to "connect" to on 145.01 MHz, we decided to put our hardware up. The digipeaters went up one by one over a period of about three months. This turned out to be fortuitous timing as it corresponded to some very explosive

growth in the packeteer population within California.

That the approach of placing digipeaters high and far apart was a successful one was immediately apparent. Single-hop QSOs covering more than 200 miles became commonplace. Other states became workable for the first time over paths that were unknown before this time. An example of this was the connection in early March, 1985, of Jack WA7DIA using his WA7DIA-1 digipeater in Reno, Nevada. Previously unheard-of distances became an everyday occurrence. Packets were "heard" in Oregon and in the mountains near Las Vegas. The outcome was obvious to those with foresight: network saturation.

Some disadvantages also became apparent. With a single digipeater in sight of so many stations, users started to wonder why they couldn't get digipeated. The common complaint was, "Why doesn't the digipeater hear me? I'm running 200 Watts." The digipeater itself usually ran some tens of Watts (which was plenty), so what *was* the problem?

We wandered up to the hill for a prime-time look at the problem. We hooked up our terminal and sat back for an enjoyable operating session. When we turned it on, we were amazed: We saw nothing but continuous packets going by. People trying to use the digipeater, people using other digipeaters within range, people talking to people simplex. People and more people. It was a wonder that anything got through at all! We called this the "white lightning" effect and are still wondering what to do about it.

Another problem that showed up early on was the number of "Dufus" packets. Dufus is that brand new packeteer. He is still trying to figure out all the settings and options on his latest TNC. You gather he is obviously a little lost from the things he is saying to others who try to contact him. He has lots of company. I guess it is to be expected since packet radio is still a very new mode. There were so many problems with Dufus and his friends that sometimes our digipeaters carried beacons outlining suggested operator settings for the TNCs "out there."

Mountaintop Characteristics

Our club has many great memories of mountaintops. We spent many VHF/UHF contests atop hills. The weather got a little chilly but it was never terrifying. Putting hardware up and leaving it up is quite different. The benign rocks and trees you see during the day when you are tightening bolts and routing coax become downright hostile when you turn your back. Exposed hardware does not merely break, it disappears.

Weather

The primary villain is wind. If the weather gets cold, ice and snow will also add to the misery your hardware must undergo. Ice increases the wind load, while snow, if deep enough, will make a shambles of your swr. Coaxial-cable routing should be done carefully. If routed where it will swing in the wind or be used as a support by someone else working on the mountain, it will not last. The last thing to remember is to have plenty of weatherproofing putty on hand to seal the weather out at the coaxial-cable entry point to the building.

Problem	Solution
NOVRAMs	PROMs
v2 transfer	Better software
Drift with temperature	Better pots for the TNC
RFI	Toroids, filters, chassis sanding, grounding, 9913 coax, bypassing, etc.
EMI	Ditto
Relays	IC-28Hs, IC-27Hs, GE-MVPs, Motorola Moxys
Sabotage	Locked cabinets—remember to lock up cavities
Desense	Cavities, antenna placement, coax routing, prayers

Table 1.

Mountaintops display extremes of temperature—sometimes more than 100 degrees in a day. Hopefully, the shelter housing the digipeater moderates the outside temperature somewhat. There will be both short- and long-range temperature swings to endure.

One problem we found with some of our digipeaters was that the modem tones produced by the TNC drifted. The drift was compounded by the changes in humidity accompanying the temperature changes. After fighting it for a while, we gave in and replaced the cheap carbon single-turn pots that came with our TNCs with 10-turn wire-wound pots. The drift is still there, but the TNC can go years without recalibration.

Before we get off the subject, it should be mentioned that heat, being the great killer of electronic equipment, should not be allowed to build up. All the sites should have exhaust fans that are placed to minimize intake of dust. Mountains are quite dusty.

Power

Another topic unique to hilltops is the kind of power you are going to have to use for the digipeater. The power that gets supplied to the top (if you are fortunate to have commercial power supplied to the site) arrives after a long journey. If you put your trusty power-line monitor on ac, you would get a picture of chaos. Power dips, voltage surges, and lightning-induced peaks all are trying to get through your power supply and kill your digipeater.

If the hill supplies battery backup that someone else has made operational and is maintaining, and you are invited to use it, by all means, go ahead. However, if you are thinking of adding battery backup to your digipeater, realize that there are many costs associated with batteries. They take up a lot of space, they require maintenance, and they are expensive. On the other hand, batteries might be the only way to get reasonable uptime from your digipeater.

Some mountaintops have an emergency backup generator. This is usually a beast of a generator that is set to come on a given time after the commercial mains drop out. This power source has all the problems of commercial power with the added feature that the line frequency can vary. This is a problem for some types of switching power supplies.

Another topic worth covering while discussing digipeater power sources is the trade-off between switching and linear power supplies. Switching power supplies operate more efficiently, weigh less per Watt, and occupy less space. Because they are more efficient, they generate less heat. Thus, all things being equal, switching power supplies increase system reliability. The trade-off is that "switchers" cost more, and the less expensive ones are sensitive to power-line quality. We use switching power supplies in most of our sites primarily for saving space and have been very satisfied with the resultant system reliability.

Electronic Environment

One aspect of mountaintop operation that is not confined to mountains alone is the number and variety of rf generators that can be located very close to the digipeater. Some sites have very high power transmitters operating continuously. This has the advantage of presenting a known environment to operate in, but also the potential disadvantage of producing very high rf seemingly everywhere. Other sites have a larger number of much lower powered transmitters, which operate at irregular intervals. It is often difficult to perfect the digipeater in this type of environment because the problems occur when two or more of the co-located transmitters transmit simultaneously.

The best method we have found for obtaining reliable rf performance at the digipeater is to utilize a "pass cavity" or two between the digipeater radio(s) and the antennas. This is possible because the digipeater is a simplex device: It operates on a single frequency for both transmit and receive. A properly adjusted pass cavity blocks all other non-harmonically related rf energy from the digipeater radio's "front end." It has the added benefit of attenuating any spurious energy produced by the digipeater. This makes the packet-radio box a good neighbor. Some sites have a particularly tough problem with co-located transmitters that are also very close in frequency. This type of problem can be solved through the use of a "notch cavity," which has its notch set to the interfering transmitter's frequency. A good quality cavi-

ty can be quite sharp, as indicated by Figs. 2(a) and 2(b). It is one of the best investments anyone considering a high-level digipeater can make.

Operating a TNC in close proximity to a great deal of rf energy was not one of our design considerations. We had problems with rf getting into the TNC and causing anomalous performance. We had already put the cavity on the radio, so other radios were not bothering our TNC—our own transmitter was. And it was a hassle. Everything would work perfectly until we tightened the last screw. Since we could no longer test the TNC ourselves (because we had to disconnect our terminal), we had to depend on the reports of others. They would say that the TNC was "loud, but it didn't transmit very long." We named this problem the "short problem." It turned out that when our TNC got a large enough dose of our own rf, it would transmit only quarter-second bleeps of bogus data. This was eventually cured by bypassing the TNC leads (mostly power leads), putting toroids on the leads to choke the rf, and, as a temporary expedient, reducing the power out of the digipeater transmitter.

EMI and RFI

One of the problems in operating radio equipment near computers is that computers are "noisy." They generate noise and spurious signals all over the spectrum. This problem has the name electromagnetic interference (EMI). It sometimes seems that most of the popular TNCs had one of their loudest birdies right on the frequency we chose to put the digipeater on. On either side of 145.01 MHz, everything was quiet, but tune to .01 and there was an S9, slightly off-channel signal!

There is no easy solution to this. The signal was there and didn't want to be moved. We turned to the books on the subject, which proposed all sorts of solutions. We tried them in order, each improving the situation a bit, until we were satisfied.

The most important step in reducing the ill effects on our radio from the signals being generated by the digital circuitry in the TNC was to bite the bullet and shield the TNC from the radio. This meant that the TNC enclosure had to be made into an rf-tight box. After scraping the paint off the box (to better the electrical contact) and putting more screws into the sides, we tackled the power and signal leads coming out of the TNC enclosure. One last tactic was to use high-quality, well-shielded coax. We wanted signals to enter the radio only from the antenna, not to come into the coax unintended.

Equipment Selection

Mountaintop digipeaters are no fun if they are down, and they are down longer if they are hard to maintain. Several sites are far enough away from the home QTH that the distance we had to travel became intimidating. Anything we could do to forestall a trip to the hill was worth the effort. Equipment was selected (after the first digipeaters taught us the hard way) for reliable service in digipeater use. Digipeater use is quite different from most other services. Its characteristics are low duty cycle (the average packet is a second or so long) and a large number of transmissions per unit time. A busy packet channel will average more than ten packets (transmissions) per minute...all up and down the state...thousands per day.

The equipment of choice is solid-state throughout, has no mechanical relays anywhere in the PTT (push-to-talk) logic, recovers unaided from vagaries in the power supplies, is capable of being well (enough) shielded, and reboots itself if the computer goes down. Suitable equipment is available in the amateur radio or commercial radio industries.

The only piece of hardware that we could not buy off the shelf and either use directly or modify for use was the watchdog timer mentioned earlier. We built ours to be "field installable" on a small PC board that connected to the TNC via a ribbon cable. We simply removed U1 (of our TNC-1s) and plugged our board in. The reset time was set to reboot fairly often. The thought was that if we rebooted every 15 or so minutes, we would lose a packet due to rebooting less than one tenth of one percent of the time. Fig. 3 is a schematic of the watchdog and has details of operation and installation.

Software Challenges

Not all the problems confronting the mountaintop digipeater are hardware. The rest are software or software related. The protocol that all TNCs "speak" to each other is called AX.25. It was derived directly from an internationally established digital communication protocol, X.25. This protocol is specified in two versions with version two (AX.25 v2) being somewhat more powerful. As users of the digipeater system started to use v2, it was discovered that the digipeaters in the network would not digipeat the v2 packets. We needed a bug fix. After casting about for some months, we got lucky and acquired some PROMs with software that would digipeat v2 packets. Some TNCs still being produced cannot handle AX.25 v2 packets. Be careful if you are planning a digipeater.

The only other software-related problem within the scope of this article is not really a software problem at all. It turns out that the TNC-1s we were using would "forget" their own callsign. The callsign information is held in a nonvolatile RAM, in which the user customizes his TNC. Ours became volatile. We joked that NOVRAMs did not work above 2,000 feet, but the real culprit was the TNC itself. A design error was occasionally corrupting the NOVRAM. The good news was that it happened only when rebooting. The bad news was that our digipeaters were being hard-booted up to 50 times a day by their watchdogs. The solution turned out to be straightforward: We "blasted" the digipeater call and other particulars into the PROMs that held the software and did not use the unreliable NOVRAM.

Table 1 lists most of the problems we encountered and the solutions we implemented. The solutions are not perhaps the most elegant, but they are guaranteed to work.

Future Direction for High-Level Networks

The following is a subjective discussion of some future directions amateur digital communication networks will be taking:

- The mountaintop nodes of future networks will have much more "power" than today's meager digipeaters.

Several trends and facts will drive the mountaintops to provide many more user services than they do now. Any attempts to leave the complex stuff on the ground invariably require links to the hilltops. These links are sources of error and network failure. Keeping the complex stuff on the mountain eliminates a lot of hardware; network reliability is the prime driver.

- These will become dual-port and then multi-port digipeaters.

Dual-port and multi-port digipeaters are

GLOSSARY

Connect	A situation in which both you and the station you are talking to are in synchronization. His computer is talking to your computer, and all you see is error-free text being printed. Can be several hops.
Digipeater	Digital repeater. Receives data packet over the air and decodes the packet to see if retransmission is requested. If so, the digipeater retransmits the data.
EMI	Electromagnetic interference—generic term used here to describe interfering signals that are unintentionally passed around your equipment.
Hops	Digipeater "relays."
LAN	Local area network—those operators who can link to you through the same digipeater.
Link	See connect.
Packeteer	Packet radio operator.
RFI	Radio frequency interference—generic term for the situation in which your radios are causing malfunctions in other equipment.
TNC	Terminal node controller—the box between your radio and the computer terminal. Contains a computer that performs the retransmission and "link maintenance"—tries to synthesize an error-free path.
User	An operator who believes everything you tell him.
WAN	Wide area net—all the operators who are capable of being connected to.

necessary to allow the LANs that have developed on separate frequencies (and perhaps that have separate digital protocols) to interconnect. HF, satellites, and other developing communication technologies are going to want to be interconnected.

• We will see common use of hilltop mass-storage systems.

There is just too much flux in the software amateur networks are running to update your system with a new set of PROMs with every new software release. Uploading data from the ground is the preferred method of updating both digipeaters and geosynchronous satellites. The former are little more accessible than the latter. Additionally, there is much data that will be collected by the mountaintop digipeater for its own use. Winchester drives on mountaintops are just one cost-effective solution.

• There will be several different protocols in use in the near future. Therefore, the networks are going to have to support multiple protocols to be maximally useful.

There is no dearth of processor power these days. There is no excuse not to put every protocol that will fit into the computer's memory onto the hilltops.

• Other resources that mountaintop digipeaters (or digipeaters in general) will be providing users are mailboxes, execution servers, and data base servers. This is just a further economy of overall network resources.

Future software, though more complex, will be much more reliable. One of the frustrations of present TNCs is that supporting the software by adding features or squashing bugs is very difficult. Software that is easy to support will be used. Support includes available source code, relatively common support environment, and available expertise in the details of said software.

Summary

When we first planned a statewide network, the task to be accomplished seemed obvious: move data reliably. As our thinking progressed, additional goals became clear. There were other (more or less) compatible digipeaters to link to. There were problems with overlapping coverage and propagation-dependent paths. There was (sigh) intentional interference. There were changes to the underlying AX.25 protocol which necessitated software upgrade to the hilltops. There were plans, plans, and more plans. The future had to be accommodated; the network was in danger of being obsolete before it was completely operational.

Now, the network is up and there are many other groups and individuals linked together. Fig. 4 illustrates the extent of the Western United States packet-radio network (commonly called WESTNET). Development proceeds at a rapid pace (for amateur radio). One thing is certain: Tomorrow's networks will be more fun than those of today. ■

Beyond Level Two

High-level networking comes to packet radio.

Most of the packet articles in this issue of 73 *have been aimed at non-packet users or new packet users. A few were targeted for second-year students. This article is for the user who is ready to take the advanced packet course. It discusses issues at the center of the next round of technical development. If you are at the advanced level, read on and get ready to help out. If you aren't quite there yet, scan through and start to pick up some of the terms and concepts. If this issue was your first exposure to packet radio, take heart, this space could have been four more pages of Never Say Die.—NK6K*

It is an exciting time for amateur packet radio. In this young facet of our hobby, things happen fast. Just as the new packeteer is getting started, he or she is immediately bombarded with all sorts of arcane buzzwords like "protocols" and "layering" and "level 3," spoken by people who always seem to be arguing passionately with each other, usually about things like "datagrams" and "virtual circuits." The poor neophyte must think: "It was bad enough when computers came to ham radio, but this is *communications*, a subject I'm supposed to know something about!"

In this article I hope to dispel some of the mysteries surrounding the new developments in packet-radio protocol. This *is* communications, so there really isn't much that's fundamentally different from what you already know from being a ham. Computer networks are nothing more than automated traffic nets, using computers instead of human beings to move messages around. Of course a computer, being both faster and dumber than you or I, can't (and shouldn't try to) do everything in exactly the same way as a human. This often has quite an effect on what uses are (or aren't) practical. But the underlying ideas are the same, and I think you'll easily see them.

The Story So Far

As has long been the case with CW, phone, and RTTY, packet radio has standard procedures for initiating and terminating QSOs, and for exchanging information during the QSO. In computer lingo, such procedures are called protocols. The only real difference is that packet-radio protocols are much more formal than the protocols for, say, an SSB rag-chew. This is because packet-radio protocols are carried out by computers, which lack human traits—such as common sense. Every little detail, no matter how "obvious," has to be spelled out because computers will do exactly what you *tell* them to do, not necessarily what you want them to do.

Almost all amateur packet-radio work is currently done with what is commonly known as the "AX.25 Link Layer Protocol."[1] Virtually all the packet Terminal Node Controller (TNC) boards now sold have AX.25 programmed into them. AX.25 began life as the link-layer portion of the CCITT X.25 protocol.[2] X.25 is the protocol used by customers to access packet-switched public data networks operated by common carriers such as GTE Telenet and Uninet in the USA, and by the Postal, Telephone, and Telegraph (PTT) agencies in many other countries. The link-layer portion of X.25 is also known as LAPB (Link Access Procedures Balanced). LAPB itself belongs to a class of link procedures known as HDLC (High-level Data Link Control). HDLC was originally developed by IBM, and it is now an International Standards Organization (ISO) standard. (To quote Tanenbaum: "The nice thing about standards is that you have so many to choose from; furthermore, if you do not like any of them, you can just wait for next year's model."[6])

HDLC is popular in the commercial world, and several manufacturers make integrated circuits that support it. HDLC is a *synchronous* protocol; that is, it lacks the start and stop bits that surround each character in ordinary (asynchronous) RTTY and ASCII transmissions. This improves the efficiency of the transmission at the expense of slightly increased complexity.

As mentioned earlier, X.25/LAPB/HDLC is the protocol used on landline links into common-carrier networks. Since these links are "point-to-point" (i.e., they lack the one-to-many, "broadcast" nature of radio), LAPB lacks addressing. To make it usable on a shared radio channel, addresses (amateur callsigns) were added to LAPB, making AX.25. With this change, the shared rf channel became a true network, with packets implicitly "switched" among stations by virtue of the source and destination addresses always carried in each packet header. This is very similar to several commercial local area networks, the best known being Ethernet.[3] (Ethernet is often described as "packet radio on a cable.")

The underlying medium (coax cable or rf channel) is "stateless," that is, it "remembers" nothing from one packet to the next. Each packet must therefore contain all of the information necessary to get it to the proper destination. For this purpose, Ethernet and AX.25 both include full source and destination addresses in every packet, and the resulting packets are known as "datagrams." Since the notion of a "connection" requires something to remember who you are connected to, the endpoints have to do this themselves.

In Ethernet, connections (if desired) are left up to a separate, higher-level protocol; in AX.25, it is "built in" in the form of LAPB. AX.25 therefore consists of two halves: a lower "sublayer" that handles addressing on a packet-by-packet basis, and an upper sublayer based on LAPB that sets up a connection, retransmits packets when they are lost, and takes down the connection when it is no longer needed. It is possible to bypass AX.25's upper sublayer with the "UI" (Unnumbered Information) frame. UI frames are sent without regard to connections, guaranteed delivery, and so forth. Currently, the most common use of the UI frame is for broadcasting information (such as beacons) to all stations in a local area.

Why AX.25 Level 2 Isn't Enough

If the entire amateur "network" consisted of a common rf channel that allowed every user station in the world to communicate directly with everyone else (and assuming of course that this channel had enough capacity to handle everyone's traffic) our problems would be over. The closest we can come to this is a satellite channel. Even a satellite, though, can never see more than 1/2 of the world at any one time, has limited bandwidth, and requires specialized ground-station equipment. On the ground the problem is worse; only a tiny fraction of the stations one might want to communicate with are likely to be within direct VHF/UHF or even HF range.

Most networks in the world, not just the amateur ones, are like this. In order for most stations in the network to communicate, their

messages have to be relayed through intermediate stations, a practice familiar to hams from the very first days of amateur radio (and reflected in the second "R" in "ARRL"). The complications that result from this fact of life are what makes networking such a difficult, interesting, and/or lucrative (depending on your profession) problem. Problems such as routing (choosing one of many possible indirect paths through a web of transmission links), congestion control (alleviating or preventing traffic jams at "hot spots" in the network), and load sharing (getting the best use out of expensive investments) have occupied the minds of telephone company engineers, highway planners, and airline executives for many years. The amateur community is only now realizing the full scope of the challenges we face in building a practical, large-scale packet-radio network. Those who answer this challenge will find it a highly rewarding and educational experience.

As a temporary, partial solution to the lack of a universally accessible rf channel, AX.25 provides the "digipeater." This is a device that receives properly addressed packets and repeats them after a short delay, usually on the same channel. Digipeaters are very simple, stateless devices; they remember nothing from one packet to the next. Therefore, each packet to be routed through a digipeater must specify the digipeater's address. So we already have true networks out there, traversed by packets containing "source routes" (the list of digipeaters placed in each packet by the sender).

So AX.25 level 2 is certainly doing quite a bit more than its originally intended "link-layer" job. There also seems to be universal agreement that the current protocol by itself is just not up to the task. A network layer built solely out of digipeaters performs badly for the following reasons:

1. Acknowledgements in AX.25 are all end-to-end. If a packet is lost halfway down a chain of digipeaters, it must start all over again back at the source. While end-to-end acknowledgments are both necessary and sufficient to guarantee the *correctness* of a data transfer, it is obvious that performance can be very bad.

2. At present, digipeaters cannot automatically route packets based on destination addresses. As mentioned earlier, the sending station must specify in the packet the entire route to be followed. This can result in wastefully large packet headers, especially when a long chain of digipeaters is being traversed. Worse, the sending operator often does not know what digipeaters are available outside his local area, and even if he does he may not know which are the best routes to use. It *would* be possible to build a digipeater to route packets automatically based on their destination addresses. However, when routes change it is possible for the network to deliver packets in a different order than they were sent, and LAPB was never designed to handle this situation.

Digipeaters were intended as temporary stopgaps to provide connectivity until smarter "packet switches" could be built to replace them. The idea was that AX.25 level 2 connections would be established only between stations having a direct rf path, and that a higher-level protocol would be supported by these switches to relay actual user traffic. As everyone knows, the popularity of amateur packet radio virtually exploded before these protocols had a chance to be developed and tested.

Divide and Conquer

Before describing the work that is underway to build an amateur packet network that solves the problems associated with digipeaters, it is a good idea to review some helpful principles. A large, complex system (such as a computer network) is almost always more manageable when it is structured as a hierarchy. Virtually every organization with more than a few people (such as a business) is organized in this way, so this should be familiar to just about everyone.

"The nice thing about standards is that you have so many to choose from; furthermore, if you do not like any of them, you can just wait for next year's model."

Organizing systems into hierarchies is useful whether the "components" be hardware, software, or people. Consider a person who wants to send a letter. He or she addresses an envelope and puts the letter in a mailbox. It is picked up by the Postal Service, and depending on how far it must go, the letter may take several truck and plane rides and pass through several post offices before arriving at the destination.

People sending and receiving mail need not concern themselves with the inner workings of the postal system. These are unnecessary details most people don't need (or want) to know anything about, so they are hidden from view. In turn, mail clerks have no business reading the mail they handle. All the information they need to do their jobs is written on the outside of each envelope in a standard, well-defined way, and the contents of the letter are delivered unchanged. There are also envelopes inside of envelopes; for example, a batch of letters all going to San Francisco can be placed in a sack for shipment. Now the truck drivers or airline cargo handlers need not handle individual letters; they need look only at the single destination written on the outside of the sack.

Several key principles are in use here.

1. Detail hiding: Each level in the hierarchy hides the unimportant details of how it goes about its job from the levels above it.

2. Encapsulation: Each level expects that the information it passes through a lower level will emerge unchanged.

3. Procedural standardization: The procedures used for peer-peer communication (e.g., the language used by correspondents in their letters, the procedures for scheduling and tracking postal truck shipments) are agreed on by the parties involved.

4. Interface standardization: Each pair of adjacent layers must agree on the exact services to be provided and the language to be used for communication between the layers. For example, the postal services maintain lists of routing codes (zip codes in the U.S.) and standard abbreviations. It also expects to find destination addresses written on the outside of envelopes in a standard way.

Clearly, a well-organized, hierarchical structure (along with the features just listed) is vital for something as large as the postal system to function, and this is even more important in a computer network. The amateur packet-radio network has already become one of the most complex systems ever built by hams, and a clear picture of how all the pieces fit together is essential in making it all work.

Fortunately, there is much outside experience that we can draw from in designing our network. Packet switching originated in experiments begun in the late 1960s by the U.S. Defense Advanced Research Projects Agency (ARPA). These projects were so successful that by the mid-1970s companies were forming to market packet-switching services commercially. Efforts began to standardize the interface protocols between a public network and its users; this resulted in the widely used X.25 protocol.

Many similarities between the components of the networks built by different groups were seen. From the need to describe these components in a reasonably uniform way, the *International Standards Organization Reference Model for Open Systems Interconnection (ISO RM)* was devised.[4] The *ISO RM* defines a set of seven hierarchically arranged "layers," each providing functions often found in a computer network. It is very important to remember that the *ISO RM* is only a guide for describing existing computer networks. It was never intended to be a set of requirements for how they must be built, and in fact the component layers in many existing networks do not correspond exactly to those in the *ISO RM*.

The seven layers in the *ISO RM* are, from low to high: Physical, Link, Network, Transport, Session, Presentation, and Application. It is common to refer to a layer by level number, e.g., "level 1" is synonymous with the Physical layer, "level 2" with the Link layer, and so on. Since it takes a fair bit of space to properly cover the ISO model, I'll give just a brief outline here and refer the interested reader to any of the excellent descriptions that have appeared elsewhere.[5,6]

1. The Physical layer handles the electrical aspects of communication between two points. The pinouts of a connector, the modulation scheme of a modem, and the signaling rates are examples of things usually considered to be in this layer.

2. The Link layer handles the procedures for the transmission of blocks of data (often called frames) between two points in direct physical communication. It provides the means for distinguishing the beginning and end of each block of data, and usually ways to handle arbitrary data streams (transparency) as well. The link layer may or may not take special steps (such as retransmissions and acknowledgments) to improve reliability, although this is not always done.

3. The Network layer handles addressing and routing, essential facilities if a network is to have more than two stations and allow communication between stations that do not have a direct physical link (i.e., their communications have to be relayed through other stations).

4. The Transport layer is the first "end-to-end" layer; it manages network facilities on behalf of the higher layers and generally ensures the accuracy and reliability of data transfers on an end-to-end basis. It sometimes provides end-to-end "flow control," that is, it helps keep the destination (and the network) from becoming overloaded by sending data only when the destination is ready for it.

5. The Session layer is, unfortunately, somewhat vaguely defined. It is supposed to "manage" the transport facilities (although, in a sense, every layer "manages" the layer below it). It routes data between the transport protocol and the various program modules that require network services. It also provides special services that might be needed when a transport connection is established or torn down.

6. The Presentation layer loosely covers anything having to do with data formatting. Character sets (e.g., ASCII), the "escape sequences" used for special functions on CRT terminals, end-to-end encryption, and data compression are all generally thought of as Presentation layer functions.

7. The Application layer is the raison d'etre for all the other layers: It is the program which needs to communicate (presumably on behalf of a human user somewhere) with another program in a different computer system.

That the ISO model is still around is a good indication that it includes many fairly fundamental ideas, and so it is still useful in describing computer networks. But networking technology has evolved in the meantime, and so in many cases a layer whose "job" seemed well defined and necessary at the time is no longer considered very important; likewise, other layers become complex enough that many people begin to think of their tasks as really being several "sublayers."

Another view is the U.S. Department of Defense Protocol Reference Model (also known as the "ARPA Reference Model").[8] The ARPA model has only four layers (from low to high): Subnet, Internet, Host-Host, and Application. While similar in many respects to the ISO model, the fundamental concept in the ARPA model is the "internetwork" (the ARPA protocols are often referred to as the "Internet Protocols"). The Internet consists of an interconnected set of dissimilar "subnetworks," each with its own internal network protocol "underneath" the ARPA protocols in the hierarchy. This is just a generalized extension of the hierarchy concept wherein an entire network is treated as just one "link" in an even bigger "internetwork." There is only one protocol at the Internet layer, and this is naturally enough called the Internet Protocol (IP). The most important ARPA Host-Host protocols are the Transmission Control Protocol (TCP) and the User Datagram Protocol (UDP).

There is still quite a bit of similarity between these two models. They are both based on the fundamental idea of a hierarchy of functions; each has functions which are done on an end-to-end basis and others which are not. What's important in both models is the relative position of a component in the hierarchy, not the fixed "level" designation it might have. (See [7] for an amusing proof that N = N + 1 for any value of N when the relative nature of layers is ignored).

Since ARPA pioneered the (now very popular) concept of "internetting," it was not reflected in the original *ISO RM*. Therefore, the *ISO RM* has begun to sprout "sublayers," particularly at the Network layer (level 3). ARPA's Subnet layer corresponds to everything from the lower half of the ISO Network layer ("level 3A") and down, while the ARPA Internet layer corresponds to the upper half of the ISO Network layer ("level 3B"). The ARPA Host-Host layer performs the functions usually associated with ISO levels 4 and 5 (Transport and Session), while Presentation layer functions were considered application-specific enough to be merged with the ARPA Application layer.

New Developments

Now that we've reviewed the ISO and ARPA models, the fact that "AX.25 level 2" does quite a bit more than "link-layer" functions should become clear. The addressing portion of AX.25 seems to correspond most closely to the ISO Network layer, while the LAPB portion (that part which manages connections and retransmits lost packets) seems most like the Transport layer. Now that we've laid down a "divide and conquer" foundation, we can finally discuss in detail the various proposals for solving the problems we have in our current network. This is, of course, where the real fun is. In a field as fast-moving as computer networking, plenty of heated controversies arise. Some things, like the order in which the bytes of a packet header should be transmitted on a channel, are akin to deciding whether cars should be driven on the left or right side of the road. Clearly, which procedure is actually chosen is much less important than getting everybody to do it the same way!

Other issues, such as where (or if) a given function ought to be performed, are much more fundamental and reflect the different philosophies, objectives, and biases of the various designers. Some of these differences can be very deep, which is why the (often heated) discussions about them are commonly known as the Holy Protocol Wars. The mere existence of a controversy, however, usually indicates that no single approach is ideal in all situations, so it is very important to understand fully the pros and cons of each side.

As mentioned earlier, the current "packet switches" in our networks (i.e., digipeaters) are completely stateless, and this accounts for some of our problems (large packet headers, lack of hop-by-hop acknowledgments). So one question is: "How much state should be added to each packet switch to solve these problems?" To do hop-by-hop acknowledgments, for example, the switch will have to hold each packet in a buffer, retransmitting it if necessary until the next switch acknowledges it.

To eliminate the need for the user to specify the complete "source route" in each packet, the switch will need to maintain its own "routing table." Given the information carried in each packet, this table determines where the packet should be sent next. Should this routing table be based solely on destination addresses (thereby requiring the destination address to be carried in each packet), or should it also contain information about whatever end-to-end "connections" that might exist so that each packet need not carry the entire address? This is the crux of the famous "datagram vs. virtual circuit" argument. A virtual-circuit (also called "connection-oriented") network requires that each switch along the path be notified in advance of the transmission of data, so that a fixed route for the data can be set up. The CCITT protocols, such as X.25 and X.75, are generally in this class. In contrast, in a datagram ("connectionless") network, the intermediate packet switches handle each packet as a self-contained entity without regard to any end-to-end connections that might exist at a higher layer (generally at level 4, the Transport layer). The ARPA Internet Protocol is in this category.

Rather than delve more deeply into the issues (and risk cries of "foul" and "equal time" from the virtual-circuit advocates, since I'll admit to being the chief advocate of the datagram approach) I refer the interested reader to the papers published in the Fourth ARRL Computer Networking Conference.[9]

Routing and Addressing

Presently, AX.25 requires the user to specify a digipeater path to any non-local destination. Obviously it would be very desirable to automate this task, because it is at best tedious, and at worst impossible when the necessary information about a remote area isn't available. The "real" network towards which we are evolving will do this automatically, so the user will only have to give the destination address. Packet switches will determine their own routes to each destination and regularly exchange this information with other packet switches. In the worst case, each packet switch would have to maintain a complete list of every other station in the network along with the next hop to be used in reaching that station.

This is because amateur-radio callsigns (at least in the U.S.) do not give any definite indication of the station's location; a licensed amateur is free to move anywhere in the country while retaining the same callsign. This is an example of what is called "flat addressing," where addresses don't necessarily indicate anything about location within the network. Because the stations can move at will, flat addressing is clearly a great convenience to the user. The only requirement is that each address be unique, and the government already guarantees this to be true with amateur-radio callsigns.

(One clever way to allocate flat addresses in a non-amateur network without explicit central coordination is to use the serial numbers on paper money; tape a dollar bill to your computer and the government again guarantees you a unique number.) Flat addressing is just fine when everyone has a direct path to everybody else, since you don't have to keep a big routing table.

The alternative to flat addressing is hierarchical addressing, where the approximate location of each station is encoded in its address. An example of this is the telephone network; the area code locates the phone to a state or portion of a state, while the exchange generally narrows the area to a town or portion of a city. While less convenient to the user (you have to change your phone number when you move), hierarchical addressing clearly saves an enormous amount of routing table space. (With the cost of computer memory plummeting toward zero, though, it is not unthinkable that flat addressing even in the telephone network could become practical in the future.)

For the near future, however, it seems likely that some form of hierarchical addressing will be used in the new networks being designed. This means that the network will need more than just the callsign of the station you want to communicate with. Fortunately, the user need not be concerned with having to remember everyone else's network address. Special stations could be set up to provide "directory assistance" service, and this service can be checked automatically by the user's computer each time he wishes to communicate.

Transport Protocols

As mentioned earlier, there are two schools of thought on which "true" network (level 3) protocol ought to be used in amateur packet radio so that AX.25 could go back to being "just" a link-level protocol. It turns out that the internetworking protocols developed by ARPA (IP, based on datagrams) and CCITT (X.75, intended for the interconnection of Public Data Networks operated by different companies or countries, and based on interconnecting X.25 virtual circuits) are both possible bases for building an amateur network. (Consider a local rf "community" to be the subnetworks making up the amateur radio internetwork.) Both can operate on top of AX.25 level 2 as the subnetwork (local area) protocol, using it to provide the hop-by-hop acknowledgments which are generally considered necessary for performance reasons in amateur packet radio. (Other link-level protocols are also suitable for use under IP; see [10] for a detailed discussion.)

Most networks, datagram or virtual circuit, do a very good job of getting packets to their destination. No network, though, can guarantee absolute 100% reliability—just as the U.S. Postal Service can't guarantee that they'll *never* lose a letter. Recovering from these (hopefully rare) losses is the job of the Transport layer.

The Transport layer operates on an "end-to-end" basis. It detects when packets get "lost in the mail," taking action to make sure that the lost information is retransmitted. The Transport layer is relevant here because its design is heavily influenced by the services provided (or not provided) by the network.

The Transport (level 4) protocols used to provide flow control and error recovery on an end-to-end basis would be the ARPA Transmission Control Protocol (TCP) in the case of IP, or one of the simpler "X.224 Transport Classes" in the case of X.75. Here we see an example of a tradeoff in the network design: A datagram-based network has simpler packet switches than a virtual-circuit network, but requires a more complex transport protocol.

Development Status

Considerable progress has been made in the implementation of these protocols in the amateur service. At the 5th Amateur Radio Computer Networking Conference, sponsored by the ARRL at Orlando in March of 1986, the following demonstrations were given:

1. The ARPA protocols: IP (network); TCP and UDP (connection-oriented and connectionless transport protocols, respectively); Telnet, FTP, and SMTP (the presentation-layer protocols for remote login, file transfer, and mail transfer, respectively). I wrote these protocols in C and demonstrated them on a Xerox 820, although my code has also been ported to a variety of other processors. (The source code is available free of charge to anyone wanting to experiment with it for noncommercial applications; send me a blank 5.25" DSDD MS-DOS or 8" SSSD CP/M floppy with return SASE.)

2. A virtual-circuit network-level protocol based on a modified form of CCITT X.75. It was written in Z-80 assembler by Howie Goldstein N2WX and run on the TAPR TNC-2. Connections were established on an end-to-end basis, with hop-by-hop acknowledgments provided by the AX.25 link layer. Persons interested in experimenting with this software should contact Howie.

Conclusions

This is indeed an exciting time for amateur packet radio. Although this article was necessarily brief, I hope that you have gained some understanding of the considerable progress being made in the area of higher-level protocols. These developments will be an essential part of a unified network operating on a national and international scale that will be both more efficient and easier to use than the local-area networks that exist today. This will foster an even closer coupling between personal computers and radio communications. The ARRL sponsors activities to promote and coordinate the development of this technology, primarily through the Ad Hoc Committee on Digital Communications and the annual Amateur Radio Computer Networking Conferences.

The uses to which the amateur network will be put are limited only by our imaginations. The potential of this network for public service and disaster communications is clearly enormous. It will provide the opportunity for amateurs to gain inexpensive, hands-on experience with a technology very relevant to the non-amateur world. On the basis of these and other achievements, amateur packet-radio networking has done and will continue to do much to advance the Basis and Purpose of the Amateur Radio Service as stated in FCC Part 97.1.

The possibilities are limitless, so if you have an interest in contributing to this effort, by all means jump right in! One request, though: Please let the rest of us know what you're up to. Write papers and articles on your work whenever you feel you have something of interest. Some very interesting packet-radio developments have gone largely unnoticed because the people involved never thought it worth mentioning! ■

Lightning Never Strikes

Ham radio vs. Mother Nature: Can you survive? Protect your investment—and your life—with these few simple precautions.

Since my article, "Defuse RFI," appeared in the October, 1983, issue, I've been bombarded by requests for more information on lightning protection and grounding in general, so here is some simple information that covers just about any grounding situation.

When Ben Franklin invented the lightning rod, it kept the barns from burning down, but Ben went to his grave wondering why no one had ever *seen* lightning strike one, even though he had solved the problem.

The reason is very simple: A lightning rod doesn't *attract* electrical atmospheric discharges, it establishes a constant electrical *drain* which, in effect, neutralizes an area of approximately 500 square yards. Therefore, lightning will strike a tree because the tree's resistance is higher than that of the ground (which has a very low resistive value).

Living where thunderstorms are born, I've had a lot of experience in protecting homes where the owners have lost TVs, stereos, microwave ovens, and even atrium water pumps. Usually I'm the last one called: The first recourse is usually to call a TV repair shop—getting a man to come out and survey the situation and give an estimate (usually over $1000) based on a lot of wrong approaches and a lack of fundamental knowledge (which unfortunately is typical). At this point the home-owner calls a consulting engineer (me), figuring it can't cost much more, and wants a second opinion. I quote about $200 for parts and labor and come out smelling like a rose money- and reference-wise. The following is a handy "instruction manual" on how to do it simply and correctly.

The first step is to drive a 6–8-foot ground rod next to the foundation of the building, where moisture is retained by capillary action. Don't use the "saddle" clamp that comes with the ground rod since it is subject to electrolysis and will loosen all by itself—go to an auto supply store and get a stainless-steel, worm-drive, universal fuel-hose clamp about ¼" larger than the diameter of the ground rod. Don't over-tighten this clamp as it strips out at about 6 psi; so good and tight is tight enough for the ground connection (it won't loosen). Waterproof with acrylic spray, silicone seal, or nail polish.

I then use a 10-foot section of TV steel mast, a 5-foot tripod, a trailer-hitch ball, and enough #8 wire to reach from one lag screw of the tripod mount to the ground rod. According to the U.S. electrical code, the wire does not need to be insulated, but no splices are permitted. The tripod mounting should be waterproofed with roofing tar or silicone seal. The ball is welded to the top of the mast section. The final step is simply to install a GE 120-volt MOV (metal-oxide varistor) on each side of the 220-volt drop to power company ground (the bare wire) in the fuse or breaker box, *after the fuse or breakers*, so the breaker will "pop" if the varistor shorts out. Turn the breakers *off* or remove the fuses when doing this.

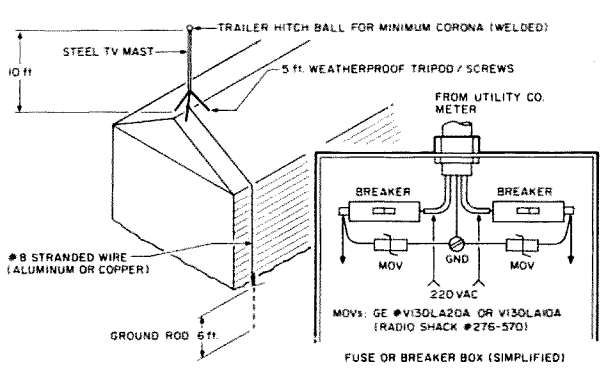

Fig. 1. Simple precautions to protect your home from lightning.

For a ham with a roof-mounted antenna, all that's necessary is to run the #8 wire from the mount to the ground rod as previously explained and add the MOVs. The coax should be broken, a PL-259 installed on each end (at the antenna mount), and a double-female coax lightning arrestor (Blitz Bug, etc.) installed at the splice and attached to the antenna mount with a stainless-steel, universal water-hose clamp (auto supply store). This must be waterproofed with high quality electrical tape (Scotch 33 or 88) or Coax-Seal putty. The same instructions apply to a tower, with the exception of an *additional* 6–8-foot ground rod installed at the tower's base. If the tower is 50 feet or less from the building, it's covered by the "drain effect" area (assuming a "non-isolated" antenna—otherwise it creates its own drain effect).

In one dramatic case, a home-owner sustained a direct hit on the utility pole and "pig" feeding his house that literally blew the pole out of the ground. After the power company crew replaced the pole and transformer, the person checked out every electrical device in the house and found he hadn't lost a light bulb! He called me and said to use him as a reference anytime (he's a pilot for United Airlines) and confessed he had had doubts as to the effectiveness of my work, but not anymore!

In summation, I well understand the nature of the human condition as to "What's in it for me?" outside of the obvious protection. Well, it's been my experience that a properly grounded station will enjoy a 1–2 S-unit improvement transmitting and receiving, a condition in itself that makes the job worth doing! ■

And If That Wasn't Enough . . .

NK6K takes questions from the audience.

Most of the articles in this issue are tutorial in nature, rather than Question and Answer. Wishing to leave no stone unturned in the quest to get you interested in packet radio, we present: Packet Q & A.

The first envelope, please:

Q: What is packet radio?
A: Come on, you can do better than that. Unless you have been actively trying to avoid hearing anything about packet, you at least know that packet is a way of sending information over radio with computer assistance. The word "packet" is even appearing in the teeny-weeny print of the "section news" in *QST*. Packet is in use by all facets of the hobby, from the purely technical side (computer nerds) to the purely communications side (traffic handlers). The box you add to your station to do packet with is called a terminal node controller (TNC).
Q: Fine, but what's in it for me?
A: Now we're getting down to it, eh? If you are interested in computer networking, amateur packet radio is the perfect outlet for your creative talents. The packet technical scene is a vast open area of work waiting to be done.

If you are not a computer experimenter, but want to be well informed about amateur radio in general, packet-based information systems are sprouting up like weeds. On the local bulletin board systems (hold that question for later) here in Los Angeles, you can find the latest AMSAT bulletins and orbit predictions; the latest ham news from the *ARRL Letter*, the *W5YI Report*, and various other sources; the text of the latest FCC notices; and, of course, news from the world of packet. Other areas carry any of several DX bulletins and propagation forecasts. International newsletters are starting to become more common as links overseas are established.

Packet can also be used to just chat with others.

Photo A. The N6BGW-9 BBS, running semi-unattended on 146.745 MHz.

Q: What is a bulletin board system?
A: As the name implies, a bulletin board system (BBS) is a place to store bulletins so that others can read them. A BBS consists of a computer that has space to store messages and files and a program that allows hams to leave and retrieve them. The messages may be of general interest (like getting a propagation forecast or asking for a loan of a wattmeter) or they may be specific (like confirming an 80-meter schedule).
Q: You sound as if packet is the only mode that has that stuff. Aren't there RTTY-based bulletin board systems?
A: Yes there are, but BBS use has become widespread with packet. The first reason is that packet is faster. On two meters, packet is running at about 1,440 wpm, as opposed to 100 wpm maximum for Baudot-RTTY. In numbers that mean something, on two meters it would take about 26 minutes to send the latest AMSAT news at 100 wpm Baudot and about 2.5 minutes using packet. It would take 52 minutes to transmit the *ARRL Letter* on RTTY and five minutes on packet. Because of this, not many people would consider putting a large newsletter on a RTTY mailbox—there wouldn't be enough time in the day for 20 or more people to read it.

The second reason is that packet shares the channel. Due to the way packet works (and you can ask that later), several people can use the same frequency at the same time. Thus, while someone is chatting about the weather, someone else can be reading a propagation forecast. Although both acts will take a little longer if the frequency is shared, at least one party isn't gritting his teeth, waiting for the seventh person that day to read the same message before he can chat.

The final reason is that packet detects any errors that occur during transmission and corrects them by "asking for fills." Thus, it now becomes possible to reliably download files where a small error can cause big problems, like files containing orbit predictions or a file listing the times when the Heard Island

DXpedition will be on 80 CW. If you get a wrong number, you'll be wondering why the band is so quiet.

Q: I get my news by listening to Bud replay the *Westlink* tape on the local repeater. Why should I invest in new gear?

A: A bulletin board system is there when you are. If you want to get your news from Bud, you have to be there when Bud is holding forth on the repeater. If you get moved to the night shift at work, there goes your news. A BBS (a non-real-time system) frees you from the clock and Bud's schedule. You can even talk to Bud on the BBS or leave him messages that he can read when he's available, and Bud can store messages for you when you're not.

Q: All this is fine, but I'm a HAM, not a news hawk. If I want news I'll watch cable. What good is packet to real hams and not computer nerds?

A: In addition to the above types of activity, packet is used by hams who simply want to chat, just as on RTTY, AMTOR, and CW.

Q: But what do you talk about?

A: Anything of mutual interest or even of unilateral interest. Packet just moves the characters; what you put in is up to you.

Q: My buddy told me packet is only one-on-one, that you can't have a round-table discussion.

A: You can have a round-table discussion on packet, either one-to-many or many-to-many. These work best when everyone can hear everyone else, either directly or through a duplex repeater. Every Monday night in the Los Angeles area, at 9 p.m. on the N6GPP repeater (146.145 in/146.745 out), a packet round table is held. One occurred last night while I was writing this.

The way it works is everyone connects up in pairs and sets the packet equipment up so that other conversations are also displayed. Everyone can now see everyone else. Because N6GPP is a digital duplex repeater (described later), any packet sent by you that is heard by your connect partner will be heard by everyone else. Any packet missed by everyone else will also have been missed by your partner, and your TNC will resend it.

In the net last night, there were 30 people checked in. In the time the major portion of the net occurred—from 9 p.m. to 11:30 p.m.—69,000 characters were sent. This is a count of characters actually typed by someone, and does not include retransmissions or callsigns. That comes out to about 460 characters per minute, or 92 wpm. That doesn't mean that there were any 92-wpm typists on the net; 30 people typing at 3 wpm would have the same effect.

Q: What do you talk about in a packet round table.

A: Anything you want. Topics discussed on last night's net included: The Stoner proposal for a Public Digital Radio Service; AMSAT's upcoming Phase-3C launch; no code, with support for and against; the number of repeaters in England; hard disk problems with a local mailbox; tightrope-walking pigs (don't ask me why); how to get more people interested in amateur radio; open versus closed repeaters on 70 cm; autopatches, good or bad; compact digital audio discs and the music on them; Captain Midnight of HBO fame; and a lot of miscellaneous background chatter.

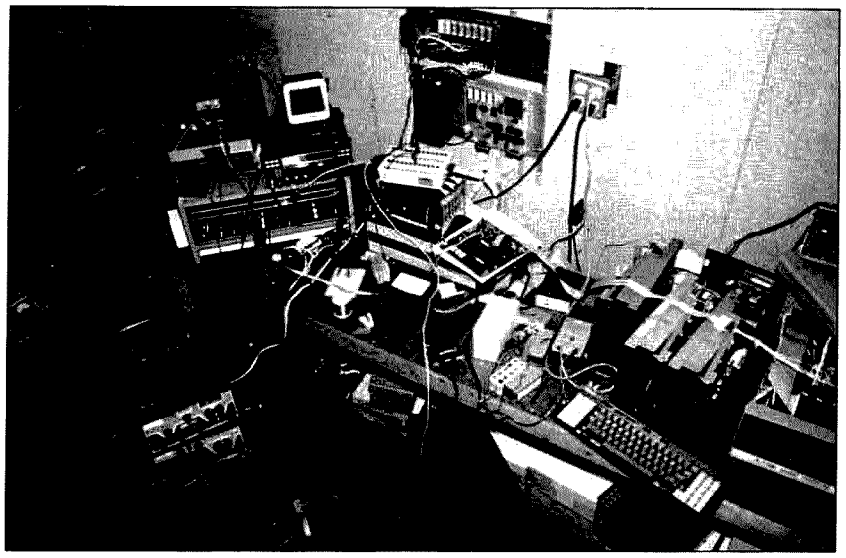

Photo B. This station is equipped for packet use on HF, VHF, UHF, and OSCAR 10. See text.

In general, you talk about the same things anyone talks about on a ham net.

Q: Real hams don't use nets. Can I call CQ?

A: Yes. You can direct your CQ into distant areas by using packet repeaters called digipeaters, and you can include text with the CQ—for example, "CQ anyone who wants to talk about fly fishing." You can also set your TNC up so that it displays only packets sent by people calling CQ. In fact, you can set up some TNCs to not display packets from certain people, so if someone is sending data you don't want to see, you don't have to see it. There is *no* truth to the rumor that TNCs come from the factory trained to ignore packets containing editorials from W2NSD/1.

Q: Speaking of callsigns with "/" characters in them, my TNC won't let me use my full call, G4JPZ/W6. Why not?

A: The number of characters devoted to storing the callsign of packet stations was a Big Issue in ye olden days. The call is sent in every packet, and the fewer characters of overhead, the better. The number agreed on was six, as this would contain all the characters needed to uniquely identify a station using the call assigned by its home government.

Q: What does the number in packet callsigns like WB6YMH-2 mean?

A: Each TNC must have a unique identifier. Because a ham can own more than one TNC, just as he can own more than one radio, it is necessary to have a way to distinguish the various TNCs owned by WB6YMH. The number, called a secondary station identifier (SSID), is used for that purpose. SSIDs run from 0 to 15; 0 is assumed if no number is stated. There have been various schemes purposed to "band plan" the numbers—e.g., 0 is your personal station, 1 is your first digipeater, 7 is your satellite gateway, etc.—but none of them have yet caught on. There are too many types of stations and not enough numbers.

Q: Is packet used for public service?

A: I'll give you an example. Pittsburgh, Pennsylvania, recently had a marathon, and as usual hams supplied public-service communications. Packet was used to move information on downed runners from out on the course to the finish line, where family and friends waited. A packet base station was set up at the end of the course, consisting of a Compaq computer running a data-capture program, a TNC-1, and a printer. A battery-powered mobile packet station was placed in a truck that drove along the course. This station, made up of a Data General 1 laptop computer and a TNC-2, stopped at 15 aid stations, gathering names and dispositions for relay to the finish line. The names were typed on a keyboard only once; after they were transferred via packet to the base station, they were printed by the computer and posted in the reunion area. Two digipeaters were used at different points along the 26-mile course: W3VC and WA3YOA-3. N3CVL and W3MC ran the base station; WA3HGW was in the truck.

Q: I hear a lot of different names for repeaters in the packet world. Why are there so many kinds, and what's wrong with using just a regular repeater?

A: The major types of repeaters you'll hear about are voice repeater, digipeater, dual-port digipeater, and digital duplex repeater. We'll take them one at a time.

The term **voice repeater** refers to the traditional repeater commonly found in the two-meter band. In most such repeaters, the audio output from a receiver is passed more or less directly to the audio input of a transmitter. Any FM signal heard by the receiver is sent out of the transmitter. It is therefore possible to send packets through a "voice" repeater. It is inadvisable to do so, however, on any repeater in which the user support communi-

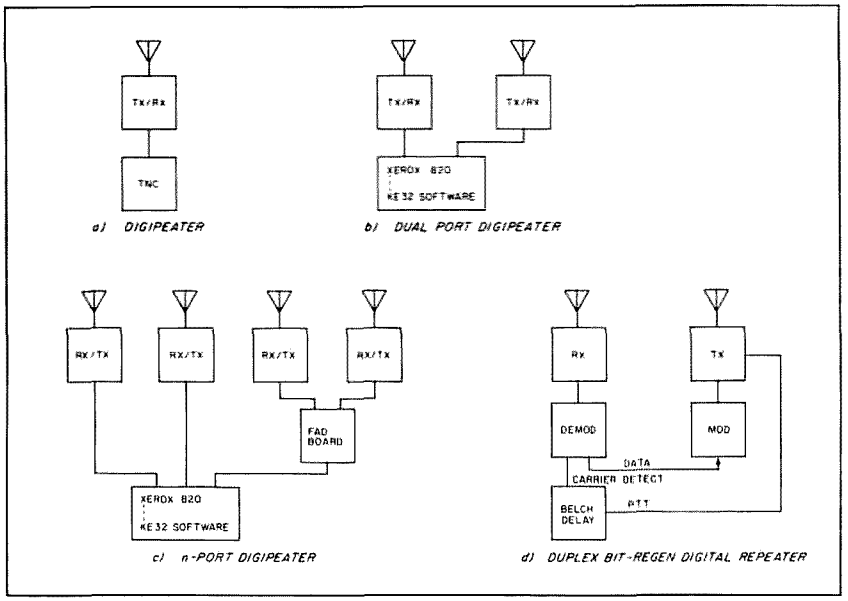

Fig. 1. Packet repeater configurations.

ty is not interested in such activity. Nothing is more certain to bring the villagers up the winding path to your castle's digital laboratory with torches and flaming pitch than pumping "braaaaap" through the local voice repeater during the nightly bull session.

By "user support community," I mean those individuals who make up the repeater group and support the repeater with time, talent, or other resources to keep it running. Cretins who think the repeater is a public utility can be ignored as always. There are plenty of other frequencies around, so stay away from the "No Digital" voice repeaters, and we'll hope they stay away from the 145.0 through 145.1 digital area. Fortunately, only a few of the misguided individuals in the "My license says I can transmit anywhere Part 97 says I can" group have found their way into packet.

A **digipeater** is a digital-only device. As shown in Fig. 1(a), it is the simplest of all packet devices, consisting of a TNC and a transceiver. A terminal is used initially to set the TNC's parameters, but it is not required for operation. A digipeater is a simplex repeater. It listens for packets on a frequency, checks them for accuracy, and then retransmits them on the same frequency. Any packet station can serve as a digipeater. Stations intended for remote or mountaintop service are usually "hardened" (see "Survival Training For Mountaintop Digipeaters" in this issue).

Fig. 2. The mail-forwarding network in action. D) The original message sent on Uo-11. C) That message as sent eastward from Los Angeles. B) The message as it arrived in Washington DC. Each BBS that forwarded it has placed an ID stamp in the message. A) The received message as sent to Los Angeles again on Uo-11.

Digipeaters can be "linked" in chains of two or more on a packet-by-packet basis. The callsigns of digipeaters can be placed in a packet along with the source and destination stations. Each digipeater repeats the packet in turn, which can send the packet hundreds of miles. Although this scheme does have its limits, digipeating allows simple linking without requiring multiple radios and antennas at the digipeater site.

A **dual-port digipeater**, shown in Fig. 1(b), is a more complex version of the standard digipeater. It was first developed by Jon Bloom KE3Z and others at the ARRL lab in Newington, Connecticut. A dual-port digipeater can digipeat packets on two radios at the same time. Although this is more complex in terms of rf, the advantage is that two frequencies can easily be linked together. Packets received on one frequency can be repeated on the same frequency or on another one by the other radio. Which frequency is used is controlled by tables in the digipeater's software. Aside from linking packet communities on two frequencies, the dual-port digipeater can be used to move packets off of a heavily used local frequency and onto a "backbone" frequency.

For example, suppose that most of the packet users on the East Coast were on 145.01 MHz. If you try to use a string of four standard digipeaters on 145.01 to connect to someone 300 miles away, you would have to contend with all the other users of 145.01 throughout the 300-mile range. Obviously, if 50 people are trying to share a single frequency equally, the most you'll get for yourself is 1/50, which isn't much. Now let's assume that there is a dual-port digipeater at both ends of the chain, one where you are and one 300 miles away. You transmit your packet on 145.01, and it is retransmitted on a second frequency, perhaps 220.95 MHz. Your packet could then go down a string of standard digipeaters on 220.95 until it gets to the end, where it would be repeated back onto 145.01. The advantage is that you've bypassed all the local traffic on 145.01 between the two ends. A "backbone" is just like an interstate highway. If access is limited to occasional on-ramps, it can be used to bypass business districts.

An **n-port digipeater** is just a bigger dual-port digipeater. As shown in Fig. 1(c), you can add as many ports (places to stick radios) as the hardware will bear. The original dual-port code was first implemented on a Xerox 820, which had two ports. A device called a FAD board, designed by the FADCA group in Florida and available from TAPR, extended that capability to four ports. Contact KE3Z at the ARRL if you want a copy of the software.

A **digital duplex repeater** is much like a voice repeater except that bits are passed between the receiver and transmitter rather than audio. Fig. 1(d) shows such a device. Audio from the receiver is passed to a demodulator. Data from the demodulator is passed first to a modulator and then to the transmitter, which is transmitting on a frequency other than the receive frequency.

Photo C. Is I/O The Dog (NK6K-4) burying the CW key...

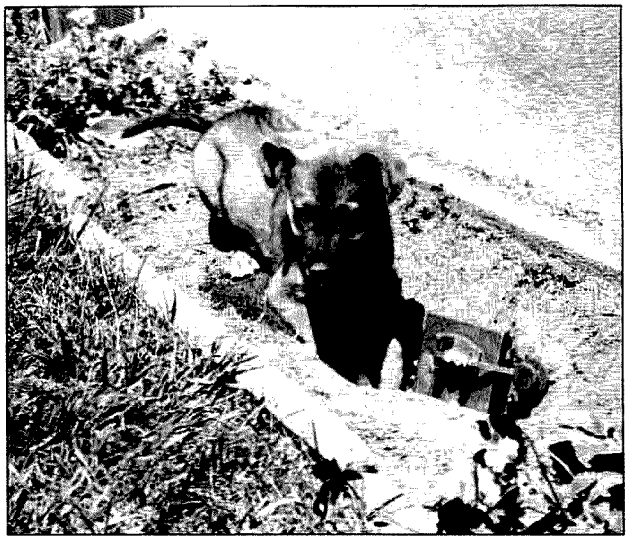

Photo D.... or is he resurrecting it?

The advantage of this over an audio repeater is that each bit starts fresh at the transmitter. The output audio can be more closely controlled. The advantage over a digipeater is speed; the packet is retransmitted as it is received, rather than being repeated after it has been completely received and checked. Another advantage is that, except in fringe areas, each station listening to the output of the repeater will hear exactly what every other station is hearing. If one station correctly received a packet, chances are good that all other stations in range of the repeater heard it as well. This makes packet round-table sessions much easier to hold.

The disadvantage over digipeaters is that a duplex repeater will retransmit a damaged packet (one that is weak at the receiver or that has suffered a packet collision) when two packets from different stations start at the same time. Duplex repeaters cannot be linked as simply as simplex repeaters, since a second pair of frequencies must be used. The N6GPP digital duplex repeater in southern California avoids this problem by being a hybrid. It is also a dual-port digipeater; one port is connected to a simplex frequency, the other to the duplex repeater. Packets received via the duplex input can be digipeated out on the third frequency and vice versa.

Q: I also hear about things like bulletin boards, mailboxes, file servers, and hosts. Are they the same or different?

A: These names all refer to basically the same thing: a computer attached to a TNC, performing a central service for other packet users. They all look the same at the hardware level; each is a personal computer and has a certain amount of disk space. The different names specify the type of service offered by the system. The names are not standardized, and there is some overlap.

A **mailbox** implies that only a mail storage service is provided. Messages, usually limited in length by software or convention, can be stored. They can be addressed to individuals or groups. A facility usually exists to retrieve messages based on whom they are sent to or who sent them. Each message has a title tagged to it, which can be displayed as a quick summary of the contents of the mailbox.

A **file server** stores only files. The files can contain messages, but a file server does not have fancy retrieval methods. Files are stored by name and retrieved by name; they do not have addresses. Files can be any size, and usually contain long reports, newsletters, digipeater maps, etc.

A bulletin board system is a combination of a mailbox and a file server. It has a mailbox facility as well as a place to store large files. This is the most common system found. Messages can be placed in the mailbox that describe the contents of files placed in the file area.

A **host** system is potentially the most powerful system of all. In all of the above systems, a program is running that "talks" to the user and provides the various services. In a host system, the user is talking directly to the computer's operating system, just as if he were at the local keyboard. He can run a variety of programs, including a mailbox program if one is available. One common program found on amateur packet hosts is a satellite orbit prediction program for tracking OSCAR satellites. Games are also common. Any computer can be used; I have seen both UNIX and CP/M systems running on packet.

There are many different software packages available to implement all of the above types of network service packet stations on almost any computer. All of them have been written by hams or adapted from other sources by hams. Software exists for Commodore 64, Apple, generic CP/M, generic MS-DOS, TRS-80 (all models including the 100), UNIX, and at least one Data General Mini. The quickest way to get on the trail of this software is to leave a message to the sysop of your local BBS. Another good place is "So You Want To Be A Sysop" in this issue. Several photos of packet BBS systems are scattered throughout this issue as well.

Q: Is unattended operation of packet stations legal?

A: Yes. The FCC recently issued a Report and Order on PR docket 85-105 which made several changes to the rules explicitly permitting such operation. One example:

Section 97.69 on digital communications is amended by adding a new paragraph (d), as follows: An amateur station may be under automatic control when transmitting digital communications on frequencies 50 MHz and above.

Other sections were added defining automatic control, and requiring that devices and procedures be used to ensure compliance with the rules. A controversial section that did not permit automatic control while transmitting third-party traffic was temporarily waived, pending review. The point of contention is too complex to treat well here, but basically has to do with the traditional definition of third party as communications that do not occur on behalf of the control operator. Since most of the traffic flowing on the path between Boston and New York has little to do with the control operator of a digipeater on that path, that digipeater would not have been permitted to run unattended. The packet world prefers to see third-party traffic defined as communications where one of the parties is not an amateur. Traffic originated by amateurs and destined for amateurs would not be third party, and would be permitted in all cases.

The other point packeteers made with the FCC on this topic was that once "real" third-party traffic (i.e., from a non-ham) was entered by a ham into the network, it need not be considered third party while in the network. The amateur who started it on its way has already made sure it complies with the rules. As I said above, the no-third-party provision was waived, pending review. The FCC asked that packet stations be vigilant, and be on the lookout for abuses and non-amateur use of the network.

Photo A shows a mailbox system running in the unattended mode. Hefner fans, can you spot the Bunny?

A final comment. The term "automatic control" as used in the FCC rules means that the station is unattended. When packet people talk about an automated station, it sometimes means that the actual mechanics of message relaying is automatic and that an operator is still present and is "at the control point." Thus, if you hear someone talking about automatic relay of messages on an HF station (below 50 MHz), it isn't necessarily illegal, so long as someone is actually at the control point. Unattended operation of an HF transmitter, automatically relaying messages or not, is not permitted under the current rules.

Q: All of the pictures of ham shacks in this issue look staged. Everything is too clean.

A: Well, maybe folks did clean up a bit before the photos were taken. Therefore, in the interest of truth in advertising, we present Photo B. This is from the old days of packet, when bearded experimenters toiled in basements (East Coast) or garages (West Coast), and nothing was in cabinets. To see if you qualify as a packet pioneer, try to spot the TNCs in this picture. There are two of them in clear view. This shack belongs to WA6JPR, who started up packet in the Los Angeles area back in 1981. The photo is from late 1983.

Q: I've heard both good and bad things about packet on the HF bands: stories about automatic cross-country message forwarding with coast-to-coast relay 24 hours a day, and also that HF packet is "unusable." Who's telling the truth?

A: Both have elements of truth.

Fig. 2 shows the amateur packet network in full swing, and is a look at things to come. It shows a message that was sent from the East Coast to the West Coast on the UoSAT-OSCAR-11 (Uo-11) satellite's digital mailbox, then was sent back to the East Coast using the forwarding BBS network, and then sent back to the West Coast using Uo-11 again.

The Uo-11 system is briefly described in "Birds 'N' Bauds" in this issue; forwarding BBS systems are mentioned in "So You Want To Be A Sysop." In the forwarding BBS system, the message is automatically passed from one mailbox to another, using direct VHF paths, strings of digipeaters, or HF. Each system adds a line to the front of the message when it is passed on. Although one of the systems has its clock set wrong, and some use UTC while others use local time, you can see how long the message took as it passed from place to place.

The path the message takes is not necessarily fixed; HF propagation and VHF equipment outages affect the path from hour to hour and day to day. Each system tries to pass the message closer to its destination using the best path available.

Today, this system can take longer than the human-directed CW/phone NTS system to deliver a message. On the other hand, the NTS system is more labor intensive, requiring humans to copy the messages by hand. As the packet network gets "smarter," messages will travel through the most optimum path. The NTS system is already taking advantage of packet systems in those situations where they offer the best or additional service. Traditional NTS networks are used where they offer the best service.

But we've moved away from the question slightly. The above discussion shows that the packet network is functioning. But is HF packet the panacea that some claim it to be?

Packet offers "perfect copy," where perfect is 99.999% plus a harder-to-quantify number of more nines to the right of the decimal point. (See the June NK6K > Packet column for a further discussion.) Packet does this by repeating a packet until it is received perfectly. The problem is that on a noisy HF channel, perfect can be a long time coming. Take a look at the following line of text as it might be received by an RTTY station on a noisy 20-meter frequency:

THE QICK BR WN FOXSJUMQS OVE
?FD. DOGS BACK

A human operator can make a pretty good guess that it was transmitted as "THE QUICK BROWN FOX JUMPED OVER THE LAZY DOGS BACK." Even though the message was only 69% correct, the information was passed. On packet, the message would have been rejected, and no information would have been passed. Score one for RTTY.

Now let's look at the following line of text, received by an HF RTTY BBS system:

TYPE ORBITS144

Can you tell that this was sent as "TYPE ORBITS134"? No, and neither can the BBS system, which proceeds to send you 15 minutes of last week's orbital elements. The packet system 20 kHz up the band took three tries to get the line through, but now it's reading this week's elements. Score one for packet.

We're off the path again. The question was "Is HF packet really usable?" It comes down to two things: hardware and user training. The RTTY community has spent many years perfecting terminal units (TUs) that can reach down into the noise and pull out signals. The packet community, flushed with the success of the "cheap and easy" Bell 202 modems used on two-meter FM, started out in HF using another "cheap and easy" source of modems, the Bell 103 standard.

This standard grew in packetdom for the same reason the Bell 202 standard did. The first person who promoted HF packet had a ready supply of Bell 103 modems, and he made some available to friends. Thus, first HF users were on a 200-Hz shift, and each new user after that used the same standard. The simple modems on the kit TNCs and the later TNCs based on them were retuned for 200 Hz and pressed into HF service. The reduced-parts-count TNCs used a telephone modem chip with the same standard and, presto, an HF modem. All of these modems are less than optimum and miss some bits. Any time a packet must be repeated, the frequency becomes more crowded. More crowding leads to more bad packets and to more crowding.

A close look at the modems on TAPR-style TNCs was done over the last winter to try to improve HF performance. The changes published give an improvement, primarily a reduced requirement for precise tuning. More importantly, some manufacturers are addressing the problem by making real HF modems available that are designed like HF TUs and not like telephone modems, for example the AEA PM-1. Hams are also beginning to modify RTTY TUs and use them for packet. You can either buy a $1,000 linear amplifier for your station or a $150 modem for the station you're trying to talk to. As more serious HF users upgrade their modem capability, you'll notice that your station seems to get out better.

I also mentioned user training as a factor in HF viability. There are upwards of 70 parameters on a TNC. As shipped, most of the defaults are correct for VHF use. Many are dead wrong for HF use. The parameters that will have the most effect are the packet length and the retry timer (FRACK). Experiment with these values for the best performance on HF.

One final thought on this facet of HF operating. There are many forwarding BBS systems present on HF. Most of them are on 14.107 MHz. These systems pass cross-country traffic funneled through from the larger number of VHF BBS systems and thereby benefit a large number of hams. If you connect to these systems on 14.107 or carry on a non-BBS QSO on that frequency, the forwarding systems can't forward. These stations must congregate on a single channel to forward the mail, but individuals are free to roam. Please do so. If you have another way to access the national forwarding system, like a local VHF BBS, please use it instead. If you do see an interesting DX station working a BBS to get news he can't get another way, once you contact him move off to another frequency. If this sounds like the concept of a calling frequency, it is. The more things change, the more they stay the same.

Q: How is DX on packet?

A: I knew you'd ask that, so I forwarded some messages to various VHF and HF BBS stations asking for DX information. In less than a week I received four responses back through the forwarding system. Complied from lists supplied by W0RLI, WD4BIW, W9ZRX, and N1DL, and a letter to WB9FLW from DU1POL, here is a list of countries with known HF packet activity: 5H3, 5V, 9K2, 9M, CN8, DL, DU, EA, F, G, GW, HB, HK, I, JA, KH6, KL7, KP4, LA, OH, ON, OX, PA, PJ, PY, SM, TI, VE, VK, W, XE, YB, ZF1, ZL, ZS.

There are probably more reports on the way, and there are new countries coming online every month.

Q: Will CW be replaced by packet, never to be heard from again?

A: Of course not. On the other hand, see Photos C and D.

Class dismissed. ■

On The Shelf

Most amateur packet bibliographies I've seen recently are endless lists of books and articles. In this one, I'll mention only a few, but I'll tell you why you might want to take the trouble to look them up. Most of these references contain bibliographies of their own, so you should have no lack of sources with a little effort.

Introductory Material

H. Price, "What's All This Racket About Packet," *QST*, July, 1985.

H. Price, "Packet Radio—A Closer Look," *QST*, August, 1985.

These are basic introductions to packet articles. The second article uses the TNC-2 to describe what's in a TNC.

J. Grubbs, *Get *** CONNECTED to Packet Radio*, Qsky, 1986.

This is the first book published that addresses the operational aspects of amateur packet radio as practiced in 1985-1986. It takes you from picking out a TNC up through your first connect and briefly touches on many other topics. This is the first of what will be an avalanche of "how to use it" rather than "how it works" books. This is certainly a niche that needs to be filled. While intending to keep the material basic, the author includes an extensive list of references for further study if a topic catches your fancy. A list of packet organizations and equipment suppliers is also included.

Several other slightly more technical introductory articles have been written. They are a bit dated now as most of them refer to the TNC-1-style TNC, but much of the information is still valid. They are:

M. Morrison, D. Morrison, and L. Johnson, "Amateur Packet Radio Part 1 and Part 2," *Ham Radio*, July and August, 1983.

L. Johnson, "Join the Packet Radio Revolution Parts 1, 2, and 3," *73*, September, 1983; October, 1983; January, 1984.

And one piece from the history section:

D. Borden and P. Rinaldo, "The Making of an Amateur Packet-Radio Network," *QST*, October, 1981.

This was my and many other's first exposure to coordinated amateur packet activity. In 1981, many groups were working on digital experimentation, but not all groups knew about each other. I can remember the first time I read it, lying in bed after midnight leafing through that month's *QST*. I also remember very clearly thinking that amateurs would never agree on a standard to the level necessary to build a North American network. This article is interesting now mainly for its historical value, and it includes a list of other articles of historical interest.

Technical

A. Tanenbaum, *Computer Networks*, Prentice-Hall, 1981.

You used to be able to tell the true amateur packet pioneers because they had a copy of this textbook on their shelves. It was almost required reading back in the pre-boom days, and you found out about it through word of mouth. TAPR included it in the bibliography in the manual for the TNC-1, and its fame in amateur circles grew. Back then you had to special-order one or live near a university book store. Last month I came across a stack of them in a local ham radio store. This is a real textbook; I paid $30 for mine. It gives a very readable overview of the field of computer networking. If you want an understanding of the basic technical issues of packet radio and where our network fits into the world of networks in general, buy or borrow a copy of this book.

The 1986 ARRL *Handbook*.

The *Handbook* underwent a major upgrade in 1985, and 1986 adds even more pages on digital topics. If you've been buying a handbook every 15 years or so, which used to be often enough, break your cycle and buy one this year. I can't say enough good things about it, even about the non-digital sections.

Packet radio is discussed on pages 19-23 to 19-50, and various related topics are scattered around the book.

Terry L. Fox, *AX.25 Amateur Packet-Radio Link-Layer Protocol*, ARRL, 1984.

This is a must read for people who want to write their own AX.25 code, or who want to know how AX.25 really works. AX.25 represents the most exacting set of specifications amateurs have ever lived by, at least until the networking protocols are agreed on. This book documents the outcome of various mandates, agreements, negotiated settlements, and faits accomplis that make up any protocol. It is written in standard protocolese, which makes for dry reading. This book is not for the weak of heart, and it won't tell you how to operate a packet station.

The ARRL Amateur Radio Computer Networking Conferences

The development of packet radio is the best documented effort in amateur radio history. The most obvious reason is that nearly all of the correspondence between developers was done using computers and electronic mail. These are easy to save and easy to expand into a technical paper. The papers are then easy to print and publish. The ARRL has sponsored, along with various technical groups, a series of computer networking conferences. In addition to serving as a common meeting place for in-person talks, it is also a good deadline to work against for getting your thoughts down in writing and getting them in the public eye. There have been five such conferences since 1981, the most recent one in Orlando in March, 1986. The papers presented there are published, with no editing, by the ARRL. Conferences 1–4 are now available in a single volume; the 5th conference is available separately. Along with volumes 1–4, you get all of the issues of the *Gateway* newsletter from August, 1984 through September, 1985, which document a lot of packet doings on their own.

Altogether, there are more than 600 pages of information, more than 100 articles, and 40 authors. Read these, and come to the 6th conference, which will probably be held on the West Coast. One warning: Not all of the implementation plans you'll read here ever made it past the paper stage.

Amateur Packet Radio in Non-Ham Publications

I include this section because I'm concerned about the long-term viability of the Amateur Radio Service in view of the frightening statistics that the average age of a ham is increasing one year per year, and that 0% of the respondents to the Fun! poll this year were in the 16–21 year age bracket. Packet radio is one of the more interesting things we can use as a hook to get new people into the service. Here are some non-ham publications where amateur packet has appeared. It may be easier to get a friend to read a copy of *Byte* than it would be to start him out with a magazine whose cover features an older gentleman in a suit and tee-shirt talking into a small box. At least initially anyway.

P. Karn, H. Price, and R. Diersing, "Packet Radio in the Amateur Service," *IEEE Journal on Selected Areas in Communications*, May, 1985.

J. Markoff, "Bulletin Boards in Space," *Byte*, May, 1984.

J. Markoff, "Satellite Promises Low-Cost Communications," *Infoworld*, January 23, 1984.

H. Price, "PACSAT," *Personal Communications*, September, 1985.

G. Zorpette, "The High-Tech Hobbyhorse," *IEEE Spectrum*, May, 1985.■

Kit Corner: The DSE 500-MHz Frequency/Period Counter

Looking for an inexpensive 500-MHz frequency counter? If you're willing to spend a few hours with a soldering iron, you can put together the Dick Smith Electronics kit #K-3439 for about $90. Accuracy is on the order of ±50 Hz for most measurements, which is close enough for almost every application.

The unit is built around a single-chip frequency counter, the 7216B, which includes an oscillator, data counters, and display decoders and multiplexers. The basic instrument will measure frequencies up to 50 MHz; an optional prescaler kit (#K-3432, $23) extends the range to 500 MHz.

In addition to measuring frequency, the unit also can be set up to display the period of a signal for between one and one thousand input cycles. This method is a bit more precise (though not more accurate) than the standard frequency-display mode.

Appearance

The plastic front panel is silk-screened and pre-cut. Insulated BNC connectors are provided for the input jacks. Seven large, easy-to-read LEDs make up the display, which sits behind a red plastic filter.

The case is a plastic four-piece affair, and that has been designed to accommodate a wide variety of circuit boards. There are about thirty mounting posts in the bottom of the case; you only need four of them. The rest must be cut away or ground down, which I thought was a bit of a nuisance. It took me about three passes with a grinder to get the board to sit properly.

Construction

Warning: This is *not* a hold-you-by-the-hand kind of kit! If you are spoiled by Heathkit-style manuals which advise you to "place R20 (red-black-brown) in position C after carefully bending the leads," you will be catatonic after reading, "Now mount the resistors and capacitors." I found that grabbing parts out of a giant pile and matching them to the schematic was really fun! It made me feel like I was really building something, rather than just mimicking someone else.

There were a few snags. The worst was caused by the parts-placement diagram in the manual—the parts were there, but the circuit pattern under them was missing. Most of the time it was easy to guess where a part went, but in several instances I had to put the board behind the diagram and hold it up to the light. Also, the instructions for wiring the ac transformer are a bit vague, and I had to resort to tracing leads on the PC board to decide where the wires from the secondary were to go.

Take care to read *all* of the notes that surround the placement diagram—I didn't, and ended up unsoldering a few parts that I'd put in the wrong places.

I was disappointed to find that no sockets were provided for the ICs. The manual states that "sockets may be purchased." This is inexcusable—I can't believe that three or four sockets would raise the price of the kit more than a dollar or two. It just doesn't make any sense not to socket ICs.

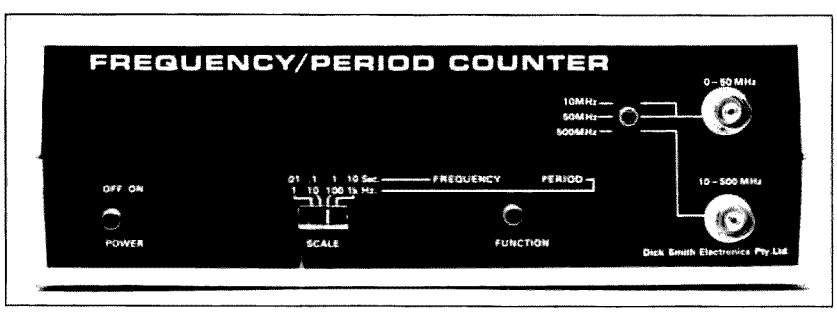

Photo A. DSE's inexpensive frequency/period counter.

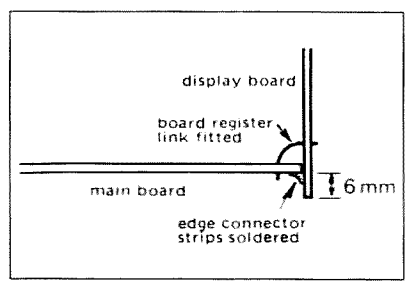

Fig. 1. You're instructed to join two circuit boards with solder fillets.

Another disappointment was the method used to mount the display. The frequency counter uses a main board for the counter and input circuitry, and a display board which holds the LEDs and switches. All of the wiring to the LEDs and switches is accomplished with PC traces; the traces on the main board mate with those on the display board. This is great for cutting down on the number of connections, but to join the two boards, the instructions ask you to use solder fillets (Fig. 1.) This may work if the boards fit perfectly together, but in my kit there was a gap of about 1/4" to fill!

At first I thought, "Well, they must know what they are doing," and I actually attempted to hook the boards together with solder bridges. I ended up ripping two solder pads completely off of the board.

I finally gathered a few dozen of the resistor leads that were scattered about my desk and formed them into connecting fingers. This worked really well; the leads were flexible enough to let me bend them around to get the boards to fit into the case. And I didn't have to worry about solder bridges forming the only electrical connection to the display board.

Apart from the problems I've already mentioned, I thought that the construction manual was fairly well done. Quite a bit of space is devoted to explaining the circuit in minute detail. Unfortunately, the manual was intended for an Australian audience, so you have to put up with power cords having blue, green, and brown wires, and with color-burst oscillators running at 4.433619 MHz. The wording in some cases is difficult to understand, but a careful re-read will clear things up in most instances.

Operation

With the counter tucked neatly into its case, I switched on the power and was pleasantly surprised not to see wisps of smoke. I don't have a signal generator, so I checked the clocks in all of my computers, the output of all of my rigs, and so on. An oscillator I built around a TV color-burst crystal was off only a Hertz or so; that made me feel pretty comfortable about the accuracy of the counter.

Obviously, this is not a lab-standard frequency counter, but then you're not paying lab-standard prices, either. I've found that the accuracy and precision of the unit is sufficient for 99% of the applications around the shack—most of the time I just want to know whether a circuit is oscillating or not. I do suggest that you spend the extra few dollars for the 500-MHz prescaler, especially if you have VHF/UHF gear.

I encountered minor frustrations while building this kit, but none of the problems were insurmountable. The unit works great, and I think you'll not find a 500-MHz frequency counter at a better price.

For more information, please contact Dick Smith Electronics, PO Box 8021, Redwood City CA 94063; (800)-332-5373. ■

PACKET
CONNECT-ALARM
for the TNC-2 and clones

Are you out of the room when another station is trying to connect to you? A LOUD BEEP FROM THE CONNECT ALARM LETS YOU KNOW WHEN SOMEONE IS TRYING TO REACH YOU. Works with the TAPR TNC-2, PAC-COM TNC-2, and A E A PK-80. The beep time is screwdriver adjustable from a fraction of a second all the way to a long 9 seconds. Fits entirely inside the TNC-2 chassis. Easy four wire hookup to TNC-2 board. Furnished with top quality I C. cermet sealed trimpot, piezo buzzer and a 1 5 inch square glass-epoxy board.

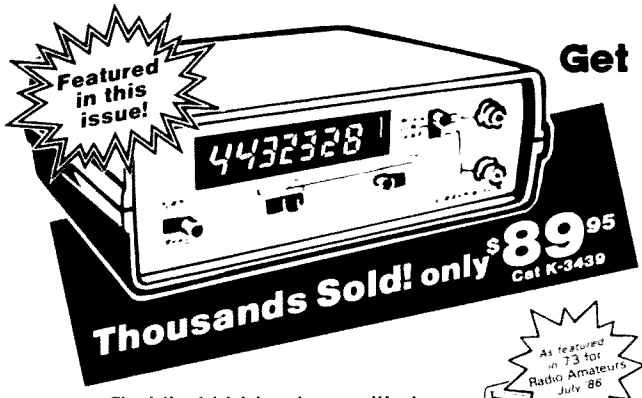
SYNTHESIZED SIGNAL GENERATOR



MADE IN USA

MODEL SG-100F $429.95 delivered

• Covers 100 MHz to 199.999 MHz in 1 kHz steps with thumbwheel dial • Accuracy +/- 1 part per 10 million at all frequencies • Internal FM adjustable from 0 to 100 kHz at a 1 kHz rate • External FM input accepts tones or voice • Spurs and noise at least 60 dB below carrier • Output adjustable from 5-500 mV at 50 Ohms • Operates on 12 Vdc @ ½ Amp • Available for immediate delivery • $429.95 delivered • Add-on accessories available to extend freq range, add infinite resolution, AM, and a precision 120 dB attenuator • Call or write for details • Phone in your order as fast COD shipment. ~79

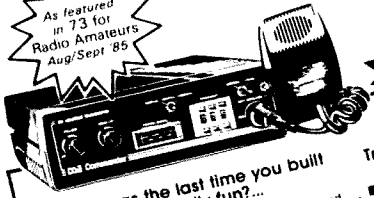
"The DSE kit packs more features than some counters costing three or more times as much." *J.Daniel Gifford in Dec '85 Modern Electronics*

Superb design featuring the latest IC technology makes this kit easy to build and reliable to use. Measures up to 50 MHz in two ranges (or higher with the prescaler kit below!). Features 4 gating periods from 0.01 to 10 seconds, 7 segment display, 4 period measuring ranges, high input sensitivity, accuracy typically better than .005%, 110V operation. What more could you ask for? DSE has it all!



DSE Digital Frequency/Period Counter Kit

DSE Prescaler Kit
A mate to the Frequency Counter Kit, this valuable add-on fits the existing PC board and extends the counter's range for professional operation at 10-500 MHz.
$22.50 Cat K-3432

Find that hidden transmitter!
●50-500 MHz range ● 170° calibration ● 12V
● Internal alignment reference ● Stable digital circuitry
● Self-aligning commutating filters

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial offices, 73 Magazine, WGE Center, Peterborough, NH 03458-1194.

COAST GUARD FESTIVAL
JUL 30–AUG 3

The North Ottawa ARC will operate KA8USK aboard the U.S. Coast Guard Cutter *Macinaw* July 30–August 3 from 1700–0100 UTC as part of the Grand Haven Coast Guard Festival. Suggested frequencies: SSB—3.875, 7.265, 14.250; CW—7.050, 7.110, 14.050. For a commemorative certificate, send QSL and a 9 x 12 SASE to NOARC, Box 44, Ferrysburg MI 49404.

JACKSON HOLE WY
AUG 1–3

The ARRL Rocky Mountain Division Convention and the 54th annual Wyoming, Idaho, Montana, and Utah Hamfest will be held August 1–3 at the Virginian Motel. For special room rates, call the motel and mention "Hamfest." The A1 campground is next to the motel for first-come, first-served basis. For more information, contact George Siegel, 130 E. 17th Street, Idaho Falls ID 83401; (208)-523-7433.

OHIO STATE FAIR
AUG 1–17

The Columbus ARA will be operating special-event station W8TO on August 1–17 to promote the Ohio State Fair. Operation will be on 80 through 10 meters. Times and frequencies to be determined by persons manning the booth at the fair (11 a.m. to 9 p.m. EDT daily). A valid exchange includes name, QTH, and RST. For a commemorative certificate, send a log extract or QSL card and an SASE to W8TO, Attn: State Fair Event Coordinator, 280 East Broad Street, Columbus OH 43215.

PRO-FOOTBALL WEEKEND
AUG 2–3

The Canton ARC will operate special-event station W8AL to celebrate the Pro-Football Hall of Fame's Greatest Weekend on August 2–3, from 1700 to 2200 UTC each day. Operating frequencies will be: SSB—14.270 and 7.270; CW—14.060 and 7.060. For a special H.O.F. QSL card, send your card with an SASE to Randy Phelps KD8JN, 1226 Delverne Ave. SW, Canton OH 44710.

AVIATION EXHIBITION
AUG 2–3

The Fox Cities ARC will operate station W9KKK August 2–3 from 1300–2200 UTC in conjunction with the 34th annual EAA International Fly-in Convention and Sports Aviation Exhibition in Oshkosh, Wisconsin. Suggested frequencies: 3.875, 7.250, 14.250. Send QSL and SASE to Dick Roll W9TA, 933 Melissa Street, Menasha WI 54952.

MT. DAVIS EXPEDITION
AUG 2–3

The Somerset County ARC will begin an expedition to Mt. Davis, the highest point in Pennsylvania, on August 2. Station AK3J will operate from 12 noon on August 2 to 12 noon on August 3 (EDT) in the lower 100 kHz of the General-class phone frequencies on 20, 40, and 80 meters; 10 and 15 meters depending on propagation; and 2m SSB. For an 8-1/2 x 11 certificate, send a QSL and large SASE to SCARC—Mt. Davis, RD#5, Box 223A, Somerset PA 15501.

VALPARAISO IN
AUG 3

The Porter County ARC will hold its hamfest on August 3, beginning at 8 a.m., at the 49'er Drive-In Theatre on State Road 49 in Valparaiso, Indiana. Admission is $3. Talk-in on 147.96/.36 and .52 simplex. For more information, write to PCARC, PO Box 1782, Valparaiso IN 46383.

ANGOLA IN
AUG 3

The Steuben County RA will present its 28th annual FM Picnic and Hamfest at Crooked Lake, Angola, Indiana, on August 3. Two miles north of Angola, I-69 to Crooked Lake Exit. Admission is $2.50. Inside tables for exhibitors and vendors available. Talk-in on 146.52 and 147.81/.21.

BERRYVILLE VA
AUG 3

The Shenandoah Valley ARC will sponsor its 36th annual Winchester Hamfest on August 3, from 7 a.m. to 3 p.m., at the Clarke County Ruritan Fairgrounds on Route 7, two miles west of Berryville, Virginia. Admission is $4, women and children under 12 are free. Tailgaters and limited tables $5. Talk-in on 146.22/.82 and 146.52 simplex. For further information, call Rob Kinsley NT4S at (703)-869-5113, or write SVARC at PO Box 139, Winchester VA 22601. Exams on August 2 at 9 a.m.—call Walt Quitter NC4B at (703)-869-5241, or send an SASE to 367 Buckingham Drive, Stephens City VA 22655.

WEST MIFFLIN PA
AUG 3

The South Hills Brass Pounders and Modulators ARC will hold its 49th annual hamfest on August 3 at the south campus of Allegheny Community College, located in West Mifflin, Pennsylvania, about seven miles south of Pittsburgh. Talk-In on 146.13/.73 and 146.52. For further information, contact Doug Wilson WA3ZNP, 185 Orchard Avenue, Emsworth PA 15202; (412)-761-1851.

49TH SOAP BOX DERBY
AUG 7–9

The Cuyahoga Falls ARC will operate special-event station W8VPV on August 7–8, from 6 p.m. to 11 p.m. EDT each day, and on August 9 from 9 a.m. to 3 p.m. EDT, at Derby Downs, Akron, Ohio, for the 49th running of the All American Soap Box Derby. Evening frequencies are 7.250 and 3.940. Daytime frequencies are 7.250 and 14.270. For a certificate, send a 9 x 12 SASE to W8VPV, PO Box 614, Cuyahoga Falls OH 44222, by September 15.

RIPLEY WV
AUG 9

The Jackson County ARC will sponsor its 9th annual hamfest on August 9 at the Jackson County Junior Fairgrounds, six miles west of Ripley, West Virginia. Admission is $3. Talk-in on .07/.67. For futher information, contact Les Shockey WB8SNO, RFD 2 Box 36, Sandyville WV 25275.

INDIANAPOLIS IN
AUG 9

The WA9SNT ARC will hold its annual swapfest on August 9, from 8 a.m. to 4 p.m., at ITT Technical Institute (across from the pyramids) in Indianapolis, Indiana. Flea-market setup begins at 6 a.m. Admission $2, students $1. Flea-market space $1. Talk-in on 146.94. For additional information, contact Dave Johnston K9HDQ, c/o ITT Technical Institute, 9511 Angola Court, Indianapolis IN 46268; (317)-875-8640.

JACKSONVILLE FL
AUG 9–10

Six major ARCs will sponsor the 13th annual Greater Jacksonville Hamfest and Northern Florida ARRL Section Convention, from 9 a.m. to 5 p.m. on August 9 and from 9 a.m. to 3 p.m. on August 10, at the Civic Auditorium on Water Street in downtown Jacksonville. Registration is $4, children under 16 free. Swap tables are $9 per day or $15 for the weekend. Exams at 1 p.m. on August 9—free for Novice, others $4. Talk-in on the W4IZ (.16/.76) repeater. For commerical booths and swap tables, send inquiries to Greater Jacksonville Hamfest, PO Box 10623, Jacksonville FL 32207; (904)-350-9193.

ESSEX JUNCTION VT
AUG 9–10

The Burlington ARC will celebrate its 50th Anniversary at the Burlington International Hamfest on August 9–10, all day both days, at the Champlain Valley Fairgrounds in Essex Junction, Vermont. Admission $4 U.S., $5 Canadian. Children under 12 free. Campers $5 U.S. per night. Talk-in on 146.34/.94. For more information, contact Barb Kimball N1DLE, 1 Sundown Drive, Williston VT 05495; (802)-878-5555.

MARION IN
AUG 10

The Grant County ARC will hold its 7th annual hamfest August 10 at the 4-H Fairgrounds in Marion, Indiana, beginning at 8 a.m. $2 donation in advance, $3 at the gate. $2 reservation for an 8-foot table. License exams will be given. For more information or tickets, send an SASE to Brooks

Clark WB9EAP, 2202 South Boots Street, Marion IN 46953.

ST. CLOUD MN
AUG 10

The St. Cloud ARC will hold a hamfest August 10 at Lake George in St. Cloud, Minnesota, near downtown, off MN 23 and U.S. 52. $3 ticket donation. Talk-in on .34/.94 primary, .615/.015 secondary. For more information, contact SCARC, Box 141, St. Cloud MN 56302.

WARRINGTON PA
AUG 10

The Mid-Atlantic ARC will hold its annual hamfest on August 10, 8 a.m. to 3 p.m., at the Bucks County Drive-In Theatre, Rte. 611, Warrington, Pennsylvania, five miles north of the Willow Grove Exit on the PA Turnpike. Tailgate setup begins at 7 a.m. Admission is $3 with $2 additional for each tailgate space. Tables not provided. Talk-in on WB3JOE/R (147.66/.06) or 146.52. For information, write MARC, PO Box 352, Villanova PA 19085, or call Bob Josuweit WA3PZO at (215)-449-9727.

GEORGETOWN KY
AUG 10

The Bluegrass ARS will hold the Central Kentucky ARRL Hamfest on August 10, from 8 a.m. to 4 p.m., at Scott County High School, Longlick Road and U.S. Rte. 25, Georgetown, Kentucky. Admission $4 in advance, $5 at the door. Outside flea-market space free. Technical forums, exams, and exhibits. Talk-in on .16/.76. For information or tickets, send an SASE to Scott Hackney KI4LE, 629 Craig Lane, Georgetown KY 40324.

LANCASTER OH
AUG 10

The Lancaster and Fairfield County ARC will hold its annual hamfest on August 10, from 8 a.m. to 4 p.m., at the Fairfield County Fairgrounds in Lancaster, Ohio. Admission $3 in advance or $4 at the door. Limited tables $4 in advance or $5 at the door. Table space $3 in advance or $4 at the door. Talk-in on 147.63/.03 or 146.52 simplex. For more information, write to Lancaster ARC, Box 3, Lancaster OH 43130.

WILLOW SPRINGS IL
AUG 10

The Hamfesters RC will hold its 52nd annual hamfest on August 10 at Santa Fe Park, 91st and Wolf Rd., Willow Springs, Illinois, to celebrate its 53rd year of service to ham radio in the Chicago area. Gates open at 6 a.m. $3 donation in advance, $4 at the gate, children under 15 free. $25 donation from exhibitors per 8-foot table in the pavilion. Talk-in on 146.52. For tickets, send an SASE and check to PO Box 42792, Chicago IL 60642. For general information, call (312)-598-4802.

LOUISVILLE OH
AUG 10

The Tusco W8ZX and Canton W8AL ARCs will present the 12th annual Hall of Fame Hamfest on August 10 at the Nimishillen Grange, 6461 Easton St., Louisville, Ohio. Registration is $2.50 advance, $3 at the gate. 30" by 96" tables available at $5 each (must reserve by August 1). Talk-in on 146.52/.52 and 147.72/.12. For more information or reservations, contact Bill MacNealy WD8LFM, RR#1 Box 442, Bolivar OH 44612; (216)-874-3483.

CAMP FORREST REUNION
AUG 15–16

The Middle Tennessee ARS will hold its first national reunion at Camp Forrest in Tullahoma, Tennessee, to commemorate the camp's use as a training center and POW camp during WWII. The club will operate station W4UOT from 6 p.m. to 10 p.m. (CDT) August 15 and from 1 p.m. to 10 p.m. (CDT) August 16. Frequencies: SSB—3.860, 7.235, and 14.240; CW—3.737 and 7.137. For more information or a commemorative certificate, send an SASE and QSL to George Stone WD4CYV, 712 First Ave., Tullahoma TN 37388; (615)-455-5993.

BREWSTER NY
AUG 16

The Putnam Emergency Amateur Repeater League is having its Electronics Extravaganza on August 16 at the J. F. Kennedy Elementary School in Brewster, New York, from 9 a.m. to 4 p.m. Admission is $3, children under 12 free with adult. Indoor tables $10 (with one admission), tailgating $5. FCC exams. Talk-in on 144.535/145.135. For information, contact R. Dillon N2EFA, RFD#7, Noel Court, Brewster NY 10509.

RHINELANDER WI
AUG 16

The Northwood ARC will hold a swapfest on August 16, at South Park School, 511 South Pelham St., Rhinelander, Wisconsin, from 9 a.m. to 3 p.m. Setup begins at 8 a.m. Admission is $1. Talk-in on 146.34/.94. Exams given for Tech and above, $4. For more information, contact Leonard Bauman K9RMN, 1312 Dorothy St., Rhinelander WI 54501; (715)-369-3296.

ROCHESTER IBM 30TH
AUG 16

The IBM RC will operate special-event station WD0GNK on August 16 from 1400–2100 UTC to celebrate the 30th anniversary of the IBM Corporation in Rochester, Minnesota. Frequencies: phone—14.240, 7.280; CW—7.140; and 146.22/.82. For a certificate, send a QSL and SASE to WD0GNK—IBM RC, IBM Corp., Department 868, Highway 52 North, Rochester MN 55901.

GREEN BAY WI
AUG 16

The Green Bay Mike & Key Club will hold its summer swapfest on August 16 at a new location: Community Service Center, 1673 Dousman St., Green Bay, Wisconsin (take the Dousman/Shawano Ave. Exit off Highway 41). Doors open at 7 a.m. Free admission. 8-foot tables $5; four-table limit (by reservation only; send SASE with name, call, address, and check payable to Green Bay Mike & Key Club, c/o Cathy Strommen KD9WO, 1500 Main St., Green Bay WI 54302). Exams given (register with Larry KD9IA, 1005 S. East St., Apt. 111, Appleton WI 54915). Talk-in on 147.72/.12 and 147.96/.36.

RAILROAD DAYS
AUG 16–17

Great Plains ARC station KC0CP will operate from Oelwein, Iowa, in conjunction with Railroad Days. Frequencies will be 14.235, 7.235, and 3.970, ±10 kHz. For a certificate, send QSL and SASE to KC0CP, Box 203, Oelwein IA 50662.

HUNTSVILLE AL
AUG 16–17

The Huntsville, Alabama, RC will hold Alabama's largest hamfest on August 16–17, at the Von Braun Civic Center, beginning at 9 a.m. each day. Admission is free, flea-market tables $8. Talk-in on 146.34/.94. Exams Saturday at 9 a.m. at the Huntsville High School. For further information, call Frank Brown at (205)-852-6324 (motels), Alen Forney at (205)-837-5936 (dealers), or Dave or Gwenn Givens at (205)-883-2760 (flea market).

TACOMA WA
AUG 16–17

The Radio Club of Tacoma (W7DK) will celebrate its 70th anniversary at the 18th annual Tacoma Hamfair, August 16–17 at the Pacific Lutheran University in Tacoma, Washington. Registration $5, banquet $10, dormitory rooms $14 (single) or $20 (double), reserved parking $2. Exams given. Talk-in on 147.28. Register with Grace Teitzel AD7S, PO Box 45079, Tacoma WA 98445, or call Eva Anderson WB7QNS at (206)-564-8347.

SAN ANGELO TX
AUG 16–17

The San Angelo ARC will celebrate the Texas Sesquicentennial at the CENTEX Hamfest '86, August 16–17, at the San Angelo Convention Center. Preregistration is $5, $7 at the door. Exams given. Talk-in on 3.922, 7.213, .52, and .34/.94. The club will also operate special-event station W5QX. Commemorative QSL cards are available. For more information, write to SAARC, Box 3751, San Angelo TX 76902.

GEORGETOWN DE
AUG 17

The Sussex ARA will sponsor the Delmarva Hamfest on August 17 at Del. Tech. Community College, from 8 a.m. to 4 p.m. The college is located west of Georgetown on Delaware 18, a quarter mile from the U.S. 113 intersection. Advance registration is $2.50, $3 at the gate. Inside tables are $3, tailgating $2. Exams given. Talk-in on 147.075 and 146.52. For information and advanced ticket registration, write Delmarva Hamfest, Rte. 2, Box 244G, Georgetown DE 19947.

ARGOS IN
AUG 23

The Marshall County ARC will hold its hamfest on Saturday, August 23, at the Marshall County 4-H Fairgrounds on State Rte. 10 between U.S. Bypass 31 and Business 31, from 8 a.m. to 2 p.m. Advance tickets $2, $3 at the door. Indoor and outdoor areas; numerous electrical outlets; 8-foot tables $5. For further information, write the Marshall County ARC, PO Box 151, Plymouth IN 46563, or call Bob Nellans KB9DE at (219)-892-5224.

OAKLAND NJ
AUG 23

The Ramapo Mountain ARC

(WA2SNA) will present its 10th annual flea market on August 23 at the Oakland American Legion Hall, 65 Oak Street, Oakland, New Jersey, 20 miles from the GW Bridge. Admission $1, non-ham family members free. Indoor tables $6.50, tailgating $3. Talk-in on 147.49/146.49 repeater and 146.52 simplex. For info and advance space reservation, send an SASE to Frank Lee KA2ALS, 989 Crystal Lake Terr., Franklin Lakes NJ 07417; (201)-337-2290, or Tom Risseeuw N2AAZ, 63 Page Drive, Oakland NJ 07436; (201)-337-8389 (after 6 p.m.).

ITHACA NY
AUG 23

The Tompkins County ARC will sponsor its annual Finger Lakes Hamfest August 23 from 8 a.m. to 4 p.m. at the Trumansburg Fairgrounds, 12 miles northwest of Ithaca, New York, on Rte. 96. $3 admission and $1 for flea-market space. Reserved indoor tables $5 each. Children under 14 free. Talk-in on .37/.97 or .52. For information, contact David G. Flinn W2CFP, 866 Ridge Rd., Lansing NY 14882; (607)-533-4297.

DAYTON OH
AUG 23–24

The Dayton Microcomputer Association will hold Computerfest '86 on August 23–24 from 10 a.m. to 6 p.m. at Dayton's Hara Arena, located off I-75 at the Needmore Exit (#58). Admission is $2, children under 12 free. Flea-market spaces $10 before July 1, $15 afterwards. For more information or to reserve space, call Mark Hanslip at (513)-268-7225, or write to Computerfest '86, 143 Schloss Lane, Dayton OH 45418-2931.

VIRGINIA BEACH VA
AUG 23–24

The 1986 ARRL Roanoke Division Convention and 11th annual Hamfest and Computer Fair will be held August 23 and 24 from 9 a.m. to 5 p.m. at the Virginia Beach Pavilion. Admission is $5 in advance, $6 at the door. Flea-market tables $5 per day, electricity $10 extra for both days. Pre-registered exams given Sunday at 9 a.m. For information and tickets, contact Manny Steiner K4DOR, 3512 Olympia Lane, Virginia Beach VA 23452; (804)-340-6105.

ST. CHARLES MO
AUG 24

The St. Charles ARC will sponsor HAMFEST86 on August 24 at Blanchette Park (new site) in St. Charles, Missouri, from 7 a.m. to 2:30 p.m. Free admission. $2 donation for tailgate flea market. Forums and FCC exams at 10 a.m. Talk-in on 146.07/.67 repeater, 146.52 simplex. For more information, contact Eric Koch NF0Q, 2805 Westminister, St. Charles MO 63301; (314)-946-0948.

SAGINAW MI
AUG 24

The Five County Swap-N-Shop committee of Michigan will sponsor its 10th annual Swap-N-Shop August 24 at the Saginaw Civic Center, beginning at 8 a.m. Advance tickets $2, $3 at the door. $7.50 for an 8-foot table, $3 per car for a covered "trunk sales" area. Talk-in on 147.84/.24 and 146.52. For more information, call Don at (517)-893-3475. For advance tickets and table reservations, send check to Five County Swap-N-Shop, PO Box 1783, Saginaw MI 48605-1783.

MARYSVILLE OH
AUG 24

The Union County ARC will present the 10th annual Marysville Hamfest and Auction on August 24 at the Fairground in Marysville, Ohio (near Columbus). Gates will open at 6 p.m. on Saturday for free overnight camping. Advance tickets are $3, $4 at the gate, children are free. $1 per 10-foot flea-market space, electric power is $2 extra. No tables available. Talk-in on 146.52 or 147.99/.39. For further information, contact Gene Kirby W8BJN, 13613 U.S. 36, Marysville OH 43040; (513)-644-0468. Include an SASE.

BLUEFIELD WV
AUG 24

The East River ARC will sponsor the Bluefield Hamfest on August 24 from 9 a.m. to 3 p.m. at the Brushfork Armory, one mile north of Bluefield, West Virginia, on U.S. 52. Admission is $4, children under 12 free. Walk-in exams at 9 a.m. Talk-in on 144.89/145.49 and 146.52. For more information, write to Jim Perdue KC8NG, Rte. 5, Box 457, Bluefield WV 24701.

CAMP HILL PA
AUG 24

The Central Pennsylvania Repeater Association will hold its annual Electronic Exhibit/Ham/Computerfest on August 24 at the Penn Harris Inn and Convention Center, Routes 11 and 15, Camp Hill, Pennsylvania. Gates open at 8 a.m. $4 admission, XYLs and children under 12 free. Exams begin at 9 a.m. Talk-in on 145.47 (WA3KXG) and 146.52. For hotel reservations, call Penn Harris Inn & Convention Center at (717)-763-7117; mention CPRA for reduced rates. For more information or reservations, contact Paul McDonnell N3BKI, 1207 Apple Drive, Mechanicsburg PA 17055; (717)-697-1880 (12 noon to 8 p.m.).

MULLICA HILL NJ
AUG 24

The Gloucester County ARC will celebrate its 27th year at its 8th annual hamfest on August 24 from 8 a.m. (7 a.m. setup) to 4 p.m. at the Gloucester County 4-H Fairgrounds, Rte. 77, Mullica Hill, New Jersey. Tickets are $3.50 in advance, $4 at the gate. Sellers additional $4 per space or $4.50 with ac power. Indoor tailgating. Exams at 9:30 and 1:30 at Stephen's Hall. Talk-in on 147.78/.18 and 146.52. For information and advance tickets, write to GCARC, PO Box 370, Pitman NJ 08071, or call John K2FJ at (609)-589-2318, Milt K3WIL at (609)-845-7000 (daytime), or Ginny Martin N2FJM at (609)-694-4442 (evenings).

LABOR DAY TRAVEL
AUG 30–SEP 1

The Tri-City ARC will operate special-event station KA1BB from the Waterford, Connecticut, I-95 weigh station to promote safe Labor Day holiday auto travel. This event is in conjunction with the fourth annual Stay-Awake Coffee Stop offered by BSA Troop 24 of Niantic CT. Mobile operators are especially encouraged to call. Operation will be from 1700 UTC August 30 through 2300 UTC September 1 on 14.295, 7.245, and 3.395 (phone) and on 7.130 (CW). Talk-in to coffee shop on FM 146.52 direct and CB channel 19. QSL via Tri-City ARC, PO Box 686, Groton CT 06340. For information, please contact Bob Dargel KA1BB, 8 Willow Lane, East Lyme CT 06333; (203)-739-8016 or (203)-446-7325 (work).

OK CORRAL
AUG 30–SEP 1

The Old Pueblo RC will operate its 5th annual special-event station W7GV from 1300 UTC August 30 to 2200 UTC September 1, from the famous OK Corral at Tombstone, Arizona, site of the famous shoot-out between the Earps and Clantons in 1881, in celebratrion of the Rendezvous of the Gunfighters. Frequencies: SSB—21.380, 14.280, 7.280, and 3.980; CW—14.060, 7.130, and 3.730. Send a QSL with an 8-1/2 x 11 envelope and 40 cents postage to W7GV, PO Box 42601, Tucson AZ 85733.

LEBANON TN
AUG 31

The Short Mountain Repeater Club will sponsor the Lebanon Hamfest on August 31 at the Cedars of Lebanon State Park, U.S. Highway 231, Lebanon, Tennessee. Bring your own tables. Talk-in on 146.31/146.91. For further information, contact Mary Alice Fanning KA4GSB, 4936 Danby Drive, Nashville TN 37211.

LANCASTER PA
AUG 31

The Red Rose Repeater Association will hold a computerfest on August 31 from 9 a.m. to 3 p.m. at the Guernsey Sales Pavilion, four miles east of Lancaster on Rte. 30 at Rte. 896. $3 donation, children under 14 free when accompanied by an adult. Talk-in on 147.015. For information, send a SASE to Computerfest Committee, PO Box 5029, Lancaster PA 17601.

SCHAUMBURG SEPTEMBERFEST
AUG 31

The Schaumburg ARC will operate club station WB9TXO on August 31 from 1600–2100 UTC from the grounds of the Schaumburg Septemberfest. Suggested frequencies are 7.286, 14.286, and 21.386. For a certificate, send a QSL to SARC, PO Box 94251, Schaumburg IL 60194.

BLOOMINGTON IN
AUG 31

The 9th annual Bloomington Hamfest will be held on August 31 from 8 a.m. to 2 p.m. at the 147.78/.18 repeater site at 2335 Vernal Pike off the SR 37 bypass. Admission $2. No tables available. Exams given. For further information, contact Bob Myers K9KTH, 306 S. Fairview Street, Bloomington IN 47041; (812)-332-1105. Include an SASE.

NORWALK CT
SEP 7

The Fairfield, Norwalk, Stamford, and West Haven ARAs will sponsor the Fairfield County Hamfest on September 7 from 9 a.m. to 5 p.m. at the Norwalk National Guard Armory, off Exit 38 Merritt Parkway. Admission is $3, tailgating $5, tables $10, power free. Talk-in on 147.39/.99 and 146.52. To register, write to PO Box 326, West Haven CT 06516.

VK7 QSL BUREAU

From Chas Harrisson VK7CH comes an interesting report on the last three years of the VK7 QSL Bureau.

A point of interest is that there appears to be a 3,000-card shortfall each year between cards coming in and cards going out. A second point that affects all amateurs waiting for their VK7 cards, whether it be for their "Tassie Devil" award or just a confirmation, is the time delay the bureau has waiting for packets of cards from overseas bureaux. QSL cards for the last three years are shown in Table 1. The peak year was 1980, with a total of 49,062 cards.

In and out cards are inflated this year by 7–8,000 by cards received from overseas bureaux for VK75A, the special anniversary call, and these had to be sent on to VK3.

A noticeable number of overseas bureaux now send cards at longer intervals. Only two lots have been received during the year from both the U.S.A. and U.S.S.R.

MACQUARIE ISLAND

In another snippet from VK7 comes the news that Sjored VK7ZSJ, or "Sojo" as he is called by his friends, left Hobart in early March for Macquarie Island, where he will stay for the winter and will operate as VK0SJ for at least the next nine months. He will take his HF gear, with the TONO for RTTY and 2m gear for the robot satellites.

A keen group of VK3ers have pooled in and given Sojo, on loan for the year, a callsign keyer for the 2m and 6m beacon, a 6m transceiver, a 6m and 2m linear, 6m and 2m yagis, and power supplies. So, says Sojo, "Keep an ear out" on the 6m and 2m bands for the beacon. The exact frequencies will be announced when the equipment is installed and minimum interference with scientific equipment is determined.

If you are interested, keep an ear out on his regular HF skeds with VK7VK, VK7HK, or VK7RM around 0900 UTC on 14.120 MHz, also on Mondays and Fridays at 0930 UTC on 7.085 MHz. QSL is via VK7RM; no CW as Sojo has a limited call in VK.

Why no CW, you might ask? Australian amateurs have been granted a concession by our DOC. Those holding a lower class license than the full call (e.g., Novice, Limited, or a combination of both) are granted full call license privileges while operating from remote areas such as Antarctica, Willis Island, Heard Island, etc., for the duration of their stay in these places. Their license automatically reverts back to their original class when they leave. As Sjored is very, very competent technically, all the limited license means is that he has never either sat for or passed the CW examination to upgrade to full call privileges within Australia.

PREDECESSORS PRAISED

At the WIA's 75th Anniversary Dinner, Mr. R.E. Butler, Secretary General of the ITU, in front of an assemblage that included our Governor, plus other distinguished people, gave praise to our sometimes forgotten experimenters of the past. He stated that he was "deeply honored [to speak before] the oldest institute of its kind in the world."

Mr. Butler noted that amateur radio was the only hobby provided for by the International Telecommunications Convention, which defined it as an activity carried on by duly authorized persons interested in radio technique "solely with a personal aim, and without pecuniary interest." This provided a precedent for the 1971 naming of the Amateur Satellite Service at the World Administrative Radio Conference for Space Telecommunications.

The Secretary General said that the worldwide recognition emerged over decades from the solid and reliable characters of renowned radio enthusiasts in Australia and elsewhere. Even before the WIA, came "the example and brilliance of Sir Charles Todd and his team for . . . the overland telegraph," he noted, adding mention of the first public demonstration of wireless telegraphy by Professor William Bragg in 1897, at the University of Adelaide.

Lauding the regularly received help over the years from the "Post Office," Mr. Butler then recalled the names and exploits of Jenvey, Bartholomew, Maclurcan, Read, Coxon, Davis, Traeger, Reverend Flynn, and Sidney Witt. He spoke of "Fisk and Hooke, and a legion of talented engineers" without whom there never could have developed The Flying Doctor Service, School of the Air, civil aviation, or The Public Telegraph Service, not to mention the many outback centers' services.

Remarking that radio amateurs were involved in exploring space long before its material use, he concluded, "Allow me to salute the predecessors who set the promotion of the radio techniques in action and I wish the institute long service and prosperity."

	1985	1984	1983
Cards received	10,455	11,015	16,300
Cards sent	7,096	7,672	11,696
Total	17,551	18,687	27,996

Table 1. QSL cards.

AUSTRIA

Osterreichischer
Versuchssenderverband
Theresiengasse 11
A-1180 Vienna
Austria

The O.V.S.V. (an IARU member) announces its Austrian prefix contest (AOEC 160m), which will take place the third weekend in every November, 1800 UTC Saturday to 0700 UTC Sunday, on 1810–1950 kHz. (Participants must be careful to observe their national regulations for 160m!)

CW only, licensed radio amateurs worldwide (in Austria, OVSV-members only) and SWLs are eligible. Contest call: CQ TEST/CQ OE; exchange: RST and serial number starting with 001; Austrian stations give RST and a three-digit number for the individual ADL (Austrian District Locator).

Count one point for each contest QSO, with multipliers: each worked Austrian call area 2, and 1 multiplier count for each ADL and for each prefix worked. The total score is the sum of all QSO points times the sum of all multiplier points. Log format for reporting should be A4 size, written on one side only. The AOEC standard log and summary sheet is preferred and may be requested (forms 017 and 018). Write to OVSV-AOEC160m at the above address.

Please send entries to OVSV-AOEC160m also, postmarked no later than December 31 of the contest year, accompanying the summary sheet(s) with the statement: "I declare that this station was operated strictly in accordance with the rules of the contest as well as within the national radio regulations."

Unmarked duplicate logsheets will not count and will result in a 5-point reduction in score. Certificates will be awarded to the 10 leading entries from each continent; results will be reported to IARU Region 1 and each society from which came entries.

FRANCE

Claude Guee FD1DGY
11 Rue Emile Labiche
28100 Dreux
France

After a long silence due to a car crash and some other QRM, here is some news from France, for a *73* Magazine that is more and more interesting! Bravo!

NEW CALLS

You can hear calls like FB1XYZ between 7.020–7.040, 14.050–14.100, 21.050–21.150, and 28.000–28.100. These are QRP stations—20 Watts—and new beginners. Without code tests, these beginners should be FA1XYZ, with only some channels on the

2-meter band and without repeater access.

Test exams are now carried out on the "Minitel" system, in different centers. (This is the French directory computer system issued from the PTT, allowing for a lot of services including this opportunity for direct examinations.) According to the authorities, only 30% of the candidates are failing, and these mainly because of lack of knowledge of the rules and regulations. Generally speaking, the candidates prefer this system; results show that a radio-club training is very helpful for the successes.

Another use of Minitel: Owners of terminals can receive directly from CNET propagation conditions, which are updated every day.

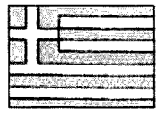
RECIPROCAL AGREEMENTS

There now are reciprocal operating agreements between Luxembourg, Monaco, West Germany, and France: licenses now are permanent. Maybe this is a first step toward a full European license. Others should apply to: DTRE CGRP, Service Amateur, BP 75, 94002 Creteil Cedex, France. Your call in France will be, for example, F/W, for at least three months (and for a year, eventually). The former F0 calls do not exist anymore. Countries now having reciprocal agreements with France are Australia, Austria, Belgium, Brazil, Canada, Denmark, Greece, Israel, Italy, Ivory Coast, Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom, the U.S.A., and Yugoslavia. Under negotiation are agreements with Argentina, Monaco, Ireland, Oman, and Japan.

MISCELLANY

The **QSL Bureau** via Reseau des Emetteurs Francais (REF) address now is BP 273, 81209 Mazamet, France. While HQ is still in Paris, some activities are being decentralized to save money.

SWLs have received an official call after waiting for years. Now they can send nice QSL cards, like F11XYZ. Other modifications include FF for club stations—for example, F6KXY becomes FF6KXY; Corsica is IK instead of FC; Antarctica and Australs Islands are FT instead of FB.



Law Story: Very bad news—now it is not allowed to install any aerial of a size bigger than 4 meters (13 feet) without authorization, for reception or emission. No minibeam but now microbeam!

Arsene: The French amateur satellite is alive and the launch should be scheduled by the end of the year. Two modes will be available: B and F.

F0OX (Clipperton Harbor) will become a permanent base. Two months ago the French government announced a project of a harbor for fishing boats on this famous atoll. This would mean the end of one of the most attractive DX contacts . . . but wait and see. . . .

TP21. Conseil de l'Europe, Strasbourg, France: This new call is not yet on the air. Delayed due to an unexpected amount of formalities. (CDXC information.)

Best 73 from France.

GREECE

Manos Darkadakis SV1IW
Box 23051
Athens 11210
Greece

In my previous column, I analysed the hardware of our newest repeater (R0) and I will continue here to describe its software part, too. Speaking about the software, somebody might wonder why it was necessary. The answer is because the repeater is far away from Athens on a mountaintop, some 1,600 meters above sea level, and besides that, it is very difficult to go during winter time because of the snow, even for the two local hams in Kalamata, a nearby city.

Let's see now what the logic does. At first it checks every two hours the capacity of the batteries, and if the batteries have more than 60 Ah then the R0 is on high power, but if capacity is between 30–60 then R0 switches to low power, and if capacity is lower than 30 Ah then it goes to self-protecting mode during which it sends only its ID if triggered and the telemetry every two hours.

There is no restriction of repeater operating time during summertime, but during winter it depends on many factors. If the photovoltaic panels cannot supply charging current at all, then R0 can operate on high power for three days if operated 4–5 hours daily; after three days, Its logic will switch it to low power and can again be operative for six more days (4–5 hours daily).

If still no current is coming from the panels, it goes to self-protection mode and only sends the telemetry in high power for 25 more days. If things still look gloomy, it then goes to sleep. Every time the repeater sends information about its state during the telemetry, if it is on low power it sends SV3A Low Power. If it is not working because of the batteries, it sends SV3A Idle Mode. And finally, when closed, it sends SV3A Closed.

The whole system can be telecommanded and some corrections can even be made from distance. There is also a station devoted to record every telemetry transmission from it. At the end of the day, all information is entered in a computer and further analysis is made. Useful conclusions can then be extracted in order to help more of these self-contained units to be installed all over Greece.

Additionally, when R0 sends 00 during the hot summer days, that means that the temperature sensor is giving overflow and temperature is over 40 C. If it gives M5 or M10, that means that temperature is below zero—minus 5 or 10.

Finally, the repeater sends its ID after the end of someone's transmission, and, if more than 3-1/2 minutes after the last one was sent, timeout is set on 95 seconds.

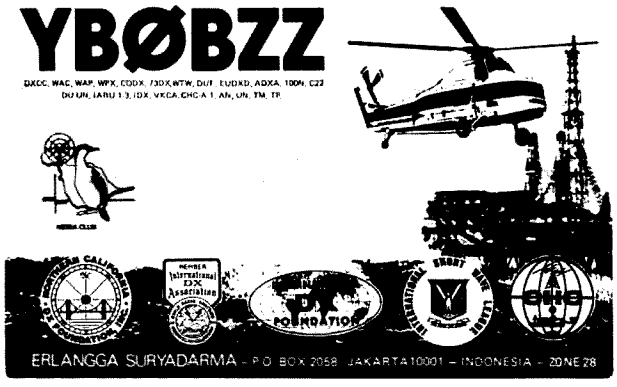
Now, eight months after the repeater's installation, everything goes perfectly OK. We had no problems during winter time, and it looks as if our new friend is very promising as the first member of a new generation of repeaters in our country. We hope to have some more repeaters like this installed here in Greece before long, but don't worry: You'll be the first to know, here in *73* Magazine!

INDONESIA

Erlangga Suryadarma
YB0BZZ/V85BZ
ORARI National QSL Bureau
PO Box 96
Jakarta 10002
Indonesia

(73 International welcomes Indonesia, and its representative, YB0BZZ, QSL Manager and IARU Region III Liaison Officer, who has provided most of the following information. Much of this came from a paper he and Ben S. Samsu YB0EBS prepared for last November's IARU Region III meeting in New Zealand.)

Unlike many neighboring countries, Indonesia has not abolished or curbed all ham activity. All Indonesian hams must by law be members of ORARI (Organisasi Amatir Radio Indonesia), and there are no provisions for guest operators at present.



The Amateur Radio Service began here in the 30s when the country was the Netherlands East Indies. Two pioneers worthy of mention were Rubin Kain YB1KW (licensed in 1932) and B. Zulkarnaen YB0AU (licensed in 1933), silent keys as of 1981 and 1984, respectively.

All amateur radio activity was suspended by the Japanese occupation authorities at the beginning of World War II, but a number of stations went underground fighting for Indonesian independence. When independence was proclaimed in 1945, the declaration was transmitted throughout Indonesia and the world using a "simple homemade revolutionary radio" constructed by Gunwan YB0BD; the rig now occupies a place of honor in Indonesian independence history and is on exhibit in the Indonesia National Museum.

During the next four years (ending December 27, 1949 with the Dutch ceding sovereignty), a young amateur by the name of Syarifuddin built home-brew transceivers, which were used to maintain communications between the Indonesian islands—particularly between Java and Sumatra. He now is a high-ranking professional in the Directorate General of Post and Telecommunications and a supervisor for ORARI.

Internal security problems led to the suspension of any nongovernmental radio services activity from 1950 to 1967. In 1967, the Amateur Radio Service was re-established. At present, amateurs are subdivided into three classes of skill and proficiency, with only the top class being permitted to contact foreign amateur stations. All belong to the "Lokal" (district) level of ORARI, which is part of the "Daerah" (provincial) level of ORARI.

Foreign citizen radio amateurs, upon issuance of a temporary residence permit, are permitted to apply for amateur operating privileges on a reciprocal basis. This is

possible now for nationals of the U.S.A., the United Kingdom, Canada, Australia, the Federal Republic of Germany, the Netherlands, Sweden, Belgium, France, Argentina, and Finland.

Growth of activity was slow between 1967 and 1980 (from about 200 hams to about 5,000), but with some new simplified regulations and new availability of ready-for-use (factory-built) rigs, there was a big rush for amateur tickets. It seems likely that 40,000 will prove to be an accurate figure for earty 1986 despite an alarmingly high dropout rate among the Novices (80% of the total membership of ORARI), about half of whom do not renew their licenses. Burdensome procedures involved in renewing may have a lot to do with this.

ORARI is currently involved in hard work to achieve better structure and organization, simpler regulations, and more professional operation in all ham matters. International *Callbook* material is badly out of date, "and it is suggested that all correspondence and QSLs be handled through the ORARI National QSL Bureau" (address above).

RADIO SOCIETY BEHIND A BAMBOO CURTAIN

The existing general rules for amateurs issued by the Directorate General of Post and Telecommunications were derived from outdated 1968 material—a time when sophisticated UHF/VHF/RTTY/SSTV/AMSAT, etc. were unknown in Indonesia. However, within the last three years, a "gap" has occurred between the rules and common "incorrect practices" of so-called "radio operators."

ORARI has constantly submitted concepts and ideas to improve the existing rules, but the government has to concentrate efforts on the development of a national communications system, so that little attention has been paid to ORARI beyond the regular State Examination to accommodate the enthusiasts. ORARI still hopes, however, that more comprehensive regulations will be available before the end of the year.

While ORARI has 40,000 registered members, only a mere 5% are DXers. The majority squeezed themselves into the crowded VHF/UHF band. This creates the impression of "a radio society behind a bamboo curtain" to the amateurs of the outside world, due to the scarcity of the international contacts established.

A lack of training on DX matters among senior amateurs, some shy and uncertain of their English, did not set an example for younger amateurs to follow. Between 1967 and 1982 the radio society had only seven DXCC holders! With the establishment of training programs in the past two years, 15 DXCC awards have been made, including one 5BDXCC, for a total now of 23.

Continued next month.

THAILAND

Tony Waltham HS1AMH
c/o Bangkok World Newspaper
Soi Saladaeng
Bangkok 10500
Thailand

Amateur radio in Thailand is about to be legalized. Indeed, by the time that you read this it will most likely be a fact, for the final draft of the legislation—the provisions for administration, the separate license classes and required qualifications—has been prepared by the Thai Post and Telegraph Department.

It is not that amateur radio was ever illegal, and no, don't disallow any HS contacts you may have had. It is simply that up until now our hobby has been officially sanctioned only for special events, such as contests. Prior to that, members of the Radio Amateur Society of Thailand operated according to an understanding with the authorities.

Late last year the National Security Council approved amateur radio as being an activity not detrimental to society (or security), thanks to a petition led by the Post and Telegraph Department.

Senior members of the Radio Amateur Society of Thailand have also played an active behind-the-scenes role in getting the activity recognized and legitimized.

In a series of meetings following the NSC's approval of amateur radio in principle, RAST members and senior PTT officials worked out a draft for the regulations and administration of the hobby. At the time of writing, the following salient points regarding amateur radio have emerged:

- The minimum age for applicants for a license will be 15 years of age, and they should be Thai nationals.
- Qualified foreign residents will be able to apply to operate under reciprocal operating privileges to be set up with corresponding administrations abroad.
- A National Security Council or Police clearance would be required before an amateur radio license will be issued, while membership of the Radio Amateur Society of Thailand will also be a requirement as the society will play a major role in controlling the activity, especially on HF.
- Three license classes are envisaged: a Novice class offering VHF only, with the full two-meter spectrum available; a secondary HF class with a Morse code requirement; and a first-class license with Morse code capability both in the Thai language and in English being required.
- Those applying for an amateur radio license will need to be seconded or endorsed as a person of good standing by a member of the radio club.
- A basic knowledge of English will be required for an HF class license. This is to enable Thais to be able to conduct a basic QSO with radio amateurs abroad.

These are just some of the points in the draft for the administration of amateur radio in Thailand which have taken both international and national considerations into account.

RAST also has filed an application with the PTT to operate a club station for demonstration and training purposes after the regular monthly club meetings at the Singha Bier Haus (conducted from 11 a.m. on the first Sunday of each month). Initially, club stations are envisaged by the authorities, with the first two being at the Asian Institute of Technology and at the Science Museum in downtown Bangkok.

It is hoped that operations from private homes will be permitted later, but progress will be on a step-by-step basis; to have a fully legislated amateur radio service in Thailand is an achievement in itself—one for which RAST has been actively campaigning for 22 years.

For most DXers, the best chance to contact Thailand will be during one of the major international contests which the club's members operate with the call-sign HSØA. Typically, we make between 3,000 and 4,000 QSOs in a 48-hour period, and often stateside stations give us reports of 5 and 9 plus 20, "and I'm surprised no one else is calling you."

It seems that all too often U.S. and even European stations swing their beams away from Asia while the band is still open—and miss a chance if they need Thailand or Zone 26.

For everyone's diary, Table 2 shows the major international contests which we intend to participate in over the coming year.■

Date	Contest	Mode
Jun 21/22	All Asia	Phone
Jul 12/13	IARU	Phone/CW (begins 7 p.m. July 12 for 24 hours)
Jul 19/20	SEANET	CW
Aug 16/17	SEANET	Phone
Aug 23/24	All Asia	CW
Oct 25/26	CQWW	Phone
Nov 22/23	CQWW	CW

NEVER SAY DIE

from page 12

tures of the exhibits for use in your next year's brochure?

Remember to send a letter to the exhibitors after the show, getting their input—and possibly some good quotes for your next year's sales pitch. You'll also get some ideas on ways to improve.

The local hams already know about your local attractions, so you don't have to lay that on 'em, but those from further out may know less about it than you think. You might get them to come in Thursday night and spend Friday with their families having family fun—with perhaps a three-hour Friday evening hamfest opener for the commercial exhibits—say 4–7 p.m. This could be the same time the flea marketers come in and set up their tables. The industry meeting could then begin at 7, complete with some snacks.

It's often difficult to get your local hams to come. I frequently hear any number on the local repeaters who aren't bothering. You need to come up with a spiff to get these dead heads off their duffs. Prizes will usually do it. Not so much big ones as a lot of smaller ones and a big to-do about how many prizes there are.

You might think in terms of arranging meetings of special interest groups—and I mean beyond a talk on the program. Do you have a time and place for the 10/10 fanatics to meet? The 12/12ers? The SWOTs? SSTVers? RTTYers? Packet radio? Certificate hunters? DXers? 160m? UHFers? Microwavers? 6m? County hunters? OSCAR users? Repeater owners? Repeater coordinators? Weather satelliters? YLRL? Traffic handlers? Emergency net groups? Give each group a time and place to meet and you'll pull 'em out of the woodwork.

How about having some stickers for each of these fanatic groups available when the hams sign in so they'll be able to spot their fellow fanatics? If you're keeping a data base of the hams who register you can also key in their interest and make it easier to get them back next year with special programs of particular interest to them. Today's computers make this simple.

Now, I mentioned the critical importance of ham dealers. Hams may enjoy getting on the air, but most of all they enjoy buying something new. With enough dealers, your attendees will have a wide variety of ham gear available and at reasonable prices. I suggest, in addition to the usual brochures and mailings, that you call ham dealers and tell them what a bunch of buying fanatics you have ready to unleash on their piles of rapidly aging ham gear inventory. Here's the place to bring the stuff that has been gathering dust—mark it down and turn it into money.

It won't hurt if you can round up a few club members to help dealers move their stuff in (and out, later). Can you provide a club member to relieve smaller exhibitors at their booth so they can get around and see the hamfest for an hour?

To find out how good your speakers are, make up some forms to report on which forums were attended and how interesting they were. This will give you a good idea of how many attended each forum and whether you need to look for someone more interesting next year. You can make sure these reports are handed in at the end of the hamfest by having a special post hamfest drawing.

Well, there are some ideas... let's see what you can do with 1987!

Hmmm, you say you want me to come and give a talk? Sorry, I'm pretty well booked up for 1987. Of course, if you have the budget, I might be able to make an exception. In general I'll be planning to see you at Miami, Orlando, Dayton, Dallas, or Atlanta. Don't let me down. Remember, amateur radio and *73* are at the very best nonprofit ventures for me, so my priorities tend to lean toward digital audio, 8mm video, publishing, and computer shows.■

PACKET RADIO GOES PORTABLE

GLB ELECTRONICS

presents

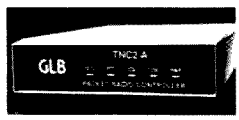
Model PK1-L

- LOW 25 mA Current drain.
- Designed for portable or solar-powered stations.
- Miniature size—Lightweight
- Rugged all metal, shielded enclosure.
- On-board Lithium Battery RAM backup.
- On-board watchdog for reliability.
- Standard DB-25 Connectors.
- Output signal indicates "Connected" Status.
- Does not require squelched audio.
- Comes with 8K of RAM.
- Remote Command Mode for Unattended operation.
- Hardware command lockout for security.
- Commands compatible with our Model PK1.
- Retains all other features of the Model PK1.
- Extra I/O lines for special applications.

Power requirement:
9 to 15 Volts DC @ 25 mA typical

Dimensions:
4.6 X 5.90 X 1.0 inches

Total Weight:
12 ozs.



PKIL—Wired and Tested
List— $209.95
Amateur net— $179.95

Sky Wires!

12 Hot Antenna Projects

Including:

- Slinkies at HF — p. 52
- 90-Foot Rotatable Tower — p. 28
- Coaxial Stub Tuning — p. 54
- Feeds for 10 GHz — p. 46
- Scale-Model Antennas — p. 40

Lossless Wireless — p. 60

Worm-Warmer 75m Quad — p. 66

Simple 9-Band Doublets — p. 32

Money-Saving Home-Brew Traps — p. 56

Table of Contents

A Rotatable *What?*
How to spin 90 feet of crank-up tower on a lazy susan. WA2VUN 28

HF Antennas: All Bands, All Wire
Another round in the crusade against coax—these three 9-band doublets contain no artificial ingredients W0VM 32

Watts My Line
Coax, parallel feeders, or microstrip, this Basic program lets you design your own custom transmission line. K4IPV 36

Scaling the Wet Noodle
Antennas in one-quarter time: Experiment with your favorite 160-meter kludge on 40 meters. W5RRH 40

The Missing Link
Control your entire HF station from the convenience of your HT's tone pad. WB2REM 42

Dishing It Out On 10 GHz
Microwave feed systems and antennas that really cook. WB6IGP 46

High and Dry
You'll literally go through the roof over this beam mounting scheme. WA2OLZ 50

The Ramada Radiator
It fits in a suitcase, covers all bands, and costs under $10 to build. WA8WVF 52

The Texas Tango Antenna
Get two bands for the price of one with a tuned-coaxial-stub dipole. K5BTV 54

Trap An Amazon Aerial
In the jungle, there are no Radio Shacks. Here's how to home-brew your own traps. WB4YOD/PW8ZAF 56

Resonant Wire Antennas
Amateur radio's roots: Take a piece of wire and stick it in your rig. (Well, it's a *little* more complicated than that . . .) W0VM 60

The Lazy U Dipole
Here's what happens when a dipole gets the bends. VE7BS 64

The 75m Laid-Back Quad
What started as a joke ended up being a blockbuster antenna. N4VD 66

Kit Corner: Build A Two-Tube Vintage Receiver
Dick Smith Electronics revives a classic radio. ..... Whitby 68

CoCo's Compu-Charger
Could this be the world's smartest NiCd conditioner? K2OAW 70

Reviews

Does all: ICOM's IC-1271A VHF/UHF multimode transceiver. KT2B 22

SEPTEMBER 1986 ISSUE #312

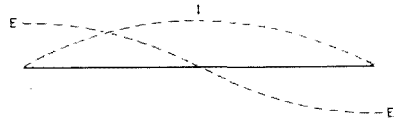
A Rotatable *What?* **28**

There's this 90-foot crank-up tower, see, and it has everything on it, from stacked 23-element yagis for 1296 MHz to a 3-element 40-meter monobander . . . but the wind load's too great to use a commercial rotator. The solution? Easy—put the 90-footer on a lazy Susan and spin the entire tower!

HF Antennas: All Bands, All Wire **32**

The curse of coax is lifted! WØVM vanquishes the black snake with three 9-band antennas. The secret is the use of balanced tuned feeders, a technique all but forgotten by hams who grew up with RG-58U.

Watts My Line **36**



Comes a time when every ham is put to the test. In this case, a nonstandard transmission line had to be fabricated from the materials at hand, a task made easier by the friendly computer. Use this Basic program to design your own lines: coax, parallel feed, shielded parallel feed, and microstrip.

Scaling the Wet Noodle **40**

Bring your next antenna project down to size: Work with a scale model before you erect a full-size skywire.

Dishing It Out On 10 GHz **46**

Construction techniques for building microwave feed systems and antennas, including the serendipitous "plastic baggie" dielectric resonator.

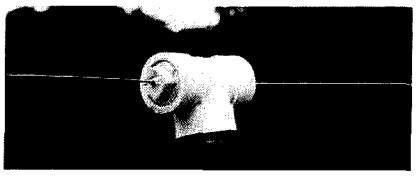
High and Dry **50**

Here's a new twist on the old plumber's delight theme: WA2OLZ describes how to bring your rotator inside the house, and how to erect a 3-element tribander without using a tower.

The Ramada Radiator **52**

A pack-it-up-and-take-it-with-you antenna that works on all bands and costs under $10 to build. (The title of this article came in a sudden flash of brilliance from Managing Editor KA1MPL, whose cousin is known throughout the Midwest as "Ramada Rudy.")

The Texas Tango Antenna **54**



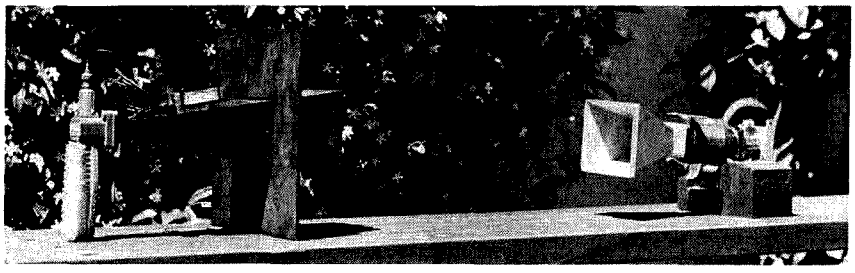
We toyed with the title "The Five O'Clock Shadow Doublet" for this little gem, because of the little black stubs of coax that act as tuned traps in this multiband wire antenna. It's a great way to add the new WARC bands to your favorite dipole.

Trap An Amazon Aerial **56**

Another variation on the trapped dipole, this time with home-brewed capacitors. The prototype for this design was used extensively in the jungles of South America; you can expect years of use here in the states.

Resonant Wire Antennas **60**

Get back to ham radio's roots with a resonant wire antenna—there's no feedline loss since there's no feedline.



The Lazy U Dipole **64**

The continuing evolution of the VE7BS bent dipole. Basically a single-band antenna, the Lazy U could be just what you're looking for on 160 meters.

The 75m Laid-Back Quad **66**

Okay, maybe the idea of a two-element quad pointing straight up seems a bit odd, but consider that, at least with rf, most of what goes up eventually comes down. (If nothing else it will keep your lawn free of snow in the winter.)

Extra copies of this issue are available for $4.50—send a check or money order to *73* Back Issues, WGE Center, Peterborough NH 03458-1194.

Contract: The mere possession of this copy of *73* is hereby declared a legally binding contract between you (contractee) and the publisher (contractor). As contractee you have several responsibilities. First, unless you are an Extra-class licensee, you are hereby directed to start preparing for your next higher license exam. If you are already an Extra, you are directed to start really learning the theory you just memorized to pass your exam. Second, you are to agitate your radio club to sponsor a radio club in a nearby school. If you are not a member of your local radio club, join immediately. If there is no local radio club, start one. You are to report your progress to the contractor on the last day of every month. Send your report to Wayne Green, WGE Center, Peterborough NH 03458.

NEVER SAY DIE

GETTING THE WORK YOU WANT

You say you're not excited and raring to go when you go to work in the morning? If your work isn't fun, you're in the wrong work. If you're not getting to work early so you can get at it. . . if you're not one of the last out at night because you hate to leave, you're losing out on a lot of the fun of life.

Work is fun for millions of people. Work is misery and aggravation for millions more—millions who just have never stopped for a while to think things out. If you leave your life entirely to chance and make no effort to plan it, then you have no beef. Anyone so lazy that they won't make an effort to make life better for themselves should shut up and take life's beatings passively.

What's this got to do with amateur radio? A lot, good friend. Now, just the fact that you've managed to get your ham ticket sets you apart from the average schmo (Yiddish for a foolish or stupid person). However, if you're whining about the cost of ham gear or the cost of a *73* subscription, it's time for you to take stock of your life. If you're short of money you're not doing it right.

Considering all the potential amateur radio has provided you for developing a career—unless you Bashed your way in and really don't know diddly—you should be able to do very well. Electronic technicians are desperately needed today.

But no matter what your field of expertise. . . say, you *do* have some expertise, don't you? If not, that's a big part of the problem. If not, for heaven's sake take some aspect of amateur radio and become an expert on it. It isn't difficult. I've become an expert on NBFM, SSB, repeaters, RTTY, computers, and so on. If I can do it, so can you.

Once you're an expert you can use that to further your career. How do you know when you're an expert? Well, you'll know. It's when you can work from experience and facts rather than firmly held convictions. It's when you get published.

Speaking of being published . . . as a good general rule, when you're changing jobs you'll find that each article you've had published in your field of expertise will bring you about $1,000 a year more in salary. I'll bet that got your attention!

Okay, let's say you've picked a career path where your experience in amateur radio will help you. Let's say you've become an expert on something. . . perhaps slow-scan television. . . or packet radio. Now you want to use that expertise at work. Once you find a company doing the sort of thing you're interested in, how can you get a job there?

No matter what job you want, if you know you're really qualified and that the firm will benefit by hiring you, you can get a job. I don't care if there are no job openings. I don't care if the firm has a hiring freeze. If you want to work there and you spend some time planning your approach, they're dead meat.

The simple, but least productive, way to get a job is to walk in and apply for it. If you've come at the right time they may have an opening. Fine, but unless that opening is just what you're looking for, you're going to be stuck doing something other than your dream job.

It's not all that difficult to get the job you really want, whether the firm knows it needs you or not. All

EDITED BY PERRY DONHAM KW1O

220 Try

ANOTHER ATTEMPT to garner space on the amateur 220-MHz band has been made by the **Association of Radio Reading Services (ARRS)**. The ARRS is a volunteer organization that currently uses commercial FM subcarriers to broadcast text to the reading-impaired. Recent changes in the rules governing subcarrier use make it easier for broadcasters to deny space to groups such as the ARRS; the remaining stations are charging more and more for the use of their transmitters. The ARRS is asking the FCC to set aside ten 50-kHz channels in the amateur 220-MHz band for the reading service. Transmitters would be limited to an output of 1,000 Watts, and antenna height would be restricted to 1,000 feet. The allocation would be primary, with amateur radio coexisting on a secondary, noninterference basis. In an interview published in *220 Notes*, Robert Watson W0YOC, one of the authors of the proposal, said that the idea to use 220 MHz was originally put forth by the NTIA, a group currently involved with the FCC in a joint study of the future of the 220-MHz band. Watson went on to say that the ARRS had conducted an informal survey of the level of amateur activity on 220 MHz, and that on the basis of that survey felt that the ARRS and ham radio could share spectrum. The ARRS feels that theirs is a service very similar in nature to the public-service role played by amateur organizations. The ARRS proposal (RM-5434) joins the growing list of petitions seeking space on the 220-MHz band, including PR Docket 86-161, the Novice Enhancement package. No action is expected on any of the pending petitions until the joint FCC/NTIA study is completed. PR Docket 86-161 should be acted upon before year's end, but only the 28- and 1,296-MHz portions will become effective. . . it could be years before the situation on 220 MHz is straightened out. If you'd like to comment on the ARRS proposal, you can file informally by sending a letter, or you can file formally by sending an original and 12 copies to the commission. If you opt for a formal comment, you also need to send a copy to J. Brian DeBoice, Cohn and Marks, 1333 New Hampshire Ave. NW, Suite 600, Washington DC 20036 (DeBoice is the attorney for the ARRS). You'll also need to include an affidavit with your material stating that you have forwarded copies to Cohn and Marks. The FCC's address is 1919 M Street NW, Washington DC 20554. (An example of the format to use appeared on page 89 of the July, 1986, issue of *73*.)

Ten Matters

BOB HEIL K9EID has proposed changes in the ten-meter FM band plan. The new plan calls for ten repeater pairs on 400-kHz splits and 20-kHz spacing with inputs from 29.100 to 29.280 MHz. 29.300 to 29.400 would be used only for simplex contacts, while 29.400 to 29.500 MHz remains reserved for OSCAR mode-A downlinks. (Eventually, mode-A use will be discontinued, and the space used for simplex operation.) Bob suggests a 50-Watt limit in the repeater subband. Things are pretty quiet on ten meters right now, but as cycle 22 picks up steam, the need for some sort of spectrum management will become more urgent. One of the biggest changes to the present structure made by Bob's proposal is the elimination of half of the AM window (29.000 to 29.200). If you have any thoughts on the matter, please send a note to Bob at PO Box 78, Marissa IL 62257, with a copy to Iowa Repeater Council president Dennis Crabb WB0GGI, 1306 4th Avenue North, Denison IA 51442.

Bird Books

TWO POPULAR BOOKS on commercial satellites have been updated. The second edition of ***The Hidden Signals on Satellite TV*** adds 60 pages of text and two new chapters covering Ku-band reception. The book is available from Universal Electronics, Inc., 4555 Groves Road, Suite 3, Columbus OH 43232. Weather-facsimile fans should pick up the new third edition of Dr. Ralph Taggart's ***The Weather Satellite Handbook***, now published in a plastic binder to make updates simple. This is about the best book going and covers everything you need to know about receiving WEFAX. You can get a copy right from Ralph—send $12.50 to Ralph's callbook address. Ralph has agreed to conduct a weather-satellite column in *73*; it'll be starting next month.

Radio Cops

A NEW VERSION of the Electronic Communication Privacy Act has been unanimously voted out of the House Judiciary Committee. The revised bill, HR-4952, clearly stipulates that it is *not* a crime to simply receive a signal, whether the reception was intentional or not. The language seems to be a little closer to the existing privacy statute which forbids divulging the content of a radio signal. There *are*, however, some pretty puerile items in the bill. Certain types of communications (including cellular telephones, encrypted services, and common-carrier transmissions) are considered "protected" under the bill since they are not designed to be accessible to the general public. HR-4952 spells out the fines and sentences to be imposed upon anyone who tunes in to this type of radio signal. It's easy to look at something like this and laugh. . . the whole idea is really ludicrous. *But*, there is an *enormous* amount of pressure from the communications industry, especially the cellular people, to get this bill pushed through Congress. There is a very real chance that they will succeed. Obviously, if the bill passes, there won't be radio police running around with DF gear—the provisions of the legislation would be extremely hard to enforce. Still, the idea that, for the first time, the government would tell us what we can and cannot listen to should be enough to get you to write your representatives in Washington. Put down the magazine and do it *right now*. It's been about two months since this story was written, and a lot can happen in two months. . . let's hope it's not too late.

Kiwi Flys By

73's own Kiwi correspondent, **Des Chapman ZL2VR**, traveled through scenic Hancock recently to visit the palatial editorial offices of *73*. Des (pronounced Dez) arrived as we were in the middle of an internal reshuffling of desks—in other words, the normally eighth-wonder-of-the-world-like editorial section looked as if an earthquake had just hit, with the epicenter being the desk of KW1O (who was conveniently out of town). We repaired to the Hancock Inn to wash away the dust of the road and get acquainted in person. Des is our kind of DXer, a man who would rather talk to someone on the air than "work" him. We learned much in a short time about New Zealand—not politics or the like, but more practical information like how to buy a round of beer ZL style (just say "It's my shout."). Des has been a faithful provider of ZL news for our *73* International section for a number of years, and it was a pleasure and an honor to meet him in person. Thanks, Des, for your fine work, and when you come this way again, remember that it's our shout.—*KA1MPL*.

Elmer Bank

TWO NEW BANKS have been opened by the **Westchester (NY) Emergency Communications Association**. The programs are designed to help newly licensed hams find their way around their new hobby. The Equipment Bank is a stockpile of surplus gear monitored by Bob Steinberg WA2KHR. Bob contacts new hams in the club to determine what they need to get on the air; when a need matches something in the bank, the equipment is loaned for 90 days. Once a station is set up, new amateurs can contact Adam Weiss WA1WMZ at the Elmer Bank to get paired with an experienced ham who gives the newcomer personal attention and aid. If you'd like more information about WECA and their banks, drop them a note at PO Box 131, North Tarrytown NY 10591.

Fake Out

DON'T BE SURPRISED if in October you hear enormous pileups on what seems to be a U.S. Extra-class license. From October 20th to the 25th, the **Radio Club Mar del Plata** will operate **AZ1D from Trinidad Island** during the ninth IARU Region II conference to be held in Buenos Aires. Trinidad Island is situated about 30 miles south of Bahia Blanca on the Argentine coast. On CW, look for AZ1D on 3.510, 7.005, 14.020, 21.020, and 28.020. On SSB, the operation will be around 3.690, 7.090, 14.200, 21.300, and 28.600. The group also plans to be active on six and two meters (50.110 and 146.52/144.30) and on OSCAR 10 (if it's working).

Time Tip

IF YOU'RE HAVING TROUBLE receiving WWV, you can get accurate time information by calling the National Bureau of Standards on the landline at (303)-499-7111. Don't forget that at 18 minutes past the hour, WWV transmits current and predicted propagation conditions.

I Like Eico

JOHN HODGE called to say that he loves his Eico three-band transceiver, and also that he had successfully tracked down Eico in Hampstead, New York. I had thought that Eico was belly up, but according to John that's not the case—in fact, he placed an order for several items he needed for his rig. Their address is 113 Fulton Avenue, Hampstead NY 11550, or you can call them at (516)-485-1331.

Deeply Asleep

OSCAR 10 IS IN DEEP DOO-DOO. The memory fault that crippled the satellite earlier this year has gotten worse, and attempts to write around the damaged areas have not been successful. Speaking with the *Westlink Report*, AMSAT president **Rip Riportella WA2LQQ** said that the engineering team working on the problem "had been looking for reasons to be optimistic [for the craft's recovery], but frankly had not found any in recent days." As reported last month, the newest Phase 3 satellite is on the ground, waiting for a launch opportunity on the European Space Agency's new Arienne-4 booster. ESA's space activities were squelched when an Arienne-2's third stage failed to ignite, causing the destruction of the booster and the $55 million Intelsat V satellite. Launches will resume as soon as the accident has been fully investigated—some sources fear a two- or three-year delay, although AMSAT is confident that Phase 3C will be launched in 1987. In the meantime, bird watchers will have at least one new spacecraft to play with, the Japanese-built JAS-1 scheduled for launch on July 31; rumors also abound concerning the imminent launch of two new circular-orbit Soviet satellites, RS-9 and RS-10.

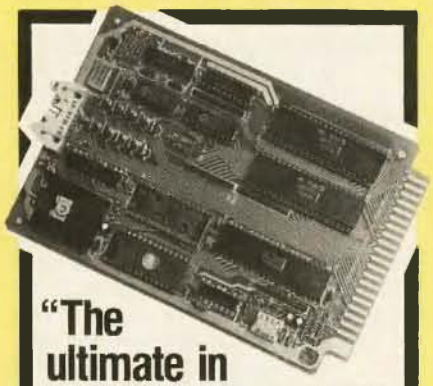
Check Writing

A FEW PEOPLE have been asking about the Reader Service cards that appear in each issue of *73*. Here's how they work: When you see an advertisement for a product that you would like to receive more information about, look in the ad for a small check mark followed by a number (it's usually close to the company's name). This is the number to circle on the Reader Service card. We have a pair of wonderful ladies here who'll send your name and address on a mailing label to the manufacturers you've selected. Pretty simple, eh? While you're in the filling-out mood, complete the Product Report Card and the Feedback survey and drop them in an envelope along with your QSL order and your check for $19.97 (for a one-year subscription); you could also toss in a letter to the editor, and get the maximum value from your 22-cent stamp.

Help

HELP WITH THIS MONTH'S QRX came from The *Westlink Report*, The *W5YI Report*, *220 Notes*, *Sweden Calling DXers*, and Rich Moseson N2BFG. Please send your news bits and pictures to *73* Magazine, 70 Rte. 202 N., Peterborough NH 03458, Attn. QRX.

DURA-FLEX™
shock mounts silence
spring-generated RF noise.



- **DURA-FLEX neoprene elastomer** significantly advances antenna shock absorption technology.
- **Eliminates RF noise** in duplex radio systems from metal-to-metal contact in conventional steel springs.
- **Drastically cuts whip vibration** which can damage or break antennas with steel springs on high-vibration vehicles.
- **Solid brass adaptors** molded into neoprene; braid totally isolated through center cavity.
- **Field-proven** against heat, cold, humidity and abrasion extremes.
- **Models** for roof, trunk or magnetic mounting. 2 meter, 220 MHz or UHF.

we design solutions.

"The ultimate in Touch-Tone control"

The ITC-32 Intelligent Touch-Tone Control Board is the only decoder with the power of a built-in microcomputer. That means maximized capabilities at a competitive price. Features include 28 remotely controllable outputs, sense and alarm inputs, and command acknowledgement in Morse code. Plus basic repeater and remote base control functions, built-in.

Strengthen the foundation of your Touch-Tone remote control system. Don't settle for a "dumb" decoder, when for just a little more you can have the power of ACC working for you!

To order, use MasterCard/Visa or send $275 plus $7.50 for UPS air shipping. California residents add sales tax. Specify a command code prefix (between 1 and 7 digits), and a callsign if for repeater use. To order the manual only, just send $10.00.

NEVER SAY DIE

from page 4

you have to do is create your job...defining it to fit your abilities. How? Well, if you do some homework...and presumably, if you really want to work for the firm, you must know something about it...if you find out some weaknesses the firm has...there may be a weakness you can solve for them.

Make sure of your facts, then go to the boss...not the personnel department...and show him (or her) how you will be able to help the firm to make more profits. Your salary will be unimportant if you can solve a problem for the boss. Make sure you're on firm ground with your recommendations.

You can find out a lot about a firm by reading the local papers...reading the trades... and then by getting to know some of the people working there and getting their support. They'll know where the problems are and what's been done so far to solve them. They'll know where you might fit in to make things better.

Once you're in and effective, you want to keep your eyes open for managerial opportunities. If you've been doing your homework...learning about management, advertising, finance, planning, computers, spreadsheets, writing, speaking, etc., your combination of management and technical skills will put you into a position to make real money. And management is where the money is.

If you prefer to be an entrepreneur, you still are going to need both management and technical skills. Indeed, 90% of small businesses fail in the first five years for a lack of management skills. Management is no more intuitive than engineering. Management takes learning and practice.

I've had a lot of hams write to me or approach me at hamfests and say they'd like to work for me. I can't think of any yet who came to me with a plan for making money for Wayne Green Enterprises. They've all had in mind making money for themselves and it really never occurred to them that if they make money for me, they'll make money, too.

When a prospective employee starts asking me about the benefits, I know he's thinking of vacation days, sick leave, and all those things that are going to cost me money without providing me with any benefits. What I want to know is what are the benefits I'll get by having this person working for me. Will he make *73* more fun to read and thus perhaps bring us more readers? Will he be able to help us put out better subscription solicitation letters and thus increase circulation? What are the benefits to *73*? I can't remember anyone ever giving this any thought when they were applying for work.

When you go for a new job, are you more interested in what you can do for the firm or in what kind of insurance plan they have for you? Do you worry about how often they review people for salary adjustments or how you can bring them more business? You know the answer...and I'll bet it's why you're not making nearly as much as you could be.

One of the most basic elements of salesmanship is pointing out the benefits of what you're selling. The most important product you have to sell in the whole world is yourself. So what are the benefits you provide? Once you start thinking this way you'll start seeing ways you can benefit your company more. You may see opportunities to learn more about something and help your company that way. If you think in terms of benefitting the company instead of benefitting yourself, you've made the first major step toward being a real success in life.

We have one of the best places in the world to work here at WGE ...great people...the most modern magazine publishing plant possible...enormous growth potential...good pay... one of the most beautiful parts of the country in which to work and live...a smoke-free environment...opportunities to learn and develop skills in current or new projects...yet even here we have some people who are wasting their lives by not taking advantage of what's available. How many of the opportunities available to you where you're working are you really using?

I had one chap we hired to start a new business for WGE. He was hired at a very good salary, we bought him a home, gave him assistants and a car. Despite all urging, he spent months planning and got nothing of benefit done. When our patience finally ran out and he was replaced by a new one-man department which promptly got the business going, he was furious with me...instead of with himself.

Many of our activities in amateur radio provide us with the expertise to do commercial work. Hams who get into building and repairing of ham gear are naturals for two-way businesses. Hams who get into computer repairs are desperately needed by computer repair outfits. I've recently mentioned the potential in home and business security firms.

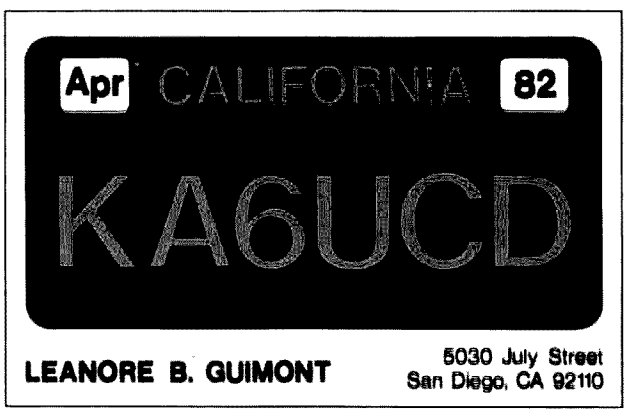
Many ham developments can be escalated into commercial products for the entrepreneurially minded. A recent application of slow scan turned up at the Chicago Consumer Electronics Show ...a unit with a camera and monitor which sends pictures over telephone lines. How long before we start seeing commercial packet-radio applications?

Not a few hams have escalated their interest in OSCAR into home satellite sales. That business is in a turmoil right now due to the recent scrambling of signals, but I suspect we'll see some creative solutions to that...probably from a ham.

Maybe you should flag this part of my editorial and re-read it again in a few weeks.

THE AGONY OF SLOW SCAN

Slow-scan television looks like it sure should be fun. Imagine, being able to see snapshots of the chap you're contacting...a picture of his shack...his house. Wowl



Well, of course there are some downside aspects of slow scan, but there are a lot of wows too. There seem to be enough fun aspects to SSTV to keep the 14.230–40 channel fairly active every day.

I got interested in slow scan in its early days, about 15 years ago. I seem to enjoy pioneering on the ham bands...getting very active on NBFM in 1946, RTTY in 1949, repeaters in 1952, and so on. The camera and monitor for slow scan aren't exactly for paupers, so it isn't a branch of the hobby one gets into casually.

With the camera and a monitor I was in business. Of course I already had a fairly substantial 20m station...as key an element in making dependable SSTV contacts as in any other. I recommend the usual sideband transceiver, kilowatt amplifier, and three-element (or larger) beam up 75 feet on a tower. The usual for DXing or contests.

I set up a restaurant menu board on an easel so I could focus the camera on it. On this I put my call, with a place for calling CQ or confirming the call of the chap I was working. When I'd make a contact, I'd get out the call letters of the chap I was working to snap on the board. That was my QSL.

I also set up a small 35mm projector and a video converter unit...a small mirror with a frosted screen for projecting slides so you can put them on video tape. I'd swing my camera from the menu board to me sitting at the operating desk to the converter for slides of the shack, the house, my

QSL OF THE MONTH

To enter your QSL, mail it in an envelope to *73*, WGE Center, 70 Rte. 202 N., Peterborough NH 03458, Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

daughter Sage, and so on. I worked up quite a series.

Unless you're set up for color SSTV, you'll do better to buy some positive black and white film and shoot your material in black and white. Color slides don't do well when sent in black and white. The gray scale is screwed up.

Being a recognized amateur radio fanatic, I naturally went on to get a second camera so I didn't have to get up and swing it between frames.

There are two major problems with slow scan. One is the amount of thought and work it takes to come up with an interesting program to send. Remember, you can send your program to each chap you work only once. The next time he's not going to be interested in seeing the same old stuff again. So what do you do for an encore? Along about the third contact with a station you're finding the pressure for new programs getting to you. You're running out of ideas... and then soon you're running out of people who will call you. Next you run out of hams who will even admit they can hear you.

The second misery is the other chap's programming. How many times do you want to sit and watch pictures of his kids, his dog with earphones on (DX hound... get it?), his messy shack, and, perhaps worst, fat, ugly him? It's fortunate there are so many SSTV-ers, so for a few weeks you have a good selection of chaps to contact. But then it begins to thin out... the same stations... the same pictures as you tune up and down the band. Hmmm, Playboy centerfolds, so that has to be that YV5. Old girlfriends and pinups... that's the W4 in Miami.

I once ran a slow-scan program contest and got quite a number of creative programs submitted on cassettes. I put the best of them together on one tape and made it available. It wasn't exactly a profit center for the magazine, but it did pay for the trouble... and I think it helped give slow scanners some desperately needed ideas. With some urging I might try another slow-scan program contest... any enthusiasm? It'll be interesting to see how much change we've had in the ten years or so since the last contest.

With over a hundred countries available on slow scan, the program problem is not an immediate one. Indeed, if you stick to DXing and don't play around with lengthy programs, it isn't a problem at all. That's like beefing about the lack of discussion topics brought up during contest or DX-pedition contacts.

I expect there are many readers who are interested in knowing what's going on with color slow scan... with high-definition slow scan. Let's see some articles bringing us up to date on the slow-scan frontiers.

HOW TO BE A MISERABLE ROTTEN FAILURE

Surrounded, as we are, on every side by miserable rotten failures, who needs a lecture on how to achieve this dubious undistinction? Yet, at any time in life, no matter how misspent... even a life dedicated to the pursuit of the religious ecstacy of working DX, probably second only in galactic importance to a lifetime spent memorizing baseball statistics ...it is possible to firmly grasp one's bootstraps, pull one's self out of the muck of life, and join the select fleet few who are successful in more than their own eyes.

Without getting into hair-splitting definitions of success and failure, let's use the usual yardstick... dollars. Dollars you control, whether you own them or not. This will get us away from personal judgements... such as my feeling that anyone who really cares whether a *73* subscription costs $20, $25, or even $30 a year can hardly be classed as a success. Is the magazine fun to read? Okay, I want it, here's my credit card.

If you want to drive a crummy car... fine... but if you *have* to, that's something else. That's avoidable.

Okay, let's get right to the heart of what makes someone successful... other than luck. And even luck can be loaded. When people tell me how lucky they think I am, I say sure, and the harder I work, the luckier I get. We sure have a screwed-up language... and some of the screw-ups can give us major problems. Like that term "work." We use that to describe what we do to earn money, using the same term whether we're enjoying what we do or hating every minute of it.

Sure, we do have words to differentiate, but we're lazy about our language... to some degree. But even William Safire isn't likely to say he's going to drudgery. For those of you who don't read much, Safire writes about words.

Well, enough of that... now, let's take a look at what separates the sheep from the goats... the men from the boys (of all ages). We can even get more fundamental than that. What separates man from all other life on Earth? How did man come to win out? We certainly aren't the strongest animal. A short listen on two meters in Los Angeles should convince even the most stubborn that we're surely not the smartest animal. So how'd we win?

We won out by wearing 'em down. There are many animals much faster than man, yet we're able to catch all of 'em in the long run. Man can outrun a horse, an antelope, and even a cheeta. 26-mile races are popular now... heck, Southwestern Indians used to have 100-mile footraces. We don't even make much of a deal of it when someone walks 3,000 miles across the country.

Fine, he's talking about winning marathons and I work in an accounting office... or sell shoes. The formula for success... the formula for failure... they're the same, whether you're selling shoes or winning a marathon. Most of us go through life, making our choices from what is handed us and griping about it. Few even bother to read books on how to be successful. But how can you expect to hit success if you don't even aim at it? Perhaps you've noticed that relatively few people really succeed.

Heck, everyone can't be a success, right? I'm not so sure. I do know that the more people who are successful, the more successful the country will be. For many years Americans made double and triple as much as people in most other countries. No more. Just as Great Britain had the world in its grasp a hundred years ago and now is heading rapidly toward being one of the poorest countries in Europe, so we're seeing America slipping from its pinnacle of power and success, which peaked in the 50s.

Your personal success or failure depends more than anything else on your persistence. Your failure to persist... plus that of 240 million other unpersistent Americans... adds up to America losing out to Japan in one industry after another. The fact that the Japanese are able to come to America, set up factories, and beat the heck out of American-run factories making the same products... beat 'em in efficiency, productivity, and quality... can't be ignored.

How can we apply this concept to our own lives? What can we do differently so we can start being winners? Let's take the accountant as an example. The choice for him (or her) is to go to work every day, do things the same way as he's always done, go home, watch television or go to dinner and a movie... and back to work again the next day. He might even substitute a couple hours on a 75m net for some television... or a couple nights a week bowling.

The persistent accountant is going to be looking for accounting courses he can take to learn some specialties. He'll be reading the latest books and accounting magazines. He'll be working his way into the business management of his firm. He'll be watching for ideas that he can use with his clients to save or make them money.

The enthusiastic accountant will be checking out many computerized accounting systems to see which is best for his clients ...which is easiest for them to use... which can save them more money. He'll set it up and train them to use it. Different types of businesses call for different computer systems.

With some education in financing, he might help his clients get money—arrange bank loans, set up stock and bond deals, or find investment groups and put 'em together. Soon our accountant is attractive as a chief financial officer for a corporation... and from there, if he learns more about handling people and the technology of his business, to president.

Our ancestors had to outlast antelopes to get a good dinner. Today we get our dinners with education instead of running. Running we do just to keep our bodies in shape so we can enjoy life... but it's still the long haul which wins.

You know, if we set good examples for our kids... if we show them with our own lives that persistence wins... I'll bet we'd have far fewer kids griping about how stupid it is to learn the code to get a ham license. Think about it... what have you done to set a good example for your kids? Are you teaching them with a six-pack and a bag of potato chips as you watch sitcoms... or by taking night and mail-order courses?

If you persist in learning more and more about what you're doing, you'll be surprised at how quickly you sail far beyond everyone else around you. When I started *Byte* magazine in 1975, I didn't

Continued on page 82

LETTERS

HELL NO

All my life I have had a problem learning languages. I just can't seem to translate another mode of communication into good old English. This disability carried over into ham radio with having to learn the code.

The ARRL not only avidly adheres to the code requirement, but they demand you learn the code and take the same form of code test that "they took." For four years I struggled to pass the 13-wpm code exam. I bought tapes, took courses, got on the Novice bands and worked thousands of QSOs, but I still couldn't pass the 13-wpm test...that is until last night when I breezed through the 20-wpm test!

About two weeks ago, while practicing code with my C-64, I discovered that if I speeded up the characters to 20 or 25 wpm (but with 13-wpm spacing) I went from 50% copy to 100% copy. Delighted with this discovery, I called one of our ARRL-sponsored volunteer examiners and asked if I could take the test with 20-wpm characters and 13-wpm spacing. The answer I received left me with the impression that our ARRL VE could not walk and chew gum at the same time. He did mumble that I might try clearing it through the ARRL VEC in Newington.

I immediately got on the phone to ARRL HQ and asked to speak with the VEC. His answer was a flat NO. He went on to mumble something about someone called Farnsworth and the Farnsworth Method, but when queried about what this mystical method was he didn't know. When I pointed out that the FCC rules did not prohibit the test in this manner, his response was "well that's the way I took the test," and I should do likewise. I asked who his boss was and could I speak to him. I was told that he was the boss and that was that. I then asked who he took his instructions from at the FCC, and he finally responded Larry Wykard.

I called Larry Wykard at the FCC and asked him if the FCC had any objections to my taking the test with the faster character speed. I was told that as long as it came out to 13-wpm, he didn't care how fast the character speed was.

I then approached our local ARRL VE armed with the OK from the FCC. Not only was I rebuked severely but I was also told to take the exam as the ARRL provided it or get out. He refused to discuss the matter and said he took his orders from the ARRL and didn't care what the FCC said.

I took the exam as provided by the ARRL and flat flunked it. I couldn't copy 40% with the slow character speed.

I then learned that an outfit called W5YI could also give exams...and best of all there was a scheduled exam in two weeks in the next town. When I told the W5YI VE of my problem with the slow character speed, his response was, "What speed do you want the characters sent at?" No hassle, no argument, no problem. I went to the W5YI exam and breezed through the 20-wpm test. It took me about 20 seconds to fill out the answer sheet. The attitude of the W5YI VEs was more than cordial; they went out of their way to help those of us taking the exams. They gave us all the practice code we wanted and waited until all were ready for the test before beginning. They were the most polite and helpful group I have ever run into in ham radio.

About a month ago (before I knew about the W5YI VE program) the ARRL sent me their letter urging me to renew my membership. I was somewhat disgusted with the whole situation and the 13-wpm code test. I was seriously considering quitting ham radio, and I tossed the letter aside. Today I frantically searched for it, found it, and answered "HELL NO."

Jim Shook N4KIM/AG
Ocala FL

Jim, you can't blame the folks at the League...they can't help it if they're stuck with a sluggish bureaucracy. Just about every decision made at the ARRL is made by some sort of committee—a committee which then presents its decision to a board for a vote. Of course, the board needs time to weigh all of the consequences, and, after all, there's no need to just rush into things, right?

Groups like the W5YI VEC can be very accommodating since they're in business to help people get licenses, not to maintain a power structure.

Since you mentioned it, I'd like to point out that the best way to learn code is to start right out at the speed you want to use. If you want to copy 20 wpm, then learn what characters sound like at 20 wpm. That way your brain hears the sound and immediately associates it with a character without any further processing.—KW1O.

WHY THE WAIT?

"Please allow 6–8 weeks for delivery" and the paradoxical parenthetical expression "(We're computerized for speed)" somehow seem grossly inconsistent with your 12-page subscription mailing. I had the card filled out—which incidentally didn't fit the envelope provided—a check enclosed, and the envelope sealed, but became increasingly uneasy about the inconsistency, to me, between the handling of a new subscription and what you "say," and how you "say" it, in 12 pages. I read it all and don't believe I've ever read that much from anyone else who wanted something from me.

Why do most suppliers of mail-order items want 4–6 weeks, and you want 6–8 weeks, to get something delivered? Or to change a subscription address?

I'm sitting on my sealed subscription envelope for a while.

Preston B. Tack N6MXJ
Desert Hot Spring CA

Most mail-order houses will sell things to anyone who sends them money. Here at 73, we're a bit more discriminating—after all, we can't let just anybody read our magazine! Once we receive your application for subscription, it takes about 6 weeks to check you out with the FCC, your local radio club, and your third-grade teacher. (If you haven't heard from us in 6 weeks, start looking over your shoulder.)

As they say, many call, but few are chosen.—KW1O.

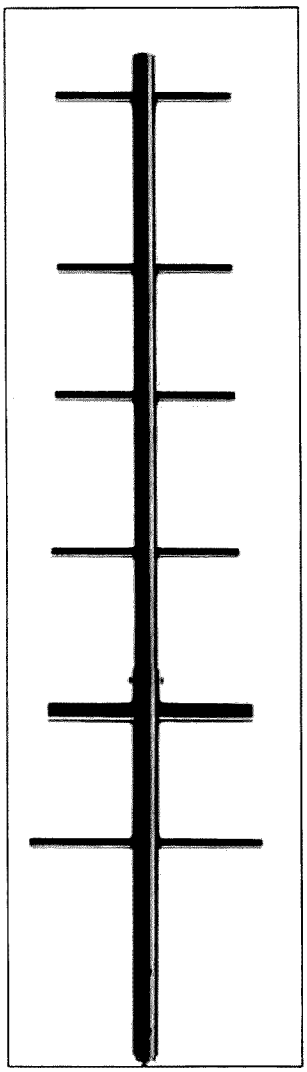
PRICE OF HAM

As a non-ham, I'd like to complain about the ticket prices charged at hamfests. It seems to me that the money should be used to cover a club's expenses in presenting the event as well as to make money for other club functions. However, much of this money is used to buy the prizes offered for the hamfest.

From what I've seen, the people winning the main prizes are those that already have a similar piece of equipment, and rather than selling the old set and keeping the new one, they try to sell the set they won.

Another thing about hamfests that bothers me is when a club states that if a non-ham's ticket is drawn, the club will not give him a transmitter if that is the prize. One club said it is their policy not to allow transmitters to be given to unlicensed people. I can think of lots of instances where a non-ham might want to do something with a transmitting rig, such as keep it for when he does get a license, use it as a receiver only, an XYL could give it to her husband, it could be donated to a club, and so forth. If I get a ticket to a hamfest with such a rule, I just put someone else's name on the ticket.

Another point I'd like to bring up is the cost of getting into a hamfest just to look at most of the same things I saw at the last hamfest. The charges for some hamfests to set up a table to sell are also excessive. Why can't they have a $1 or $2 admission and another $1 or $2 for setting up? I have gone to record conventions and gun shows that were extremely large, yet I was charged $2 at most for admission.



Monty Meier
Apple Creek OH

The most I've paid is $9, which I thought was a real rip-off. Most of the shows I've seen have been worth between $3 and $5...the value is directly related to the size of the flea market.

Restricting certain prizes to licensed amateurs is just ludicrous. A prize is a prize, guys. Besides, what better incentive is there to get a license than to be given a shiny new transceiver? If a non-ham wins, instead of making him feel like dirt, the club should do all it can to help the fellow get his ticket.

Do you know what the real problem is, Monty? It's that hams take their hobby too damn seriously. They're always worrying about little nit-picking rules and feeling self-important about their "hard-earned" licenses—it's no wonder that young people are turned off by such a pompous bunch. I guess that after 20 or 30 years, one forgets how much fun ham radio used to be.—KW1O.

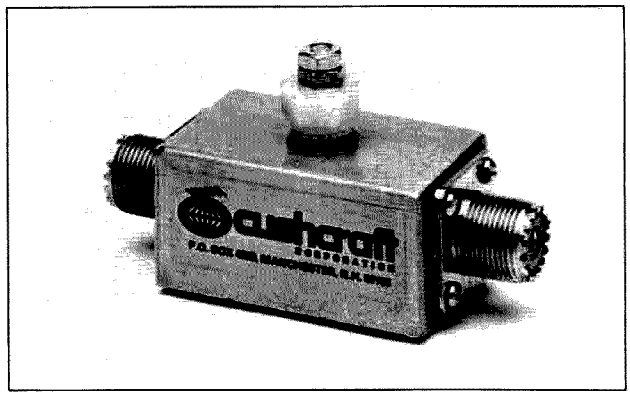
NEW PRODUCTS

Larsen's new 900-MHz yagi.

LARSEN YAGIS

Larsen Electronics has announced the YA5 series of yagi antennas for use in the 806–860-MHz range. The YA5-806 is designed for cellular-radio operation, while the YA5-900 can be used on the amateur 900-MHz band.

The antennas feature all-weather construction: The coax is terminated inside the yagi, and a black weather-resistant coating is applied at the factory. The antennas have a 10-dBd gain, a horizontal beamwidth of 45 degrees, and can handle up to 300 Watts.



For more information, please contact *Larsen Electronics, PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 153.

NEL-TECH DIGITAL VOICE KEYER

Nel-Tech Labs' DVK-100 is a microprocessor-controlled digital voice storage and announcement system. The DVK-100 is configured with 32 seconds of voice memory divided into four messages of 16, 8, 4, and 4 seconds. Other features include a built-in selectable audio compressor, an end-of-transmission tone, and an amplified local monitor.

The DVK-100 is compatible with all transceivers. Transmitter keying is switch-selectable between positive and negative keying voltage.

For complete details, write or call *Nel-Tech Labs, Inc., 28 Devonshire Lane, Londonderry, NH 03053; (603)-434-8234.* Reader Service number 155.

Cushcraft's new lightning arrestor.

C. ITOH COLOR DMP

C. Itoh Digital Products has introduced a seven-color version of their high-speed 80-column ProWriter C-310 and wide-carriage C-315 dot-matrix printers. The DMPs can turn out color graphics with a density of 240 x 216 dots per inch and support popular software packages such as Lotus 1-2-3, Symphony, GEM, and PC-Paint. Print speeds are 300 cps in draft mode, 50 cps in correspondence mode, and 33 cps in letter-quality mode.

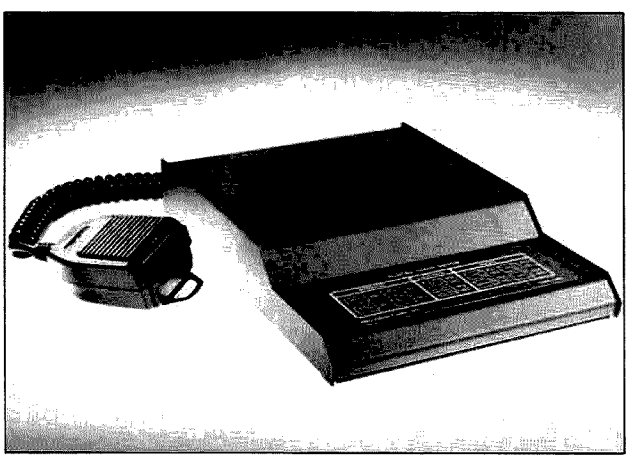
The C-310 ($739) and C-315 ($909) come with a variety of resident character fonts and both an 8-bit parallel and an RS-232 serial interface.

For complete information, contact *C. Itoh Digital Products, Inc., 19750 South Vermont Ave., Suite 220, Torrance CA 90502.* Reader Service number 162.

CUSHCRAFT ARRESTORS

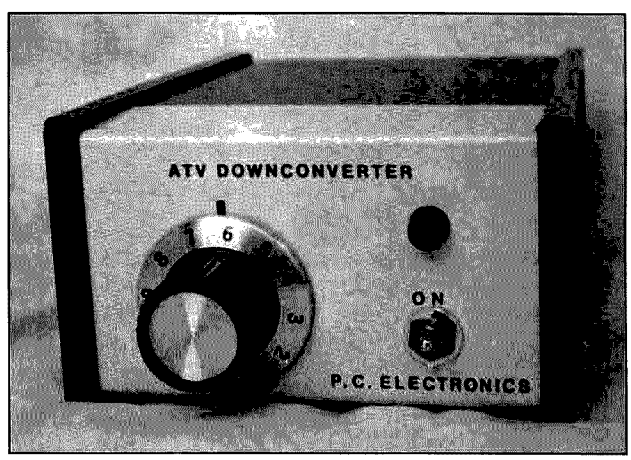
Four new coaxial lightning arrestors are available from Cushcraft Corporation. The models offer a choice of power (200 or 2,000 Watts) and connector style (UHF or type N). Replacement cartridges are available.

For more information on these and other Cushcraft products, please contact *Cushcraft Corporation, PO Box 4680, Manchester NH 03108; (603)-627-7877.* Reader Service number 158.



J.S. TECHNOLOGY SINAOAPTOR

J.S. Technology's model SAI-01 Sinadaptor is a pocket-sized unit which turns any VOM into a Sinad meter. The only constraints are that the VOM or VTVM must have a sensitivity of 2.5 V ac or better, and that the meter must have a scale marked in dBs.



For complete information, contact *J.S. Technology, Inc., 39 Main Street, Scottsville NY 14546; (716)-889-3048.* Reader Service number 156.

GaAsFET ATV DOWNCONVERTER

P.C. Electronics has added a GaAsFET ATV downconverter for

The DVK-100 digital voice storage and announcement system.

900-MHz ATV downconverter available from P.C. Electronics.

the new 900-MHz band to their *line of amateur* television products. A dual-gate GaAsFET is used in both the rf preamp and the mixer stage for low noise and wide dynamic range. Total conversion gain is about 25 dB.

Two models are available. The TVC-9G ($109) comes installed in a cabinet and is ready to plug into an antenna and a television set. The TVC-9 ($69) is for those who want to package their own system (such as a mast mount).

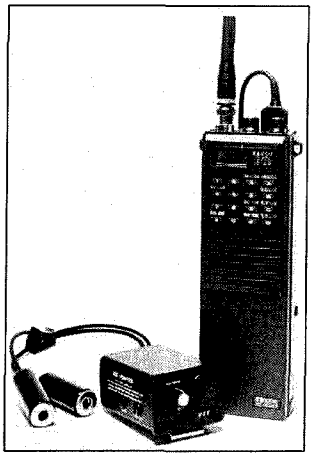
For more information on ATV products, please contact *P.C. Electronics, 2522 Paxson Lane, Arcadia CA 91006; (818)-447-4565.* Reader Service number 160.

ICOM IC-A2 ACCESSORIES

Three new accessories are available for ICOM's IC-A2 hand-held airband transceiver.

The IC-CM28 NiCd battery charger ($19.95) operates from any 28-V-dc power source for use in flight or on the ground. (A 12-V cigarette-lighter cord, the IC-CM1, is available for $14.50.)

An alkaline battery case, the IC-CM12 ($24.95), holds ten AA cells for an output of 5 Watts from the IC-A2.



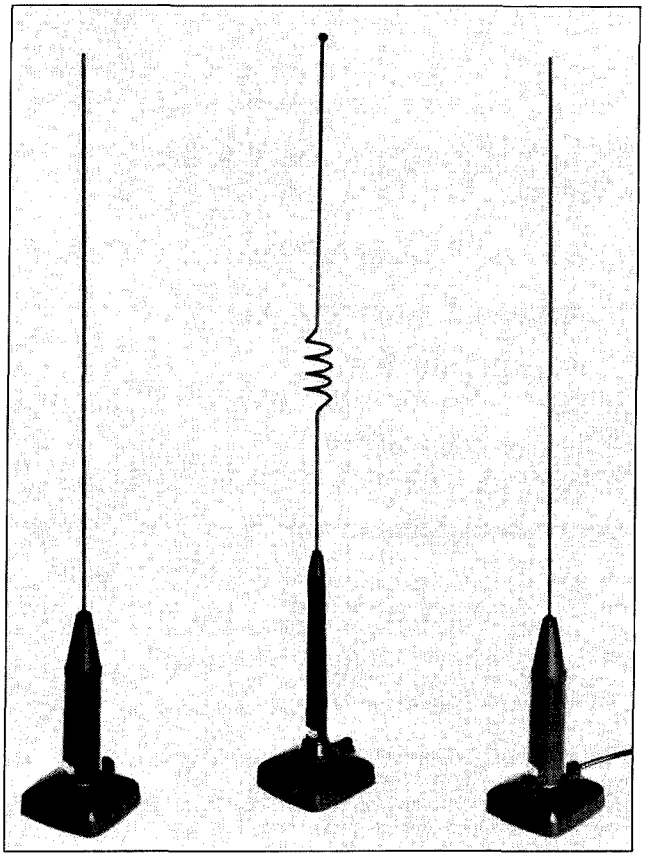
Hands-free VOX operation is possible with the addition of the David Clark Company DC VOX unit ($199.95). The VOX interface is designed to plug directly into a DCCI aviation headset, and can be adapted for use with nearly any standard headset.

For more information on the IC-A2 and its accessories, contact *ICOM America, Inc., PO Box C-90029, Bellevue WA 98009-9029.*

PALOMAR TUNER TUNER

Palomar Engineers has announced the Tuner Tuner™, a device which connects between the transceiver and antenna. A built-in 50-Ohm noise bridge gives an audible null in the receiver when the antenna-matching unit is adjusted properly, eliminating the *need to* transmit into a high vswr while tweaking the antenna tuner.

The Tuner Tuner (model PT-340) retails for $99.55 plus $4 shipping and handling—for more information, contact *Palomar Engineers, Box 455, Escondido CA 92025; (619)-747-3343.* Reader Service number 157.

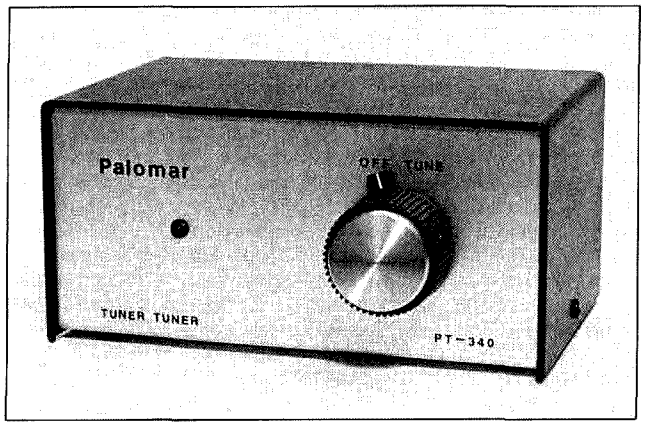


Accessories for ICOM's IC-A2 airband hand-held.

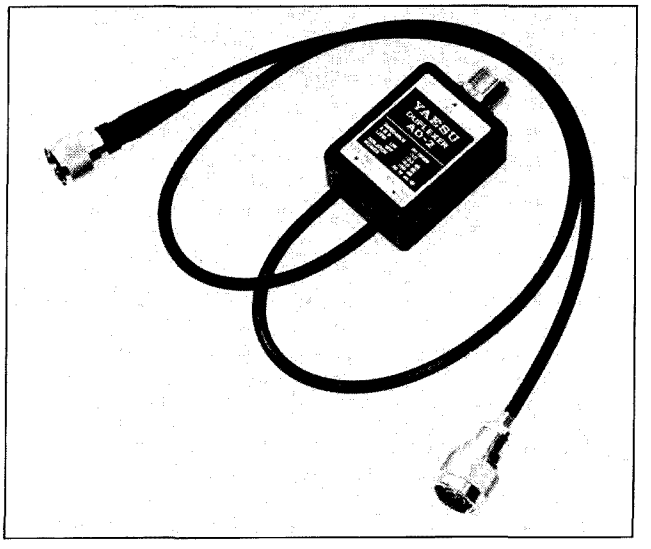
YAESU AD-2 DUPLEXER

Yaesu has announced the new AD-2 Duplexer for the FT-2700RH and FT-726R transceivers. The AD-2 provides for semi- or full-duplex crossband operation with a single 2m/70-cm antenna. Band-to-band isolation is 50 dB; insertion loss is less than 0.3 dB at VHF and less than 0.5 dB at UHF. The AD-2 can handle 50 Watts of rf.

For further details, please write *Yaesu Electronics Corporation, PO Box 49, Paramount CA 90723.* Reader Service number 161.



Black Stallion CB antennas from The Antenna Specialists.



BLACK STALLION CB WHIPS

The Antenna Specialists Company has come up with a new line of mobile CB antennas. Three configurations provide for just about any mounting requirement, including trunk-lip, trunk-mount, and mag-mount. The model M-900 is designed to look like an elevated-feed cellular antenna. All three versions are coated in black Teflon™.

For more details, write *The Antenna Specialists Company, Marketing Dept., PO Box 12370, Cleveland OH 44112-0370.* Reader Service number 159.

Palomar Engineering's Tuner Tuner.

FT-2700RH/FT-726R duplexer allows use of single VHF/UHF antenna.

ICOM IC-1271A 23-Cm Multimode

by Peter H. Putman KT2B

ICOM America, Inc.
2380-116th Avenue NE
Bellevue WA 98004
Price class: $950

Photo A. The ICOM IC-1271A 23-cm multimode transceiver.

Can it be? Have I actually found a UHF multimode radio I really like? Well, I'm not that hard to please. I do enjoy using multimodes, especially when operating portable. It's just that they usually don't compare to a good quality HF radio with transverter ahead of it.

But one thing that multimodes have never lacked is operating ease. Despite their receiver limitations, it's all in one box! That's hard to beat for convenience. And amazingly enough we may be closer to an 80-meter-through-70-cm multimode than we think! The Japanese are moving at such a rapid rate in this area that it was only logical that we'd see a multimode for 23 centimeters before long.

Features

ICOM is the first to break this ground with their IC-1271A transceiver. Designed as a companion to their low-band equipment and IC-271/471 series, it covers 1240–1300 MHz. For example, this is the first unit I've used on 23 cm with VOX, adjustable agc, and a noise blanker (somewhat useless and a real oddity!). I can write up to 32 independent memories into the unit and scan them, or employ two vfo's independently or split as needed. And, I have my choice of CW, USB, LSB, FM, and even ATV modes, all with a GaAsFET front end and 10 Watts of rf output!

Well, almost. The particular unit I tested measured under 10 Watts out. And the GaAsFET front end leaves something to be desired. And the ATV mode is an option. And who uses split vfo's up here, anyway?

Well, on to the nuts and bolts: Those of you who read the June IC-471A vs. TS-811A comparison will find similarities in the front-panel layout of the IC-1271A. As mentioned earlier, VOX, AGC, NB, and MODE controls are identical. A noise blanker at 1296 MHz is almost unnecessary, since all noise generated here comes from the front end, not the atmosphere. The agc is okay to have, but I doubt you'll ever change the setting. VOX is a real strange thing to use up here but fun to play with. You will need it to operate CW, however.

As in all ICOM models, the output power is continously adjustable, a nice feature I wish other manufacturers would adopt. On this particular unit, I connected a Bird Thruline section directly to the type-N output connector and a Bird 25-Watt Termaline to the other end. With 14.0 volts dc measured at the radio, I saw 8 Watts of rf output at 1290 MHz. A Bird 25K slug was used (25 W, 1.1–1.8 GHz). In the low-power position, I measured about 1.5 Watts using the same setup. Both measurements were made in CW and FM modes. Because I was unable to locate a spectrum analyzer that resolved frequencies greater than 1200 MHz, I skipped the output waveform tests and will have to take ICOM's word for their spurious emission suppression claims (better than −50 dB).

Let's get back to the controls. A separate TRANSMIT switch is available, which is a real plus when tuning up the typical 23-cm cavity amplifier. You can also enable the transmitter from the 24-pin molex jack on the rear panel, or in CW with the VOX on. The RF GAIN control functions like all other RF GAIN controls on ICOM multimodes, but you'll never turn it down on 23 cm! Multi-speed tuning rates are also available for the vfo knob, which are 25 kHz/1 kHz in FM, and 1 kHz/100 Hz in SSB/CW mode.

The memory functions are useful. You can memorize the frequency as well as the mode. Then, you can employ the MODE-S switch to scan through only those memories that contain your selected operating mode. Dual vfo's are available, and you can lock the front-panel vfo frequency while dialing through the memories and vice versa. In addition, if repeater operation is contemplated, offsets can be custom written. If desired, an optional UT-15 tone synthesizer can be installed for CTCSS operation.

Other options include an internal switching supply (IC-PS25), speech synthesizer unit (IC-EX310), computer interface (IC-EX309), and ATV interface unit (TV-1200). The latter requires only a VCR and camera on transmit, and television on receive for full wide-band color operation.

The balance of controls includes SQUELCH, although most of the signals worked on SSB/CW are so weak they won't break it, and METER, which switches between an FM discriminator mode and conventional S-meter mode as required. CW DELAY, VOX, and CW MONITOR controls are accessible through the top cover as in other ICOM models. A separate external speaker jack is available on the rear panel if needed. Other rear-panel connections include EXT SPEAKER, INTERFACE (for the EX309), DC POWER, ANTENNA, the same 24-pin molex ACCESSORY jack as on other ICOMs, and finally the TV IF INPUT and TV IF OUTPUT jacks for the TV-1200 accessory. As usual, ICOM includes a very detailed, well-written owner's manual and schematic with the unit.

I assume ICOM put these options into this

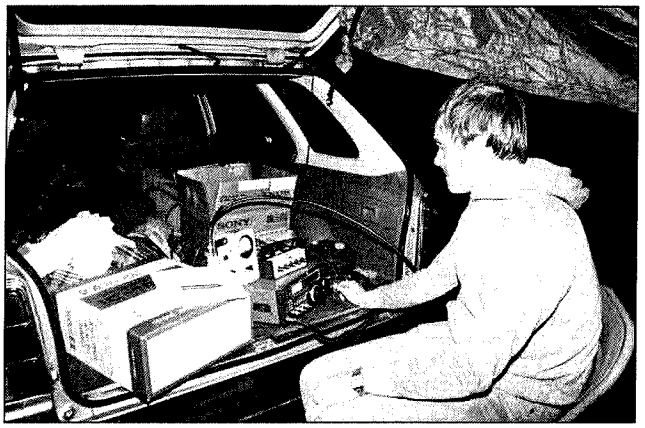


Photo B. KT2B putting the 1271A through its paces in the 1296 Sprint last May. Neither rain, nor snow. . . .

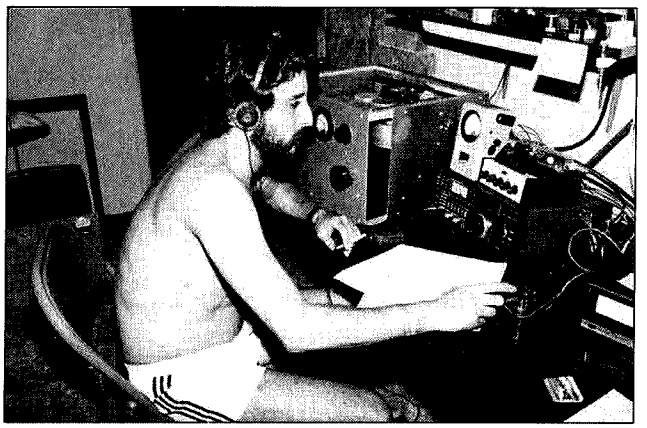

Photo C. WB2WIK using the 1271A during the VHF QSO Party last June. Note the 150-Watt home-brew cavity amplifier to the left.

radio because amateurs in Japan are already busy using these modes. On the other hand, the bulk of 23-cm activity in the United States right now is weak-signal SSB or CW, with a limited amount of FM, ATV, and satellite operation. The vast majority of U.S. owners may never use most of these controls. This could change if Novices gain 1240-MHz privileges, except that the radio runs 5 more Watts than Novices would be allowed to use. Perhaps ICOM will make a modified version of this radio if that happens.

On the Air

It seems that whenever there's a severe drought, all I have to do is decide to operate 432 or 1296 portable from a mountaintop and it rains cats and dogs (Photo B). WB2WIK and I ran the 1296 Sprint from atop Sunrise Mountain in northwestern New Jersey (grid square FN21). We were caught in a large moisture cloud shortly after setting up. The effect of operating into dense clouds at this frequency is well known. Using the unit barefoot, we worked ten stations in four grids, one of which was over 100 miles away in Atlantic City. Our antenna was the F9FT 55-element yagi on 30′ of mast from about 1600′ elevation. With a 13.8-volt battery we measured only 8 Watts output. In this operation, with the high-gain antenna, the receiver gave a good accounting of itself.

I had hoped to run some tests on 23-cm FM from the car, but the companion IC-120 shipped with the review unit had a defective front end and had to be returned to the factory, so my evaluation of the FM performance on the air was limited to using a transverter in the FM mode with my TS-430S. The quality of received audio was good, with crisp response as evaluated on the workbench. Again, the displayed frequency didn't agree with what I measured and was off by about +3 kHz. Signal strength for 20 dB of quieting was in excess of ICOM's claimed spec of 0.32 uV and closer to a microvolt.

Our luck was better during the June VHF QSO Party. Received reports indicated clean audio on SSB and no detectable chirp on CW. The PLL system is stable but not very accurate. When the display indicated we were operating on 1296.090 MHz, the measured frequency was actually 1296.093. In my opinion, this is acceptable at 23 cm since virtually all equipment in use here is off frequency by a few kHz as well. It won't be a problem on FM, as you'll see the presence of a carrier on the signal-strength meter. But you might go nuts looking for a weak SSB signal unless you use the RIT (good for plus or minus 2.5 kHz) or tune the vfo around a bit. Rf output is fairly stable across the range of 1240–1300 MHz, falling to 6 Watts at 1240 MHz.

"It seems that whenever there's a severe drought, all I have to do is decide to operate 432 or 1296 portable from a mountaintop and it rains cats and dogs."

The receiver utilizes a MGF1202 GaAsFET, and ICOM claims sensitivity in the SSB mode to be less than 0.16 uV for 10 dB S+N/N. I'll dispute that, as my SSB Electronics transverter is rated about the same but really does meet the specification. The ICOM appears to be more in the range of .7–.85 uV for 10 dB S+N/N. In fact, it took a really strong local signal which was line-of-sight running 100 Watts to make the S-meter pin hard. As in the case of the IC-471A, the 1271A meets and exceeds its claimed selectivity specs of better than 2.4 kHz at −6 dB in SSB/CW and better than 15 kHz at −6 dB in FM mode.

The radio really needs a preamp for serious weak-signal work. ICOM advises that a mast-mount preamp is available for the IC-1271A, although there isn't much mention of it in the owner's manual. My suggestion would be to employ either an internally mounted unit or a good rf/dc switched preamp, such as the SSB Electronics units. If you choose the ICOM version, it mounts at the mast and the coax feedline multiplexes rf and dc to run the preamp, actuated by the front-panel PREAMP switch.

In our contest operation, we employed an outboard GaAsFET to improve sensitivity. It made a big difference! With it, we worked 18 stations in 9 grid squares, the furthest of which was over 200 miles away. A 3CX100 cavity amplifier was also used, running about 130 Watts to 4 x 23-element Tonna yagis. Having the memory and scan functions is a bonus during contests, since you never can be sure where someone will pop up on the band during a schedule. Some stations who tried to work us were as far as 6 to 10 kHz off the agreed upon frequency!

Conclusion

If you like to run multimodes, the IC-1271A will be a nice addition to your shack for 23-cm operation provided you: (1) use a good-quality external GaAsFET preamplifier, (2) employ low-loss feedline and a high-gain antenna, and (3) have about $900 to spend. Whoa! $900? Yep, every penny of it. This is not a cheap radio by any means, and there's no doubt you can buy a good transverter for half that which will run rings around the IC-1271A. That's also a lot of money for a band that most people use only six times a year during contests.

The key here is activity. Should Novices gain 23-cm privileges and should the price of this unit drop to a more reasonable level (say, 500–600 dollars), ICOM will be sitting in the catbird seat with the 1271A, and it might just open up the band to more users, especially those interested in fast-scan color ATV operation. Although 23-cm repeaters aren't practical for wide coverage in hilly areas, I could see Novices using community repeaters with these units for FM and packet, with occasional forays into the weak-signal modes. But it's great for mountaintop and portable operation, as the 1271A weighs only 14 pounds.

And to think a transceiver like this was just a pipe dream five years ago.■

Heath HO-5404 Station Monitor

by Marc Stern N1BLH

Heath Company
Dept. 011-442
Benton Harbor MI 49022
Price class: $250

How many times have you heard a signal on 20 meters that's so broad and splatters so much that you just had to see it for yourself and, maybe, tell the other operator about it? With the congestion on HF today, the chances are pretty good that you've run into this situation at least once an operating session.

The next question that will probably arise, if you're serious about it, is: "How do I go about it?" If you can afford it, you might consider tying up a lab-grade oscilloscope at a slow sweep speed and a lower frequency response level. But there are few operators who can afford this luxury, especially if the scope is used for other things. The solution, then, is a station monitor, which also can double as a minimal level oscilloscope.

Usually inexpensive enough to be dedicated to monitoring station activity alone—$250—most station monitors add to their utility by offering pan-adapter modules so they will also function somewhat as spectrum analyzers.

Further, station monitor scopes are made to handle station monitoring chores, unlike oscilloscopes whose primary missions are for far more sophisticated chores. For example, the average station monitor scope comes equipped with audio level inputs, while you must use clip leads and, possibly, attenuator pads—if the audio drive is too high—so an oscilloscope can handle station monitoring.

And this brings us to the topic at hand, the Heathkit HO-5404 Station Monitor. It's a unit which is made to be part of an HW-5400 HF station, so it follows Heathkit's relatively recent change to a brown color scheme. Its price puts it in line with other station monitors on the market.

A competent unit, the HO-5404 arrives in two boxes. The first contains the chassis, motherboard, demodulator board, and their associated parts; the second contains the cathode ray tube.

As you first look at it, two things strike you: (1) You wonder why Heath used such a big box for so few components—the chassis is 11-1/4" x 12-1/8" x 1-3/8" and it weighs 10.6 pounds—and (2) you notice that it's an organized kit.

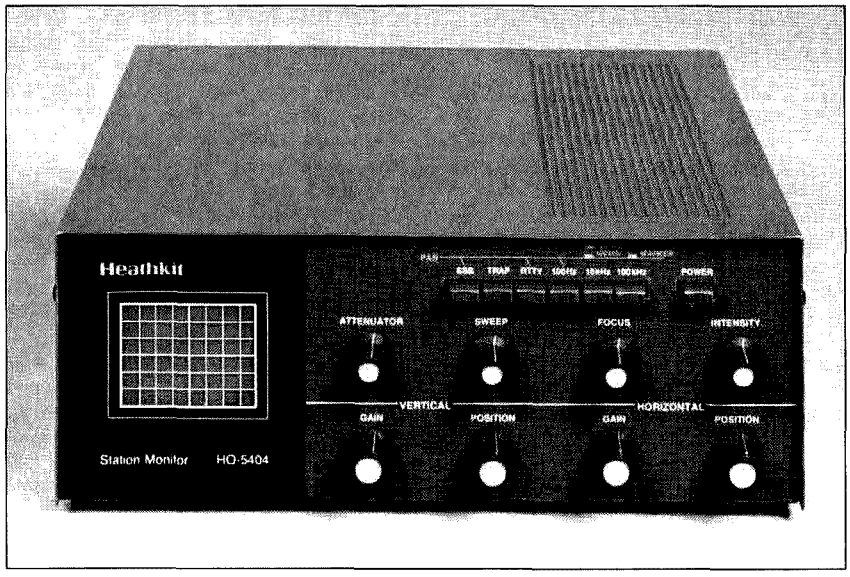
Rather than engaging in its former practice of providing bags and boxes of parts which were arranged in a seemingly helter-skelter manner, Heath has organized everything neatly and logically. Major subassemblies and their parts are grouped together so that everything is easy to find and check.

Once this is finished, the first major assembly is the demodulator board, after which you move on to the motherboard. The demodulator board takes about an hour or so to put together and the motherboard takes another four or five.

If you look carefully as you assemble the kit, you can see there is a subtle pattern in the way the components are mounted. As each wave of mounting washes across the board, you notice the close-mounted items, such as resistors and diodes, are mounted first. Then come the medium-height mounts, such as capacitors. Finally, the transistors are mounted. It does make things more convenient as you stuff the board.

With these items out of the way, you begin to assemble the chassis, with the rear connectors first. These connectors include antenna inputs as well as vertical and horizontal inputs. The attenuator switch and power line also are installed in this area.

After these connectors are installed, you turn your attention to the front of the chassis, which is probably the toughest part of the assembly.



At the front, the first step is installing a huge plastic decal. It not only contains the labeling for various potentiometers and switches, but it also serves as the graticule for the scope. It requires a great deal of care to do this correctly and I'd suggest lining up the work several times before you peel the covering off the back. The glue on the back holds like iron, and once you've put it on there's no turning back. So, if it's crooked, you're in for an interesting time trying to get it off and reposition it. Fortunately, rather than rush ahead, I took my own advice and lined everything up—and placed it on the first try.

"The real strength of the HO-5404 is that you built it and know it thoroughly. You can go in and troubleshoot a problem and replace a bad part."

The decal and the installation of the potentiometers and switches are the easiest steps of the process. Because once you've installed the switches—the motherboard is also installed about now—you must begin to wire them up in place. Not only does this call for care, it also calls for a steady hand with the soldering iron because it gets pretty crowded with wires and other pot-mounted components—capacitors, for example—very quickly. It's also a very tedious job that quickly becomes tiring and, as we all know, tiredness leads to inattention.

Once this is done, you must then wire up the switches, an even more tiring job because it seems like there are twice the number of connections to be made.

Quite frankly, this seems to be a time-wasting, backwards method of mounting and wiring switches and pots. I would urge the procedures to be turned around so that everything is wired up outside the chassis and then installed. This would make it easier for the kit builder, who would be worried only about the length of the leads instead of burning through wires in a jungle of tangled connections with already-installed components. It would also lessen the potential for mistakes because it is possible to attach a wire to the wrong point as the jungle of wires grows. The same is true of the switches.

Heath's HO-5404 Station Monitor.

NEW! Lower Price Scanners

Communications Electronics,™ the world's largest distributor of radio scanners, introduces new lower prices to celebrate our 15th anniversary.

Regency® MX7000-GS

List price $699.95/**CE price $469.95**
10-Band, 20 Channel • Crystalless • AC/DC
Frequency range: 25-550 MHz. continuous coverage and 800 MHz. to 1.3 GHz. continuous coverage.
The *Regency* MX7000 scanner lets you monitor Military, Space Satellites, Government, Railroad, Justice Department, State Department, Fish & Game, Immigration, Marine, Police and Fire Departments, Broadcast Studio Transmitter Links, Aeronautical AM band, Aero Navigation, Paramedics, Amateur Radio, plus thousands of other radio frequencies most scanners can't pick up. The *Regency* MX7000 is the perfect scanner to receive the exciting 1.2 GHz. amateur radio band.

Regency® Z60-GS

List price $299.95/**CE price $179.95/SPECIAL**
8-Band, 60 Channel • No-crystal scanner
Bands: 30-50, 88-108, 118-136, 144-174, 440-512 MHz.
The *Regency* Z60 covers all the public service bands plus aircraft and FM music for a total of eight bands. The Z60 also features an alarm clock and priority control as well as AC/DC operation. Order today.

Regency® Z45-GS

List price $259.95/**CE price $159.95/SPECIAL**
7-Band, 45 Channel • No-crystal scanner
Bands: 30-50, 118-136, 144-174, 440-512 MHz.
The *Regency* Z45 is very similar to the Z60 model listed above however it does not have the commercial FM broadcast band. The Z45, now at a special price from Communications Electronics.

Regency® RH250B-GS

List price $659.00/**CE price $329.95/SPECIAL**
10 Channel • 25 Watt Transceiver • Priority
The *Regency* RH250B is a ten-channel VHF land mobile transceiver designed to cover any frequency between 150 to 162 MHz. Since this radio is synthesized, no expensive crystals are needed to store up to ten frequencies without battery backup. All radios come with CTCSS tone and scanning capabilities. A monitor and night/day switch is also standard. This transceiver even has a priority function. The RH250 makes an ideal radio for any police or fire department volunteer because of its low cost and high performance. A *60 Watt* VHF 150-162 MHz. version called the **RH600B** is available for $454.95. A UHF 15 watt version of this radio called the **RU150B** is also available and covers 450-482 MHz. but the cost is $449.95.

NEW! Bearcat® 50XL-GS

List price $199.95/**CE price $114.95/SPECIAL**
10-Band, 10 Channel • Handheld scanner
Bands: 29.7-54, 136-174, 406-512 MHz.
The Uniden Bearcat 50XL is an economical, hand-held scanner with 10 channels covering ten frequency bands. It features a keyboard lock switch to prevent accidental entry and more. Also order part # **BP50** which is a rechargeable battery pack for $14.95, a plug-in wall charger, part # **AD100** for $14.95, a carrying case part # **VC001** for $14.95 and also order optional cigarette lighter cable part # **PS001** for $14.95.

NEW! Scanner Frequency Listings

The new Fox scanner frequency directories will help you find all the action your scanner can listen to. These new listings include police, fire, ambulances & rescue squads, local government, private police agencies, hospitals, emergency medical channels, news media, forestry radio service, railroads, weather stations, radio common carriers, AT&T mobile telephone, utility companies, general mobile radio service, marine radio service, taxi cab companies, tow truck companies, trucking companies, business repeaters, business radio (simplex) federal government, funeral directors, veterinarians, buses, aircraft, space satellites, amateur radio, broadcasters and more. Fox frequency listings feature call letter cross reference as well as alphabetical listing by licensee name, police codes and signals. All Fox directories are $14.95 each plus $3.00 shipping. State of Alaska–**RL019-1**; State of Arizona–**RL025-1**; Baltimore, MD/Washington, DC–**RL024-1**; Buffalo, NY/Erie, PA–**RL009-2**; Chicago, IL–**RL014-1**; Cincinnati/Dayton, OH–**RL006-2**; Cleveland, OH–**RL017-1**; Columbus, OH–**RL003-2**; Dallas/Ft. Worth, TX–**RL013-1**; Denver/Colorado Springs, CO–**RL027-1**; Detroit, MI/Windsor, ON–**RL005-3**; Fort Wayne, IN/Lima, OH–**RL001-1**; Hawaii/Guam–**RL015-1**; Houston, TX–**RL023-1**; Indianapolis, IN–**RL022-1**; Kansas City, MO/KS–**RL011-2**; Long Island, NY–**RL026-1**; Los Angeles, CA–**RL016-1**; Louisville/Lexington, KY–**RL007-1**; Milwaukee, WI/Waukegan, IL–**RL021-1**; Minneapolis/St. Paul, MN–**RL010-2**; Nevada/E. Central CA–**RL028-1**; Oklahoma City/Lawton, OK–**RL005-2**; Orlando/Daytona Beach, FL–**RL012-1**; Pittsburgh, PA/Wheeling, WV–**RL029-1**; Rochester/Syracuse, NY–**RL020-1**; San Diego, CA–**RL018-1**; Tampa/St. Petersburg, FL–**RL004-2**; Toledo, OH–**RL002-3**. New editions are being added monthly. For an area not shown above call Fox at 800-543-7892. In Ohio call 800-621-2513.

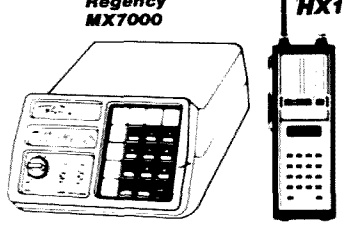
NEW! Regency® HX1500-GS

List price $369.95/**CE price $239.95**
11-Band, 55 Channel • Handheld/Portable Search • Lockout • Priority • Bank Select Sidelit liquid crystal display • EAROM Memory Direct Channel Access Feature • Scan delay
Bands: 29-54, 118-136, 144-174, 406-420, 440-512 MHz.
The new handheld *Regency* HX1500 scanner is fully keyboard programmable for the ultimate in versatility. You can scan up to 55 channels at the same time including the AM aircraft band. The LCD display is even sidelit for night use. Includes belt clip, flexible antenna and earphone. Operates on 8 1.2 Volt rechargeable Ni-cad batteries (not included). Be sure to order batteries and battery charger from accessory list in this ad.

Bearcat® 100XL-GS

List price $349.95/**CE price $203.95/SPECIAL**
9-Band, 18 Channel • Priority • Scan Delay Search • Limit • Hold • Lockout • AC/DC
Frequency range: 30-50, 118-174, 406-512 MHz.
The world's first no-crystal handheld scanner now has a LCD channel display with backlight for low light use and aircraft band coverage at the same low price. Size is 1⅜" x 7½" x 2⅜". The *Bearcat* 100XL has wide frequency coverage that includes all public service bands (Low, High, UHF and "T" bands), the AM aircraft band, the 2-meter and 70 cm. amateur bands, *plus* military and federal government frequencies. Wow...what a scanner!
Included in our low CE price is a sturdy carrying case, earphone, battery charger/AC adapter, six AA ni-cad batteries and flexible antenna. Order your scanner now.

Bearcat® 210XW-GS



List price $339.95/**CE price $209.95/SPECIAL**
8-Band, 20 Channel • No-crystal scanner Automatic Weather • Search/Scan • AC/DC
Frequency range: 30-50, 136-174, 406-512 MHz.
The new Bearcat 210XW is an advanced third generation scanner with great performance at a low CE price.

NEW! Bearcat® 145XL-GS

List price $179.95/**CE price $102.95/SPECIAL**
10 Band, 18 channel • AC/DC • Instant Weather
Frequency range: 29-54, 136-174, 420-512 MHz.
The *Bearcat* 145XL makes a great first scanner. Its low cost and high performance lets you hear all the action with the touch of a key. Order your scanner from CE today.

TEST ANY SCANNER

Test any scanner purchased from **Communications Electronics**™ for 31 days before you decide to keep it. If for any reason you are not completely satisfied, return it in original condition with all parts in 31 days, for a prompt refund (less shipping/handling charges and rebate credits).

NEW! Bearcat® 800XLT-GS

List price $499.95/**CE price $317.95**
12-Band, 40 Channel • No-crystal scanner Priority control • Search/Scan • AC/DC
Bands: 29-54, 118-174, 406-512, 806-912 MHz.
The Uniden 800XLT receives 40 channels in two banks. Scans 15 channels per second. Size 9¼" x 4½" x 12½."

With all of this done, the final step is installing and wiring up the CRT and connector. This, again, is straightforward, although it does pay to take care not to handle the CRT too roughly to limit chances of breaking it.

At this point, you're ready for the tuneup which also is straightforward and simply involves balancing the vertical and horizontal amplifier sections. This involves setting a couple of pots on the motherboard so that the circuits are balanced at 80 volts. It was at this point that I began to go somewhat gray as I kept on trying to get the vertical circuitry balanced and it wouldn't. Each time, one side would be at 80 and the other would be at 137, and when I adjusted the other side, the first would be out of adjustment.

Checking things out, it looked as if one of the driver transistors in the amplifier section was bad—Q104 and Q106—and I called customer assistance.

As I explained what was going on to the customer assistance rep, he quickly diagnosed the problem—Q104—and transferred me to the parts department where he had already ordered the new part to replace the offender on the motherboard. All I had to do was give my name and address. Less than a week later, the part arrived; I installed it, and everything was aligned quickly.

The acid test came when I put it on a rig and fired it into the dummy load. After adjusting everything according to instructions, I keyed the microphone and everything appeared as the documentation said it would.

I then went on to monitor my radioteletype signals, packet signals (just to see what they looked like), CW signals, and phone signals. As I watched the phone signals, one thing became clear to me: Too many operators have their speech compressors cranked up way too high and their signals are splattering all over the place. Nearly every signal I looked at on 75 was flat-topped and splattered everywhere.

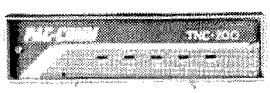
The strength of the Heathkit HO-5404 Monitor Scope isn't so much that it will serve as a good station monitor for VHF (1.8 to 54 MHz) or even as a reasonable 5-MHz scope (10–40-kHz vertical response and 10–300-Hz horizontal response) for bench purposes. It's a strong performer in both roles and is easy to use since there are only seven switches and eight pots in front, some of which you set once and forget.

The real strength of the HO-5404 is that you built it and know it thoroughly. You can go in and troubleshoot a problem and replace a bad part. This is possible because the scope uses discrete components rather than Very Large Scale Integration techniques. It is probably one of the few kits on the market that isn't stuffed full of ICs that you can't work on.

Another real strength is its documentation. Not only does it lead you step-by-step through the scope's construction and alignment, but it also guides you through troubleshooting procedures and gives suggestions should a problem arise. It also has a theory-of-operation section that explains precisely how the scope works, which is a refreshing change in this day of appliance manuals.

Further, the manual gives you valuable examples of the types of scope patterns you will see given a certain set of conditions (chirping, splattering, flat-topping, for example).

Despite these strengths, there is a sobering thought that occurs to me and that is cost. Operators used to build kits because they were less-expensive alternatives to over-the-counter gear. But with Heathkits costing nearly the same as fully assembled gear, it makes you wonder why an operator would build instead of buy.



In my case, I feel a sense of satisfaction, but I can't say that I've learned anything from it, other than how to stuff a board. I also am familiar with the innards of the gear and it is fairly easy to work on. But I can't say that this is the situation with the rest of the amateur world. Surely, there are many who agree with me, but there are many more who would prefer to plunk down their plastic and buy ready-made gear.

And who's to say who's right? The only piece of advice I have for Heath is to consider realigning the pricing structure of their gear. If they can afford to cut margins and make their equipment the low-cost alternative again, they'll stand a chance of revitalizing a whole marketplace. Heath's equipment is good and something you can get your hands on. Now, isn't that something in this day of tiny rigs and tinier parts? You bet it is! Reader Service number 151.■

PAC-COMM

GIVES YOU MORE CHOICES

TNC-200

- World-standard TAPR hardware design
- Internal modem operates at 1200 or 300 baud
- Active filter improves modem sensitivity
- Five labeled LED status indicators
- Terminal baud rates 300,1200,2400,4800,9600
- Works with any RS-232 terminal or computer
- Battery backup for 16K RAM memory
- CMOS draws only 135ma (typ), NMOS 250ma (typ)
- World standard TAPR software command set
- AX.25 Version 2 protocol fully implemented
- Up to 10 simultaneous connections
- Supports Level 3 networks (in development)

	CMOS	NMOS
Assembled and Tested	$219.95	$199.95
Full Kit with cabinet	$169.95	$154.95
Kit without cabinet	$144.95	$129.95
Hard-to find Parts	$ 84.95	$ 79.95
PC Board and Assy Manl		$ 39.95
Reference Manual (100+ pages)		$ 9.95
Command Reference Card		$ 2.00
Cabinet with End-plates		$ 29.95

PTU-200

Packet Tuning Indicator/HF Modem

- Single push button selection of HF/VHF
- Active bandpass filter helps copy in QRM
- 20 segment red LED bar graph display
- Internal TAPR-design modem
- Power switch controls both PTU and TNC
- Works with any TAPR TNC-1 or TNC-2 clone
- Cabinetry matches TNC-200 design
- Installation is simple and convenient

Assembled and Tested $149.95
Full Kit and Cabinet $114.95

MACPACKET

Terminal Software for Macintosh

- Pull down menus, split screen
- Works with any "TNC-2" or clone
- stored digipeater routing tables
- File upload and download and more

Available now for only $69.95

PC-PACKET

Terminal Software for your PC

- Split screen or multi-color display
- Multiple, scrolled pages of rec'd/xmit buffer
- Fully configurable PC and TNC parameters
- Works with all TNC's (including GLB PK-1)
- Pop-up windows for operator interface
- User-definable function keys
- Printer/disk logging, DOS access

Available now for only $49.95

PC-100

Dual Port Packet Controller

- Dual Port TNC on a half size card
- Use With your PC or compatible
- TNC software included
- Dual 300/1200 high performance modems
- Provisions for high speed external modem
- Use as Network Controller, Gateway, etc.

Assembled and tested $189.95
Full kits from $149.95

Tired of listening to all the chatter on your favorite VHF/UHF repeater while waiting for that important call?

Auto-Kall
AK-10

You don't have to anymore with the **Auto-Kall, AK-10,** a ready-to-use DTMF (Touch-Tone*) selective calling system. All you add is the radio!

FEATURES:

- ★ Completely assembled and ready to use. Simply connect to external speaker jack on your rig. Audio mini-plug patch-cord included
- ★ Easy setting of your personal 3-digit code in seconds with small rotary switches. No jumpers to solder.
- ★ 8-15 VDC for mobile/portable operation or use supplied 117 VAC power supply for base station operation.
- ★ Built-in 8-OHM speaker turns on when your code is received to let you hear the station calling
- ★ Resets automatically to silent-standby and leaves red LED on to let you know someone called if you were away from the rig
- ★ CMOS circuitry provides for low current operation
- ★ Measures only 1¾ x 3 x 5½ inches.

Only $79.95 (Plus $3.00 Shipping/Handling)

A Rotatable *What?*

WA2VUN rotates an unguyed, 86-foot, 2100-pound tower on a "lazy susan"—and lives to write about it!

This project started about two years ago while I was in the midst of erecting a Tri-Ex DX-86 tower in Spring Valley, New York. No doubt about it, the DX-86 is a lot of tower, standing 86 feet tall when fully raised and capable of supporting 25 square feet of wind loading. At 2100 pounds, it's probably the biggest crank-up available to amateurs.

I had previously owned a Tri-Ex LM-470, but was intrigued with the thought of 16 extra feet and additional capacity, since plans had been in the back of my head to put up arrays for 40 meters through 23 cm and build a super contest station. Unfortunately, the number of yagis I had in mind would exceed the wind load capacity of even the best rotors available.

Sure, a custom-built rotor would have fixed this problem, but as a welder I have certain skills and resources not available to most amateurs. Why not use a fixed mast to support the huge yagi arrays and rotate *the entire tower?* Why not, indeed! And so began one of the stranger but more rewarding projects I've ever been involved with.

The DX-86 was ordered from Tri-Ex and I set about creating the specifications. First, I'd need a strong mast—*very* strong. Not only that, since it couldn't rotate down or be dropped (being securely fastened in one position), some method of climbing the mast easily to do antenna work was needed.

The solution was to employ two separate pieces of pipe, the first a 21' x 2" piece of extra-heavy-wall seamless steel, the second a 28' x 1-1/2" piece which slid inside the first piece. Next, I cut sections of 5/8" Rebar and drilled the combination mast every 20", sliding the Rebar sections through to pin the two masts together and form a ladder to climb up. Neat!

Next, the top of the DX-86 was modified by replacing the mast guide with 2-1/2" pipe fitted with a steel plate so as to form a key at the lower end. This was bolted to the tower in place of the old mast guide. The combination mast section had a key slot machined into its lower end to fit into the steel plate, resulting in an extremely strong support. The 256-lb., 28-foot mast could now support two climbers to allow antenna work in any tower position, up or down. I could remove the mast if needed by lifting it out with a ginpole or small crane.

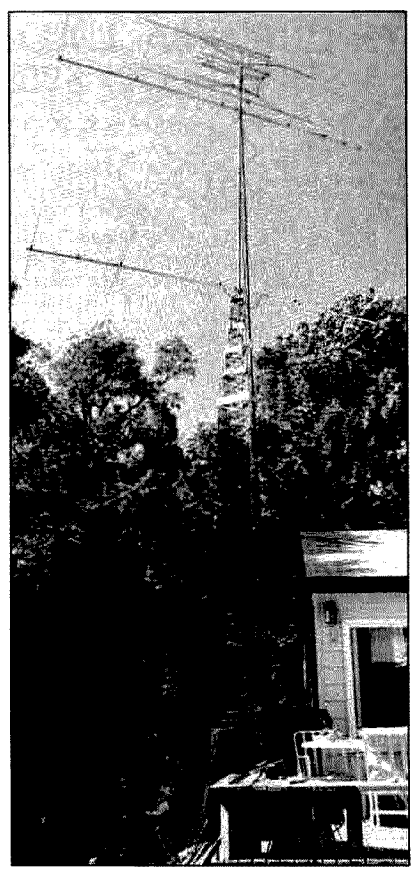

Photo A. The completed tower with about half of the antennas installed. Even in the cranked-down position it is over 60 feet tall. (Photo by KT2B.)

The DX-86 employs five sections, with extra-heavy cross bracing, thick walls on the extension sections, and roller guides to cut down on friction during crank-up or crank-down. However, I did replace the stock 1-HP, 220-volt crank motor with a remote-controlled 24-volt system so as to allow crank-up and crank-down operations from inside the house. This system was designed by Paul Olsen and features on/off lamp indicators for the "end of crank" limit points, as well as limit switches on the tower itself. These were very important, as I wouldn't be able to see the tower from my shack during operation.

While I was tackling the cranking problem, I decided to employ a custom-designed rotor-indicator system. (Remember now, I was rotating the entire DX-86 on a pedestal!) An old friend, Bob Nyire WA2AJV, came up with the solution, employing selsyn motors and indicators which were modified for the application by Phil Anderson W2HWG. These motors are connected to the rotor gear mechanism (I'll get to that in a moment) and allow a 400-degree rotation. Those of you who have operated contests or chase DX will remember the times you had your rotor on the east side of south and heard a rare one just the other side of south! This allows the extra rotation needed to make that contact. Limit switches kick in beyond this point.

On to the rotating pedestal. As with most big tower projects, you've got to start with a hole in the ground. The spot I chose for the DX-86 allowed no room for digging equipment, so I did it the good old-fashioned way—by hand. After getting about 2-1/2 feet deep rather quickly, I hit

hardpan, the next best thing to solid rock. Talk about tedious work! I measured progress in inches each day after work, but after many backrubs and jars of liniment, the hole was 6-1/2 feet deep by about 4-1/2 feet on a side, and it was time to pour the concrete base.

Allowing for a 6" form above the ground, it would take about 7 yards of concrete to do the job. Before this could be done, a steel anchorage for the pedestal base needed to be installed. This was made from 450 pounds of #7 and #8 Rebar welded into a cage form four feet on a side and six feet high. Additionally, I welded eight 8-inch pieces of 1-inch threaded rod to the top of the cage, which would protrude through the concrete and form the anchor points for the pedestal.

The pedestal carries the full weight of the DX-86 and supports the drive gear and turntable as well. For this application, I selected steel angle stock in 4'x 6'x 1/2" and 4'x 4'x 1/2" lengths. The shape is much like a pyramid with the top chopped off, tapering upward. The bottom is four feet square and sits nicely on the eight anchor bolts.

Total pedestal height is 6 feet. The retracted tower on the pedestal measures over 60 feet to the top of the mast! Fitted to the top of the pedestal is a 3-foot-diameter plate of 1-inch-thick steel. This plate has been machined with eight 3" slots that hold roller bearings, which in turn support a 1-3/8"-thick plate that forms the base of the tower.

"The rotor can rotate virtually any tower—even a good, straight utility pole if need be."

Here's where it gets tricky: Since this plate and the bearings form a "lazy-susan" arrangement, I had to grind, re-grind, and re-re-grind the plate to make sure it was absolutely flat. Nothing would look more unappealing than an 86-foot tower wobbling around in circles. Sure wouldn't help the neighbors' confidence level, either, especially those within 90 feet of the tower!

To complete the picture, I had to construct a means of turning the lazy-susan arrangement and provide additional support for this mass of metal balanced on a 3-foot plate. This was accomplished by selecting a piece of 6"-diameter, 1/2" wall steel tubing and welding a 6" heavy-duty pipe flange to one end. This was then turned in a lathe to make the flange absolutely square to the pipe. This shaft passes through both the upper rotating plate (which it's bolted to) and the lower bearing-support plate, via a 6"-diameter roller bearing.

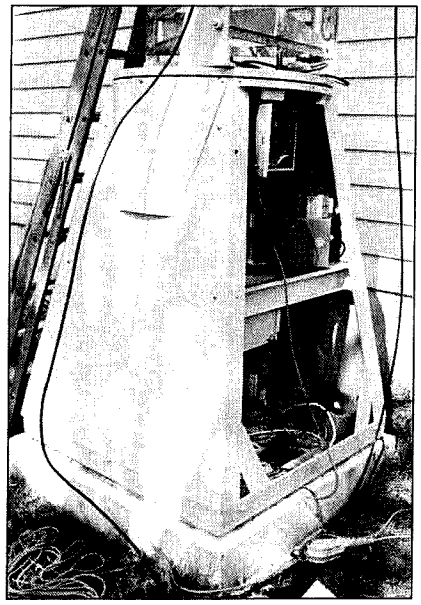

Photo B. The base pedestal with the cover removed. The large concrete base is visible, as is the lazy-susan turntable at the top. (Photo by KT2B.)

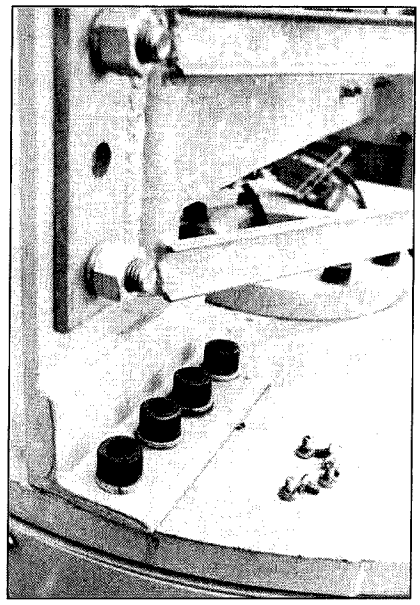

Photo C. Close-up of the method used to attach the tower to the rotating plate. (Photo by KT2B.)

The lower end of the shaft is also supported by a roller bearing to restrict side wobble and ensure proper centering. In addition, this end has a 22"-diameter, 1/2" #50 roller chain sprocket attached to it, forming the drive mechanism. A smaller roller chain sprocket on the shaft drives the selsyn position indicators and activates the limit switches when necessary.

To actually turn the beast, I selected a Dayton 1/2-HP, 120-V-ac motor rated at 1725 rpm output. Fastened to the drive gear is a double-reduction Ohio Gear Manufacturing right-angle worm drive, resulting in an 11-rpm shaft speed. Next, I fitted a 2-1/4", #50 roller chain sprocket to the output of the worm drive—and this is what drives the 22" sprocket on the rotor shaft. The final output torque from the motor/drive combination is about 20,000 lb!

The DX-86 will rotate a full 400 degrees in about 62 seconds, and do it with about as much noise as a small TV antenna rotator—it's that quiet. Best of all, there are no solenoid brakes to seize up or worry about (a common problem with Ham-4 or TailTwister rotors). The final touch was to paint the

pedestal the same color as my house siding, so it blends in better.

Current plans are to install the following antennas (some, if not all, will be up by the time you read this):

4-element, 144-MHz yagi (FM)
7-element, 220-MHz yagi (FM)
Four 23-element, 1296-MHz arrays
Two 19-element, 432-MHz arrays
Two 17-element, 220-MHz boomers
Two 19-element, 144-MHz boomers
Two 7-element, long-boom 50-MHz yagis
Hy-Gain 205 BAS for 20 meters
Hy-Gain 105 BAS for 10 meters
Telrex TB-5 Tribander
KLM 3-element, 40-meter beam

The design, construction, and installation of this rotating tower took about one year (dovetailed into my work and play schedule) working days, weekends, and even nights where needed. As mentioned earlier, my main business is welding and fabrication. Note that all materials used are strictly "off the shelf" with the exception of the rotor, which can rotate virtually any tower—even a good, straight utility pole if need be.

If readers would like further details regarding construction and operation, I'd be glad to provide details upon request. (Please send an SASE.)

I'd like to thank the following people for making it all possible: my two kids, Jennifer and Matthew, for helping dig the hole; Bob Nyire WA2AJV for all his thoughts and input regarding the rotor and controls; Paul Olsen for the lift electronics design; Phil Anderson W2HWG for his help on the selsyn indicators; and finally, my wife, Jo-Ann, for putting up with all of the long hours I spent at my shop. ■

HF Antennas: All Bands, All Wire

Coax-hater W0VM resurrects the versatile tuned doublet for nine-band HF use.

With eight high-frequency amateur bands (1.8, 3.5, 7, 10, 14, 21, 24, and 28 MHz) and one more band to be added soon (18 MHz), it is not practical to have a separate coax-fed dipole for each band. It would also be difficult to design a trapped antenna that would work on all of these bands. However, by using the kinds of antennas that were common in early days of amateur radio, *one* antenna can be made to provide good results on all of these bands.

If an historian were to write a history of amateur radio antenna design, he would divide this history into two periods. The first period would be the B.C. (before coax) period in which the objective of antenna design was to obtain the best possible performance. The second period would be called the A.C. (after coax) period. The convenience of coax, combined with human laziness, changed the course of amateur antenna design—antennas had to perform with coax feedlines. It has now become apparent that much performance was sacrificed in order to have coax feedlines. This was especially true with respect to multiband antennas. Now, many hams are using B.C.-type antennas.

Such an antenna can be built for very little money. Furthermore, on the higher bands, these antenna systems have *gain* as compared to a half-wavelength dipole. When erected in the form of an inverted vee, these antennas send and receive well in all directions.

The purpose of this article is to describe three nine-band antenna systems, to give approximate values of their gain for each band (as compared to a half-wave dipole for that band), and to present the directional patterns for each band.

All three of these antenna systems are fed with balanced tuned feeders and require a little work in adjusting an antenna tuner (or "transmatch") that has a balanced rf output. This little bit of work provides greatly improved performance as compared to a coax-fed antenna.

Antenna Number One

The first antenna to be discussed is a half-wavelength centerfed zepp for 3.5 MHz (the correct name for this type of antenna is a "tuned doublet," but it is commonly called a centerfed zepp). Each side of the center insulator should be approximately 66 feet long. (The exact length is not important so long as the wires on each side of the center are the same length; 60 feet could be used if that would be more convenient.) The tuned feedline can be made of either open-wire (ladder) line or of good quality twinlead (preferably of the heavy-duty transmitting type). It is often convenient to use open-wire line from the center of the antenna to the grounding switch outside of the shack and to use twinlead from

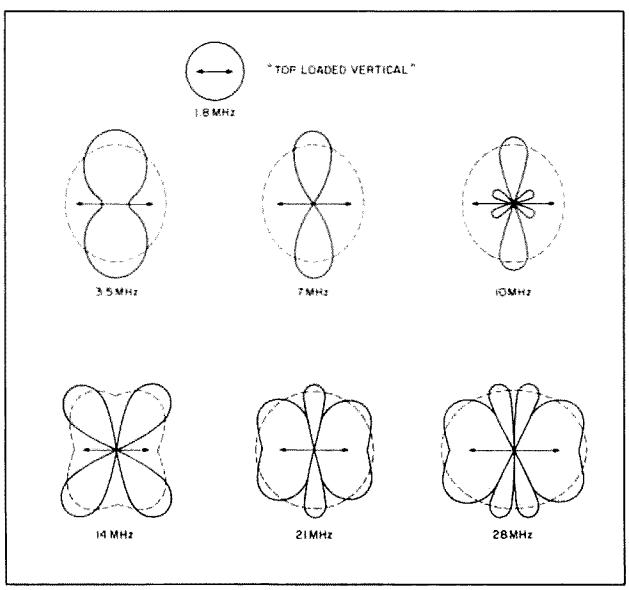

Fig. 1. Approximate directional patterns for antenna number one (66 feet each side of the center). The dotted lines show the patterns when the antenna is in the form of an inverted vee.

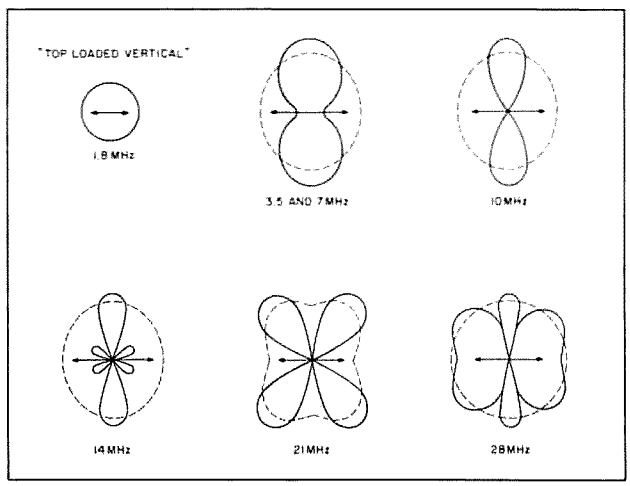

Fig. 2. Approximate directional patterns for antenna number two (51 feet each side of the center). The dotted lines show the patterns when the antenna is in the form of an inverted vee.

the grounding switch to the antenna tuner inside the shack.

Some amateur operators think that tuned feeders (or resonant lines) must be in the form of open-wire or ladder lines. This is not true. Excellent results can be obtained using good quality twinlead. The feedline to my big tuned doublet contains about 50 feet of homemade open-wire line and about 50 feet of three different kinds of twinlead, all in series.

The directional patterns and gains of this antenna (as compared to a dipole for each band) are shown in Fig. 1, and how to use the antenna system on the 1.8-MHz band will be explained later in the article.

On the 3.5-MHz band, the antenna system functions as a half-wavelength dipole. However, it will work much better than a coax-fed dipole because the antenna system can be tuned to resonance at the exact frequency being used, whether the frequency is near the low end of the CW band (3.500 MHz) or near the high end of the phone band (4.000 MHz). The antenna will send and receive best at right angles to the antenna wires. However, if the antenna is in the form of an inverted vee, it will send and receive reasonably well in all directions. For best east and west coverage, the antenna wires should run north and south.

Antenna engineers do not consider the inverted-vee configuration to be a good antenna design. Having the ends of the antenna nearer the ground than the center introduces losses not present when the antenna is horizontal. If the antenna is an inverted vee, it is a good idea to have the angle between the wires at the center of the antenna at least 120 degrees. In spite of the views of antenna engineers, many amateurs use inverted-vee antennas with good results.

On the 7-MHz band, the antenna will function as two half-wave antennas fed in phase. *It does not* function as a full-wave antenna, as was erroneously stated in a past *73* article ("So Why Do They Call It Wireless?" March, 1985). The gain as compared to a 7-MHz dipole will be 1.8 dB plus whatever gain can be attributed to the use of tuned feeders instead of coax feed. The strongest signals will be at right angles to the antenna, but an inverted-vee configuration will provide good coverage in all directions.

On the 10-MHz band, this tuned doublet will be even more effective. It will function as a long "extended double zepp" with a gain of nearly 3 dB as compared to a half-wavelength dipole, and with the greatest signal strength at right angles to the antenna wires.

On the 14-MHz band, the 3.5-MHz tuned doublet functions as two one-wavelength antennas fed with rf currents in phase. This provides a four-leafed-clover radiation pattern with lobes 52 degrees from the line of the wires. (As usual, the inverted-vee configuration will provide coverage in all directions.) The gain in the directions of the lobes should be at least 1 dB.

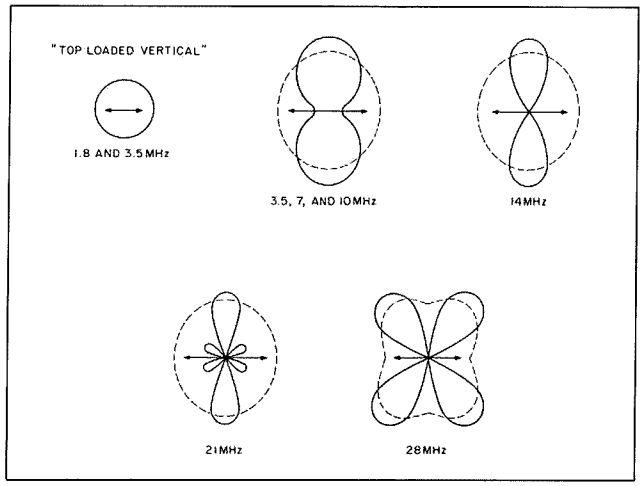

Fig. 3. Approximate directional patterns for antenna number three (33 feet each side of the center). The dotted lines show the patterns when the antenna is in the form of an inverted vee.

On the 18-, 21-, 24-, and 28-MHz bands, there will be four main lobes and two or more minor lobes. As the frequency gets higher, the angles that the four main lobes make with the direction of the wires become smaller and smaller, and minor lobes (at nearly right angles to the wires) appear. On the 21-MHz band, the antenna functions as two 3/2-wavelength antennas with rf currents in phase, and the gain in each major lobe should be at least 1.5 dB.

On the 28-MHz band, the antenna functions as two two-wavelength antennas with currents in phase, with gains in the major lobes of at least 3 dB. (In spite of extensive reading of antenna articles, I have been unable to find gain figures for the 14-, 21-, and 28-MHz bands using the 3.5-MHz tuned-doublet antenna, so the gain figures presented are guesstimates. The actual gains probably would not be less than these figures and might be more. One antenna authority wrote that the gain on the 28-MHz band should be 4 dB in the main lobes.)

Antenna Number Two

A tuned-doublet antenna system does not necessarily have to have its wires any particular length so long as each wire is exactly the same length as the other one. Moreover, a length can be chosen that will favor certain bands. A good length to have each side of the center is 51 feet. This is the length made popular by G5RV. An antenna with 51 feet each side of the center is slightly less effective on the 3.5-, 7-, and 10-MHz bands than the antenna with 66 feet each side of the center, but it is more effective on the 14-MHz band because it is a long (3/4-wavelength) extended-double-zepp antenna with a gain of nearly 3 dB on that band. The antenna sends and receives best at right angles to the antenna wires on the 3.5-, 7-, 10-, and 14-MHz bands. The four-leafed-clover radiation pattern does not develop until it is used on the 21-MHz band.

The gain figures for this antenna on the 3.5-, 7-, 10-, and 14-MHz bands are as follows: 3.5 MHz—none, 7 MHz—1.5 dB (guesstimate), 10 MHz—at least 1.8 dB, and 14 MHz—nearly 3 dB.

On the 21-MHz band, the main lobes would be in a four-leafed-clover pattern with the angles of the lobes 52 degrees from the line of the wires, and the gain in the main lobes estimated to be at least 1.5 dB. There would be a similar pattern on the 28-MHz

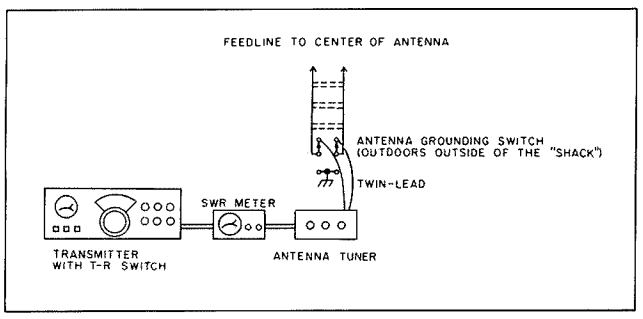

Fig. 4. The antenna system's connections to the transmitter.

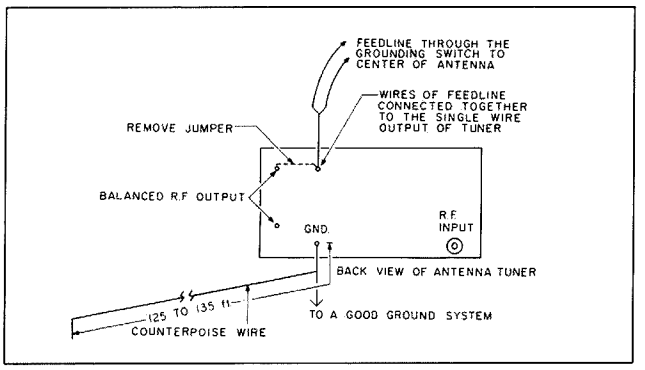

Fig. 5. Connections for using the antennas as top-loaded vertical antennas.

band with the angles of the lobes to the wires being a bit smaller than that of the 21-MHz lobes.

Both of the above-described antennas can be used on the 1.8-MHz band by connecting the ends of the feedline together on the single-wire output of the antenna tuner. There should be a good ground connected to the tuner. A "counterpoise wire," 125 to 135 feet long, connected to the ground post of the tuner, helps. (This wire can be strung along a fence in the yard or otherwise supported above the ground. The counterpoise wire does not have to be stretched out straight but can be located wherever there is space and can have many bends in it.) When used in this way on the 1.8-MHz band, these two antennas will be functioning as "top-loaded vertical antennas" with the feedline part of the system doing the radiating. The antenna wires provide the "top loading." This top-loaded vertical will send well in all directions with perhaps a bit more in the directions of the wires.

Antenna Number Three

Where space is limited, an antenna with shorter wires can be used. This third tuned-doublet antenna has wires 33 feet long on each side of the center. Although it will load up and make contacts on the 3.5-MHz band, it probably would work better as a top-loaded vertical antenna on that band. (This was the experience of N0EVQ.)

On the 7-MHz band, this antenna system functions as a half-wavelength dipole with best directions at right angles to the antenna wires. (An inverted-vee configuration provides coverage in all directions, as is the case with the other two antennas.)

On the 10-MHz band, the antenna could be considered an elongated half-wave dipole or a much shortened "two half waves in phase" with best directivity at right angles to the antenna wires and with some gain as compared to a half-wave dipole.

On the 14-MHz band, the antenna would be "two half waves in phase" with a gain of 1.8 dB as compared to a dipole and best directivity at right angles to the antenna wires.

On the 21-MHz band, the antenna would be two 3/4-wavelength wires fed in phase. This would be an elongated extended double zepp with best directivity at right angles to the wires and with a gain of at least 2 dB as compared to a dipole.

On the 28-MHz band, the antenna would function as two full-wavelength antennas fed with currents in phase and with a four-leafed-clover directivity pattern with lobe angles of 52 degrees from the line of the wires. A gain of at least 1 dB in each lobe could be expected.

This antenna could be used as a top-loaded vertical on the 1.8-MHz band, connected as described earlier in this article.

Although this article has shown how to use these antenna systems on only the eight HF bands that we now have, they will certainly work well on the 18-MHz band after we get it.

When these antennas are used as top-loaded vertical antennas, the gain (or loss) and directivity patterns will vary with each installation. On the 1.8-MHz and 3.5-MHz bands, there will actually be loss as compared to a half-wave dipole for the band. (The antennas will work as top-loaded verticals on other bands, and trying this on the other bands could provide some interesting results.) The effectiveness of these antennas when used as top-loaded verticals will depend on the antenna's height above ground and on how nearly vertical the feedline (now the radiator) is. The higher the antenna is the better, and the more nearly vertical the feedline is the better. Vertical antennas send in all directions. It should be noted that the 1.8-MHz band is a vertical-antenna band because it is extremely difficult to put up a horizontal antenna high enough to be effective on this band (250 feet). As one writer put it, "On the 160-meter band, a horizontal antenna compares favorably with a dummy load."

Choosing Antenna Size

The choice of which nine-band antenna system an operator should build will depend on the space available, which bands are his favorites, and what other antennas, if any, he may have. For example: If space is available and the operator already has a triband beam antenna for the 14-, 21-, and 28-MHz bands, a tuned-doublet antenna system 66 feet each side of the center is the logical choice. It provides 1.8-MHz operation when used as a top-loaded vertical. The 3.5-MHz performance is much better than a coax-fed dipole on that band. The antenna provides a gain of 1.8 dB on the 7-MHz band and a gain of nearly 3 dB on the 10-MHz band. The triband beam can take care of the 14-, 21-, and 28-MHz bands.

If the operator's favorite band is the 14-MHz band and he does not have a beam antenna, the antenna with 51 feet each side of the center is the logical choice. The gain on the 14-MHz band would be nearly 3 dB because the antenna is a long, extended double zepp on that band.

The smallest of the three antennas would be used where there is not enough space for either of the larger antennas. There is nothing sacred about the lengths of 66 feet, 51 feet, and 33 feet each side of the center. Lengths between these can be used as long as the lengths each side of the center are the same. Longer wires favor the lower frequencies. I had an antenna with 40 feet each side of the center that worked very well on the 7-, 14-, and 21-MHz bands. For anyone who wishes to maximize the performance on any particular band, the extended-double-zepp lengths each side of the center are as follows: 7 MHz = 84 feet; 10 MHz = 60 feet; 14 MHz = 44 feet; 21 MHz = 28 feet; 28 MHz = 25 feet.

Using the Tuned-Doublet Antenna System

The antenna system is connected to the transmitter as shown in Fig. 4. The transmitter's output is connected through the T-R switch (built into transceivers and most transmitters) by a short piece of coax to the input of the swr meter. The output of the swr meter is connected to the input of the antenna tuner (or transmatch) by another short piece of coax. The feedline from the antenna is connected to the balanced output of the antenna tuner.

Using low-power output from the transmitter, the antenna tuner is adjusted until the swr meter shows little or no reflected power. The transmitter is next loaded up to the desired power, and the antenna tuner's dials are "touched up" to provide minimum reflected power showing on the swr meter. With a good antenna tuner, it is usually possible to tune up so that there is practically no reflected power. After this has been done, the frequency and tuner settings should be recorded for future use. Finding the correct tuner settings for several frequencies in each amateur band takes time. However, once these frequencies and tuner settings have been recorded, the operator can quickly tune his antenna system to resonance at the desired frequencies by looking at the recorded dial settings.

Conclusions

It would be difficult, if not impossible, to design and build a coax-fed trapped antenna that would work on all nine bands. If such an antenna could be designed, it would have *loss* on each band compared to a half-wave dipole for the band being used. Besides not being very good, the cost of such an antenna would be outrageous. (A trapped antenna for *only three bands* costs in the neighborhood of $130.) Any of the three nine-band antenna systems in this article could be built for less than $50. The performance on each band would be much better than could be obtained from a nine-band coax-fed antenna, even if such could be designed and were available.

If you prefer the *best possible performance*—and don't mind a little extra—then the antenna systems described in this article are for you.

Build one of these antennas, use tuned feeders, and experience the excellent results you can obtain on all bands by using *one* well-designed antenna system. ■

Watts My Line

Transmission-line tutorial— K4IPV explains four common types.

The transmission line is the wire that connects the output of your transmitter to the antenna or other load. For most of us, the transmission line will be a piece of coaxial cable with a surge impedance of either 52 or 75 Ohms. Fortunately, the antenna manufacturers and transceiver manufacturers conspire with each other to standardize designs. All we normally have to do is connect the standard output of our transmitter to a standard 52- or 75-Ohm coaxial cable and the cable to the standard input at the antenna feedpoint.

Not all of us are able to use standard values, however, and for this type of situation we need to know a little bit about transmission lines. Not much, mind you, but a little. There are, for example, times when we will have to make our own transmission line. That's right, I said *make*! This point was driven home to me recently by a DX contact who is engaged in missionary broadcasting in the wilderness some place or another in Africa. He pointed out that low-budget radio stations often have to make do with local materials, and for him that meant making his own special impedance transmission line for use in a quarter-wave matching section.

You remember the old formula: $Z_o = \sqrt{Z_L Z_S}$? Unfortunately, the value of transmission-line impedance calculated for his situation did not compare favorably with one of the standard values—which weren't available anyway. He had to use the formula for parallel-feeder surge impedance to find appropriate spacing for the diameter conductors that he did have available. It worked!

In this article, I'll look at some of the most common forms of transmission line and show you how to calculate the surge impedance. There also is a program in Basic that will aid in the calculation for four types of transmission line: coaxial cable, parallel feeders, shielded parallel feeders, and VHF/UHF/microwave "microstrip" lines.

Characteristic, or "Surge," Impedance

We frequently bandy about the "impedance" of transmission lines. We refer to 52-Ohm or 75-Ohm coaxial cable, for example. Just what is this impedance? Note that two terms are used for transmission-line impedance: characteristic impedance and surge impedance. As far as I can tell from my literature search, they are the same and so will be used as such here.

The surge impedance of a transmission line is derived from the distributed inductance and capacitance of the line. All forms of transmission lines exhibit these parameters. The capacitance comes from the fact that the two conductors are in close proximity, while the inductance comes from the length of the conductors (no doubt there is also some mutual inductance).

The impedance is $Z_o = \sqrt{L/C}$, where L is the inductance per unit of length in henrys (e.g., H/ft.), and C is the capacitance per unit of length in Farads (e.g., F/ft.).

Note that the impedance is not dependent on length because length appears in both numerator and denominator of the above equation. I have heard supposedly knowledgeable people tell Novices and engineering students that characteristic impedance is measured in "Ohms per foot," and since impedance is resistive in nature it can be measured on an ohmmeter! Horse feathers!

The surge impedance could also be defined in a naive manner by stating that it is the value of terminating resistance (i.e., load impedance) that will not reflect any power back down the line. Thus, when a 75-Ohm transmission line is connected to a 75-Ohm resistive load, none of the forward power is reflected back down the line toward the transmitter.

Coaxial Cable

Perhaps the most widely used transmission line is coaxial cable (see Fig. 1). The name of this transmission line is derived from the fact that the two conductors have the same axis and thus are *co*axial (Fig. 1(a)). The coaxial cable consists of an inner conductor surrounded coaxially by an inner insulator and an outer conductor. An optional outer insulator is also provided on most types (Fig. 1(b)).

The outer conductor is usually braided copper, sometimes tinned and sometimes not. In some special types of coax, however, the outer conductor (or shield) may be aluminum foil (color-TV transmission line), helical armor (like BX electrical cable), or solid pipe (used in some broadcast applications). In the last case, the coax might be fitted with gastight flanges and ceramic spacers (internal). That type of coax is used in high-power,

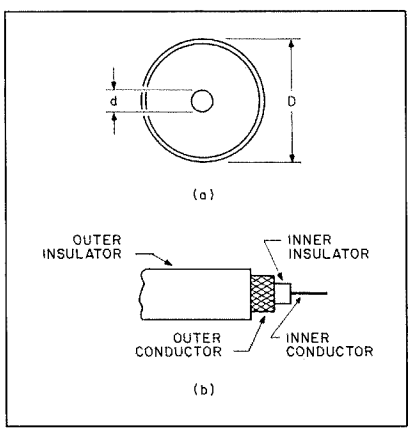

Fig. 1. Coaxial cable.

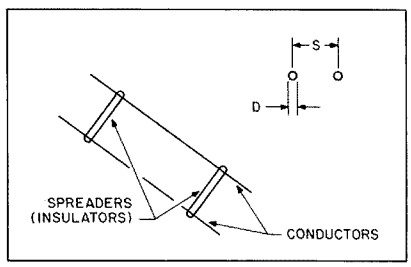

Fig. 3. A parallel feeder.

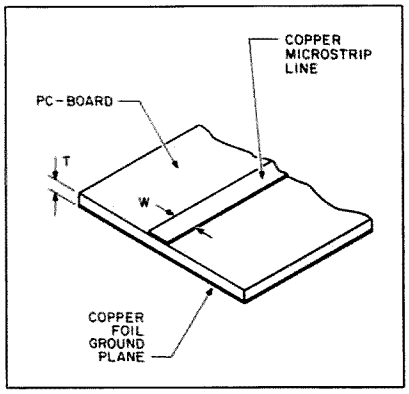

Fig. 4. A common microstrip configuration.

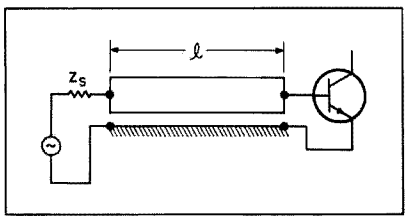

Fig. 5. Schematic representation of a microstrip transmission line.

low-frequency applications, and its dielectric is dried nitrogen gas.

The inner insulator for most types of coax is not quite so exotic, however. Materials such as polyethylene, poly foam, and Teflon™ are used.

One factor affected by the type of inner conductor is the velocity factor (V). This factor is the percentage of the speed of light, expressed as a decimal fraction, that the radio wave travels inside of the coax. Thus, when we say that a foam dielectric coax has a velocity factor of 0.8, we are saying that the radio signal inside the cable propagates at a velocity of 0.8 times the speed of light (0.8C). The velocity factors for common types of coax are 0.66 for polyethylene, 0.80 for poly foam, and 0.70 for Teflon.

The characteristic impedance of coaxial cable is given by $Z_o = (138/\sqrt{E} \times \text{Log}(D/d)$, where $E = 1$ for air, and $1/V^2$ for other dielectrics.

Shielded Parallel Feeders

Shielded parallel feeders are not used extensively by amateurs but are found in television applications. One suspects that users of folded dipoles and certain other types of antennas that are amicable to this form of transmission line might want to consider it because of TVI.

An example of shielded parallel line is shown in Fig. 2. Note that the transmission line consists of two conductors parallel to each other and surrounded by a shielded braid not unlike coaxial cable. The surge impedance of this transmission line is given by $Z_o = (276/\sqrt{E}) \times \text{Log}\{[(1 - B^2)/(1 + B^2)] \times 2A\}$, where $A = S/D$ and $B = S/R$.

Commercial types of shielded parallel lead are available in 300-Ohm surge impedance

capable of delivering several hundred Watts to the antenna. I have found that this kind of line gets too warm when a kilowatt is used. While that experience is almost two decades old by now, I have little reason to believe that a strictly television-reception type of line will perform effectively on a high-power transmitter antenna. With a standard 100-200-Watt transceiver, however, there will be little problem provided that impedance matching at the feed end of the line is done correctly.

Parallel Feeders

This is the type of transmission line spoken of by my DX contact in Africa (see Fig. 3). This was the first type of line used by amateurs that wasn't a simple length of wire indistinguishable from the antenna itself! The line consists of two parallel inductors separated by an insulator—usually air, in amateur transmission lines. (TV twinlead is the same sort but uses vinyl insulation.)

Amateurs typically use solid or stranded wire for the conductors, except when making certain matching sections and ceramic spreaders for insulators. I have seen spreaders sold with several notches for the conductors along the length so that distance between the conductors can be varied to obtain a specific impedance value. There are two versions of the formula, but the simplified case, that assumes an air dielectric, is Z_o = 276Log(S/D).

Parallel feeders can be built for almost any practical impedance that you might need. In most cases, we will know the impedance and can select standard diameters for the conductors from available stock. In that case, we will want to solve the above equation for the spacing, S, which is exactly what most texts delete: $S = D10^{Z_o/276}$, where D is the conductor diameter, Z_o is the desired impedance, and S is the spacing. (S and D must be specified in the same units, e.g., feet, meters, inches.)

Microstrip Line

Microstrip line is a form of transmission line used at VHF, UHF, and microwave. It is formed on printed circuit boards (see Fig. 4). This transmission line is formed from an etched conductor on the board surface counterpoised against a copper-foil ground plane on the other side of the board. Obviously, double-sided board is needed. The characteristic impedance is given by $Z_o = (377/\sqrt{E_t}) \times (T/W)$, where Z_o is the characteristic impedance, W is the conductor width, T is the board thickness, and E_t is the dielectric constant of the board material. Fig. 5 shows a typical use of a microstrip line in a UHF or microwave amplifier.

Computer Program

A computer program for the impedance equations used in this article is shown in the listing. This program is in the MS-DOS Basic used in the IBM PC and should be compatible with other Microsoft Basics. In any event, the program is easily translatable for other Basics—something I had in mind since I have both Apple and IBM PC computers. ■

Scaling the Wet Noodle

It's ham radio's equivalent of a ship in a bottle: Evaluate your antenna's design with a quarter-scale model.

Have you ever had an idea for a new antenna system and would like to know how well it might perform without doing too much work? Then consider reducing the antenna's size, so you can modify and test it without wearing yourself out raising and lowering the brute. Fortunately, the amateur frequency assignments are almost ideal for scale models. Scale modeling is accomplished by reducing the size of the antenna by some scale factor, then increasing the test frequency by this same factor. For example, a one-quarter-scale model of a 160-meter antenna can be tested on the 40-meter band (4 x 1.8 MHz = 7.2 MHz). With a little more ciphering, you can determine all other possible combinations.

Wanting to get on 160 meters, but not having the real estate necessary to erect an inverted vee or a dipole, I was stuck with putting up some kind of vertical that would be reasonably efficient and small in size (these aren't very compatible). Since I have had some experience in designing top-loaded vertical antennas, I came up with the idea of utilizing both capacitive and inductive top loading (not original by any means).

After scouting around a little, I located a source of 20-foot sections of fiberglass pipe varying in diameter from 1.5 inches to 3 inches; they could be telescoped. This looked like an ideal mast for what I had in mind.

For the capacitance hat, I thought I might use several spokes made from small-diameter aluminum tubing, mounted on a disk/hub assembly that could be bolted to the top of the fiberglass mast. The loading coil could then be wound on the mast slightly below this capacitance hat.

Now came the design problem: How much inductance would be required to resonate this structure in the middle of the 160-meter band? I could see myself raising and lowering the antenna several times, using the old "try and try again" technique. Here my 70-year-old friend Willie W5FXP came to the rescue by suggesting I build and test a quarter-scale model. Willie, as usual, was quite persistent. So, since he was willing to help, why not?

For the full-scale model inductor and antenna wire, I had located an inexpensive source of industrial-grade insulated solid-copper wire (#12 THHN). This wire with insulation was approximately 1/8 inch in diameter. Dividing this by 4 produced a scale-model wire diameter of 0.03125 inches,

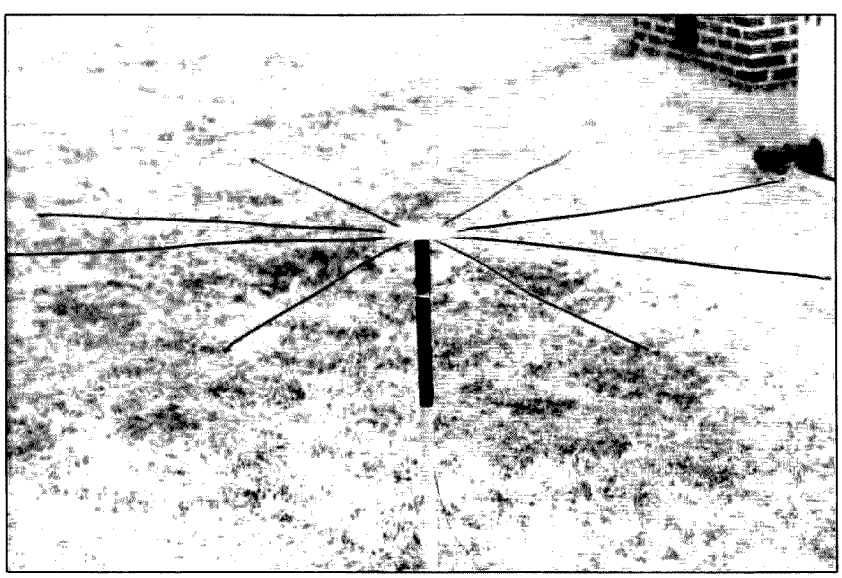

Photo A. Bird's-eye view of the quarter-scale top hat and loading coil.

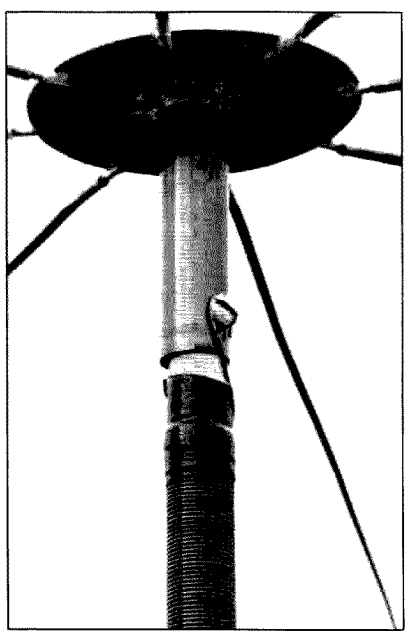

Photo B. Construction details of the quarter-scale top hat.

Photo C. Quarter-scale antenna held by full-scale W5RRH. The full-scale antenna mast can be seen in the background.

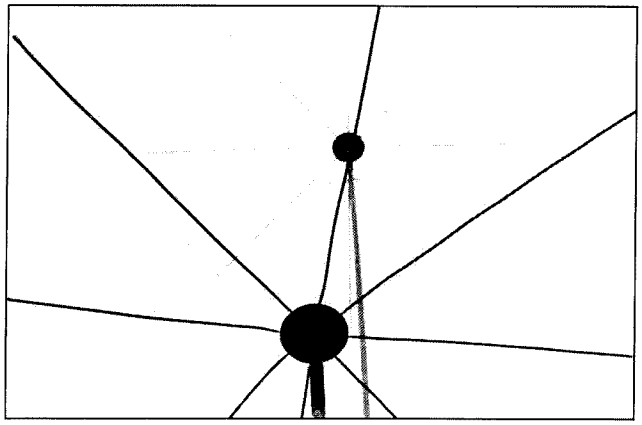

Photo D. Quarter-scale and full-scale top hats and loading coils.

about the same as #20 wire. We figured this should be suitable for the quarter-scale model inductor and antenna wire.

I had decided on using the 1.5-inch fiberglass pipe for the full-scale mast, sliding this into a short piece of 2-inch fiberglass pipe which would be set in concrete. This would give me an overall mast height of approximately 25 feet. Scaling this down by a quarter dictated a coil form 1/2 inch in diameter, and a mast 6 feet 3 inches high.

Next came the capacitance hat. For the full-scale model, I had acquired four 12-foot sections of 1/2-inch aluminum tubing. Cutting these in half would provide eight "spokes," each 6 feet in length. For mounting, a 6-inch-long 2.062-inch-i.d. aluminum tube was welded to the center of a 12-inch-diameter aluminum disk. This tubing would slide down over the top of the 2-inch-o.d. fiberglass mast. The spokes could then be bolted on the top of this disk.

The scale-model spokes needed to be 0.125 inches in diameter and 1.5 feet long. Not having any #8 wire (0.128-inch-diameter), we decided to use the #12 wire instead, knowing this would provide slightly less top-hat capacitance. A 3-inch-diameter piece of copperclad circuit board became the scale-model disk, and a piece of 1/2-inch thin-wall copper pipe became the scale-model mounting tube. All of these scale-model pieces were soldered in place.

The scale-model loading coil was wound on a 1/2-inch-diameter wood dowel rod. After much discussion, Willie and I decided to start out with 150 turns. We estimated that this would be a few turns too many—but it is always easier to take off than to add on. The quarter-scale model was assembled and mounted such that the capacitance hat was exactly 6 feet 3 inches above a good ground, this being a radial ground system consisting of 32 radials varying in length from 20 to 45 feet. These were the maximum lengths possible, without encroaching on the XYL's flower beds or the neighbors' yards.

Using a grid-dip oscillator, we determined that the resonant frequency was a little too low, the target being 7.2 MHz. After several cycles of "remove a few turns and try again," we ended up with 111 turns. The next step was to see how well the antenna performed, so we connected some RG-8 coax cable from the scale-model antenna and ground system to my HF transceiver. All indications were that we hit everything right on the money. The impedance was quite low (swr approximately 4:1), but with the aid of a coupler I was able to load up to full power.

Since it was getting late in the day, we decided to cease the proceedings. Besides, Willie wanted to see what kind of signal this little antenna would put out over at his house (about a mile away). Willie rushed home and got on the air. Not only did he report an S9 +40 signal, but we also made contact with two other stations, George K7DY in Tucson and Bill W4KFB in Louisville. George gave me a 5-8 report and Bill a 5-9. Needless to say, there was considerable discussion about my miniature antenna.

Next came the "proof of the pudding." Using the material described previously, we assembled the 25-foot full-scale model. Since the quarter-scale model was resonant at 7.2 MHz, we estimated that the same number of turns on the full-scale model loading coil would resonate the antenna at approximately 1.8 MHz, which is too low for practical purposes. After a little discussion, we decided that 105 turns would be about right, but added another five for good measure. This proved to be a mistake because we had to take it all down and remove those five turns.

The full-scale antenna performed about as we had expected. Again, the impedance was quite low. We estimated that the radiation resistance was about 1 Ohm and the ground-loss resistance about 11 Ohms. Willie suggested that I use a 4-to-1 bifilar-wound toroid transformer at the base of the mast to step the impedance up to approximately 50 Ohms. This worked exceptionally well, the swr being 1:1 at the resonant frequency.

After this success, I got a little greedy and decided to add another 20 feet to the height. A 20-foot section of 2.5-inch fiberglass pipe was acquired and plans made to extend the structure accordingly. Naturally, at the insistence of Willie, we had to do the scale modeling again. It was a good thing we did, however, because we discovered that another 10 turns had to be removed from the loading coil to make everything close to the same resonant frequency.

Erecting the 45-foot full-scale model was quite an experience. With Willie holding the base on the ground against the concrete-mounted short mast, I started the usual "walk-up" procedure. After I reached the midpoint, I looked around and discovered the top hat had barely cleared the ground. Due to the antenna's conflict with a small tree, I had to let it back down and start over again. Unfortunately, unknown to us, one of the top-hat spokes was put into a bind and cracked right at the outer mounting bolt. After we moved the structure so that it would clear the tree, back up it went. Willie said that the base of the mast was up about 50 to 60 degrees before the top started up, then it really got with it.

After reaching the vertical, the top hat waved around as if it were mounted on a wet noodle! Having anticipated this undesirable flexibility, I had attached two levels of guy ropes to the mast. After we slipped the mast over the ground post and bolted it in place (another struggle), we adjusted the guy ropes until Willie was satisfied everything was vertical and straight. Eventually, the cracked spoke fell off, but we weren't about to let the antenna back down just to replace one spoke. This reduced the top-hat capacitance, increasing the resonant frequency about 30 kHz—which was where I really wanted it anyway (about 1.885 MHz).

If you want to see a seven-spoke top hat and a 105-turn top-loading coil supported by a 45-foot wet noodle, come on by. It does get me on 160 meters, however. If I were going to do it again, I think I would use either larger diameter fiberglass pipe or, even better, large diameter aluminum tubing for the main part of the mast, then use a short section of fiberglass or PVC pipe for the loading coil. Oh well, hindsight is always better. At any rate, the scale modeling was quite interesting. As Willie said, "Besides, it was FUN!" ■

The Missing Link?

Work the world with your HT using WB2REM's simplex controller.

This article is copyrighted by James I. Millner.

Motivated by feelings that all hams have experienced, I became obsessed with the idea of communicating worldwide with only a hand-held VHF/UHF transceiver. Thus, I designed a remote link that changed my VHF/UHF operations and one that will bring excitement to yours.

Can you picture yourself riding a bicycle in the neighborhood, or even miles away, and QSOing with someone on the other side of the USA or the world? Do you drive a lot and are you tired of the mundane operations of 2 meters but do not have the room for an HF rig? Are you a DX buff and do you have anxiety attacks over missing rare DX stations while you are at work? Then this project is for you!

As a prerequisite for this project you will need a simplex autopatch or similar device, touchtone™ decoder, UHF or VHF transceiver, as well as an HF rig. Knowledge of digital electronics is needed, although I was initially very naive on the subject and learned by trial and error.

My first working link design employed three Radio Shack 22/44-pin printed-circuit-board cards. In addition to related circuitry, over ten relays were spread out among the boards. After further consideration, I employed a 7420 (TTL-4 input NAND gate), which replaced many of my relays. The newest revision, reported in this article, is contained on one Radio Shack 22/44-pin board and will enable you to operate your HF rig at your house by using just your VHF/UHF HT or mobile transceiver.

The simplex link requires a simpatch sampling device. I chose the CES 510SA because of its special access features, especially the line-in-use code option. That option allows you to interrupt a telephone call in progress only by inputting a three-digit touchtone code from your remote transceiver. These codes can be manipulated to activate the link. This link was designed for use with the CES 510SA Revision B, although instructions are given for Revisions C, D, and E. Other types of simplex autopatches can be used as well with special modifications. It is also advisable that you use a fast-switching VHF/UHF rig in conjunction with the simpatch. Besides the HF rig (which can be any type), a DTMF decoder (like a Silicon System SS 202P) will be needed. Outputs of the DTMF decoder should be 5 volts.

The block diagram (Fig. 1) illustrates the operations of the simplex link system. Basically, a touchtone signal originating from your remote transceiver is received by the VHF/UHF transceiver connected to the link. The signal is passed through the touchtone decoder, causing a voltage shift from +5 V to ground while the touchtone is present. These voltage shifts in turn send messages to the ICs and relays, which activate the link.

The link performs a number of functions. It supplies power to your low-band rigs and controls your mode of operation. The link turns on in a receive-only mode. This will allow you to chat on your VHF/UHF HT while monitoring the HF band in the background. The patch silences the HF receiver audio when you transmit on your HT. Through touchtone commands you can switch into a transceive mode. Here, all signals received by your VHF/UHF transceiver are simultaneously transmitted on the HF band. A beep follows your transmission to verify your HF transmission. Finally, the link switches out the phone line and reinserts the HF-receiver audio into its place.

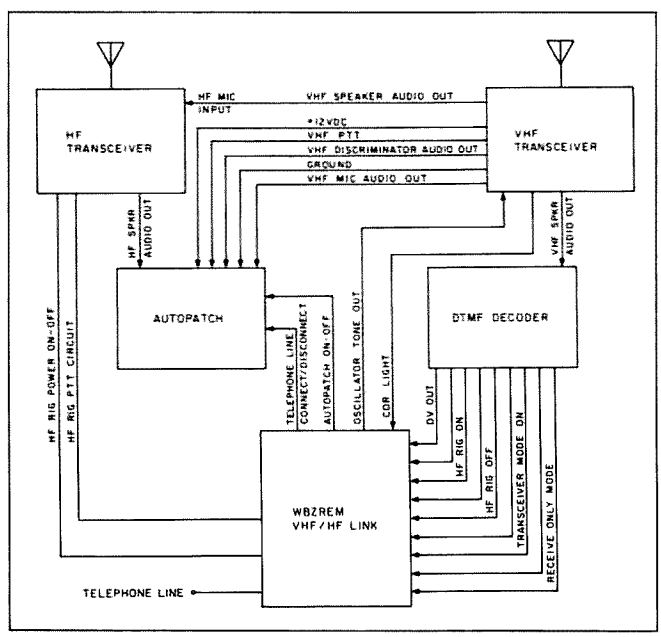

Fig. 1. Block diagram.

Circuitry

Electrically, the link consists of two 2-tone latches composed of: three 7400s, a 7420, two 556 timers, an oscillator, three 5-volt relays, and one 12-volt relay. All components are mounted on the Radio Shack 22/44-pin board except for RL1, the 12-V relay. Photo A shows how tight the fit is. All ICs and relays should be mounted as close to each other as possible on the 22/44-pin board. One of the 2-tone latched circuits is used to trigger the 4PDT relay (RL1), which turns the HF rig on, disconnects the telephone line, and inserts HF-re-

ceiver audio. The other switches the link from receive to transceive mode.

At the central core of the link is the 7420 (U5), a 4-input NAND gate. When each of the four inputs of this IC simultaneously receives a +5-volt signal, a relay (RL3) is activated, which triggers the PTT switch of your HF rig.

Pin 1 of the 7420 is connected to the output (pin 3) of one of the 2-tone latches (U3). The latch output is at ground potential until triggered by the transceive-mode touchtone access code. The output then shifts to +5 volts. LEDs connected to the inputs of the 7420 indicate the presence of input signals. In returning to receive-only mode, the output of U3 drops back down to ground.

Pin 2 of the 7420 is connected to the output of a 74123 (a monostable multivibrator). It sounds obscene but is merely a timer. In the link this output is normally at +5 volts, but it shifts to ground potential for one second when triggered by DV. DV is a line that comes out of most touchtone decoders and responds to every valid touchtone by shifting to +5 volts for as long as a tone is present. This circuitry in the link is used to mute the transmission of touchtones over the HF band and, in effect, momentarily takes the HF rig out of transmit when a touchtone is decoded. I have found that DV and/or the decoder is

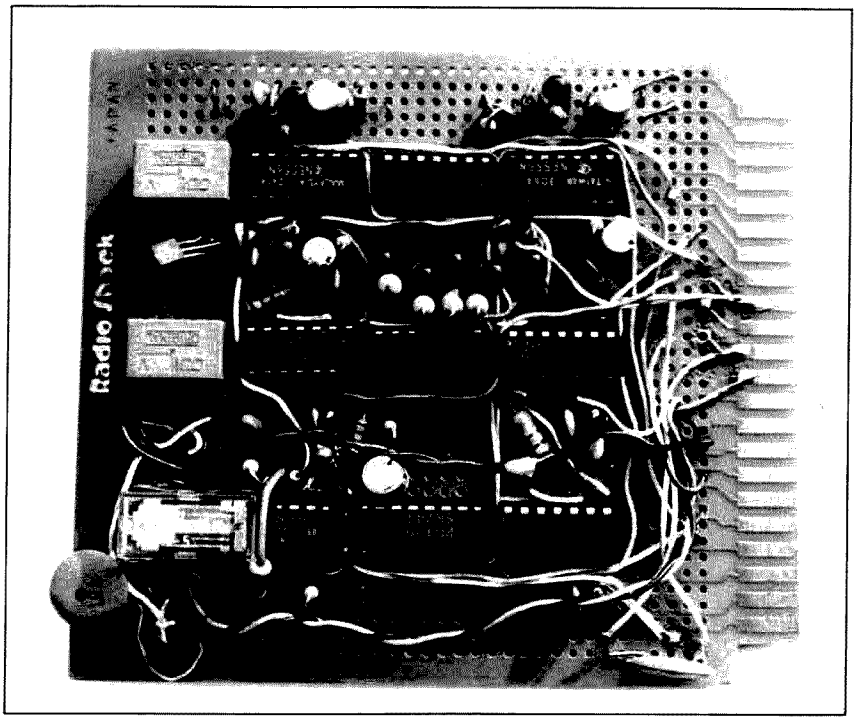

Photo A. A complete simplex link on one tiny board.

1	47k, 1/4 W	.10
4	1N4004 diodes	.15 ea.
4	Red LEDs	.20 ea.
3	2N2222 transistors (RS 276-1617)	$1.98/pkg.
2	556 ICs (T1, T2) (RS 276-1728)	$1.49 ea.
1	74123 IC	$1.50
3	7400 ICs (U1, U2, U3) (RS 276-1801)	.89 ea.
1	7404 IC (U4) (RS 276-1802)	.99
1	7420 IC (U5)	.99
1	555 IC (OSC1) (RS 276-1723)	$1.19
7	14-DIP sockets	.20 ea.
1	16-DIP socket	.20
1	8-DIP socket	.20
2	5-V, 2-A SPDT relays (RL2–RL4) (RS 275-243)	$2.49 ea.
1	5-V, 1-A DPDT relay (RL3) (RS 275-215)	$3.99
1	12-V, 10-A 4PDT relay (RL1) (RS 275-218)	$5.49
1	22/44-pin circuit board (RS 276-154a)	$2.99

most susceptible to rf interference. If rapid switching of the low-band relay occurs, shield the decoder from rf.

Pin 5 of the 7420 is connected to your simplex-autopatch in-use voltage. In the CES 510SA, this point can be tapped off of the positive side of R18 in Revision B (R29 in Revisions C, D, and E). At R18, +12 volts is present when the patch is in "standby." When activated, it drops to ground potential. This shift is inverted by the 7404 and applies 5 V to pin 5 of the 7420.

Finally, from a connection to the squelch, COR light, or other carrier-sensing device coming from your VHF/UHF transceiver, you will need to use that voltage to drive a 5-V relay. This relay's normally open contacts will then apply 5 V on pin 4 of the 7420 whenever a signal breaks the squelch of your VHF/UHF rig.

Once all four conditions are met, relay RL3 will short the push-to-talk wires of your HF rig and put it into transmit. A beep will come back after you stop transmitting. This beep is generated by the 555 (OSC1) oscillator. The length of the beep can be changed by varying *R1 or C1*, the tone pitch by *R2 or C2*, and volume by changing R3. If you cannot immediately hear the beep, open your remote transceiver's squelch. The beep may be coming back too quickly.

Hookup

Refer to Fig. 1, the block diagram. To interconnect your VHF/UHF base station to the simplex autopatch and HF rig, you will need very good shielded wire. This is to reduce any floating rf, which could adversely affect your circuitry. If you have problems with rf, try putting a .01- or .1-uF capacitor to ground at critical points like the outputs from the decoder and IC outputs.

Your first step in connecting the link is to follow the factory instructions for installation of your simplex autopatch to your VHF/UHF rig. Next, you should connect a shielded wire from the receiver audio of your VHF/UHF rig and run it to the microphone audio line of your low-band rig. I was able to make this connection directly, but you may need an audio transformer in the circuit. Next, run shielded wire from the HF-rig push-to-talk line to the normally open and common contacts of the DPDT (RL3) relay. From the receiver audio line of the HF rig, run a shielded wire to the audio insert point in your simplex autopatch. This is done through a 1-uF capacitor. In the CES 510SA Revision B, this connection is made between T1 and C18 (C22 in Revisions C, D, and E).

Testing the Link

To activate the link, key in the "line in use" and "autopatch on" touchtone codes on your VHF/UHF remote transceiver and set your decoder's output with them. These codes cause relay RL2 to switch relay RL1. Relay RL1 has several functions: It supplies power to your HF rig, disconnects the telephone line from the autopatch, and switches the HF-rig receiver audio into the autopatch. The HF audio will be heard through the normal simplex autopatch sampling method. Adjust the audio level of your HF rig by listening on your remote transceiver (HT). You will find that the volume adjustment should be lower than normal listening level. To go into transceive mode, key in your designated touchtone codes. There will be a slight delay (1/4 to 1/2 second) and your HF PTT will be activated. Talk into your remote transceiver (HT) and adjust your low-band microphone level at the same time as reducing or increasing the VHF/UHF rig receiver level. This will ensure a proper HF-band modulation level. If your microphone gain is too high, it may affect the operation of the decoder. So, if you notice that the touchtones aren't muting on the HF band, lower your HF-band microphone gain and/or increase VHF/UHF receiver gain.

It must be noted that, in this type of link operation, extreme courtesy should be exercised. Since you will probably be able to operate only on one HF frequency (unless you have a computer-controlled transceiver), you should always ask if the frequency is in use, as in normal operation. This applies to your VHF/UHF simplex frequency as well.

Secondly, in accordance with FCC rules and regulations, you should have a separate control link to your setup. I use a telephone-line control system, which you can purchase at Radio Shack or Sears. It turns my complete station's electricity on/off by signals sent through the telephone line.

Conclusion

For the last couple of years I have enjoyed many contacts through the link, all of which have been exciting experiences. I have gone auto mobile, bicycle mobile, walking mobile, barbershop portable, and dentist-chair portable.[*"Mumph glumph, rumph, aaack, ouch—Please rinse and spit" echoing through the HF bands.—Ed.*] The implications for use in emergency situations, retirement communities, and apartments are unlimited.

I view linking as a new frontier in amateur radio. The possibilities are limitless as to where, how, and with whom it can be done. You can link 220 MHz to 2 meters, or 440 FM to 15-meter SSB. Most importantly, it is done on simplex and does not tie up a repeater.

So get out in the air, take a ride in the country, or just lie on the beach because now you can rest assured that if you get the sudden urge to call CQ DX, your big rig is as close as your HT.

At this time I would like to thank Dick Spair K2ASG, whose expert skills regarding linking provided me with the backbone for writing this article. I would also like to thank Jerry Lutin N2ERB, who painstakingly transcribed my chicken-scratch schematics into a work of art. In addition, I would like to acknowledge Dick Maly N2COH, Mark Winderman WA2HCS, and Lou Cordas K2EWT for their invaluable help. ■

Dishing It Out On 10 GHz

Learn how to build simple feed systems for microwave antennas. (Includes an explanation of the mysterious "baggies" effect.)

I have always been mystified by antennas and feeds for use on microwave frequencies. I used to think that most of the technology that is needed is far too advanced for me to tackle—and this held me back from constructing units for myself. The black-box technology held the most mystery for me. I hope in this article to dispel any fears on the very special black-box designs needed to make these antennas work. The techniques that I will present cover designs I have built and used. While there is a degree of black-box magic going on, it did not prevent me from obtaining some very efficient antennas with very simple tools.

I started this project by constructing an antenna feed for 10 GHz before I even contemplated any receiver or transmitter, since I had obtained the piece of waveguide first. Being a scrounger, I couldn't refuse a part that could be put to use sooner or later.

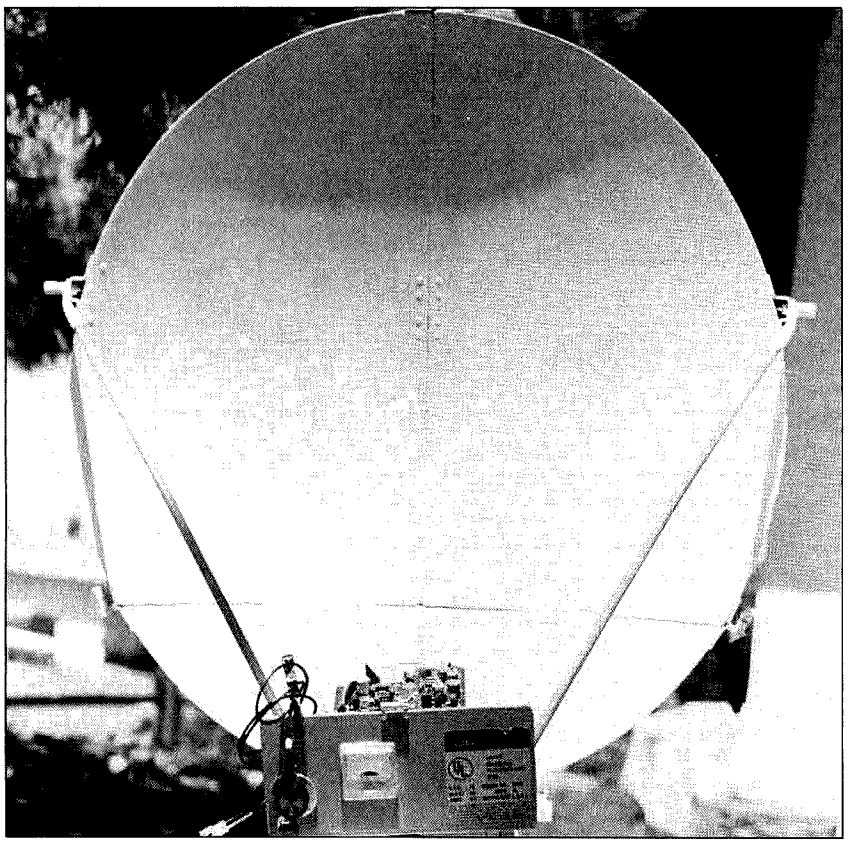

Photo A. Off-center-feed 10-GHz dish with original transceiver mounted at focus. Used for Mount Soledad to Mount Helix contacts.

Dipole Feed

The first feed that I constructed was a simple dipole feed equipped with a reflector spaced behind the driven element. This feed was constructed from one shown in the *RSGB VHF Handbook*. Fig. 1 shows the details. The actual construction of this feed was started on a scrap piece of waveguide 16 (WG-16), which has dimensions of .5 by 1 inch outside and .4 by .9 inches inside. This piece of waveguide was cut back for a distance of 2 inches from the front with a .125-inch edge lip clearance. The triangular area was cut away with a hacksaw and then filed down to the scribe marks as shown in Fig. 1. This vee cut is made in the .5-inch side of the waveguide. When you have removed the triangular piece from both ends of the waveguide, bend the upper and lower sections together to form a duck-bill tapered end. Move both upper and lower sections an equal amount.

In the dead center of the point of contact, a one-quarter-inch slot is cut into the front face of the vee that is now formed together. This slot has a width of about .064 inches ± .002 inches. The depth of the slot is .250 inches. Into this slot is placed a 1-inch-wide, .050-inch-thick piece of brass 1.250 inches long. The assembly is hard-soldered and all dimensions are checked for accuracy. All excess solder is removed from the inside of the guide as well as from the pieces—use as little solder as possible to make the cleanup job easier.

After you are satisfied that the parts have not shifted during soldering, you can drill the holes for the dipole and reflector in the .050-inch piece of brass. My elements were made from a .75-inch length of .125-inch brass stock obtained at a model train shop. I made the pieces longer than necessary to facilitate soldering and cleanup. In this way I only had to file them, after checking them with a caliper or micrometer to determine when

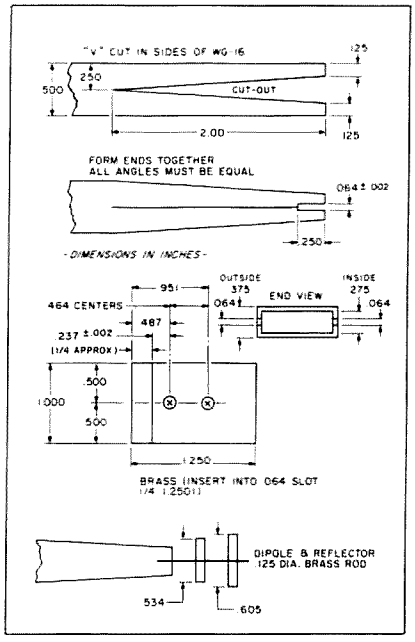

Fig. 1. Construction details for the 10-GHz dipole feed.

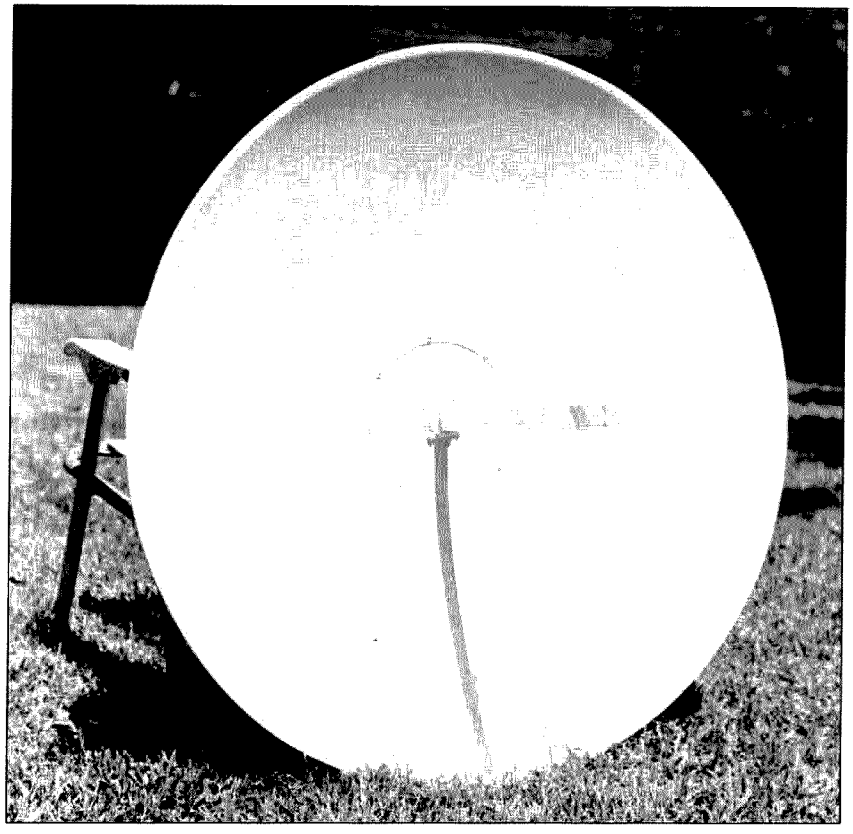

Photo B. 10-GHz dish antenna with dipole feed and dielectric resonator (plastic bag) in place.

they were cut to the proper length. Make checks often, as it is surprising how much material can be removed from this brass stock, and also check the spacing to the center stock to ensure that the elements are balanced in length.

Parabolic Dish Feed

I must have waited almost two years for other parts of the system to come into play before I was able to adapt the previous feed to a parabolic dish. I had been looking out for one for a long time without much success. I had even eyed the Sears Snowcoaster as a possible dish, but regarded the shape as too inefficient on close evaluation. Just not the right shape—close, but not right. I looked at many of the construction articles on dish antennas and thought about making one, but never did. I guess I was looking for the perfect inexpensive available dish antenna.

I finally found the perfect dish in one of the most unlikely places, but I came close to missing it completely. Only the intervention of a friend who was parked in a nearby truck prevented it. As I guided him out of a tight spot in a parking lot, I spotted the dishes. In the trash dumpster were two light reflectors, the type you see hanging from most high-school gyms for lighting the basketball court. The price made the acquisition even more desirable! They were 30 inches in diameter and had a large hole in their center. A small piece of metal could take care of that very easily. When I brought the two very dirty reflectors into work, some of my fellow hams thought I had lost some, if not all, of my marbles. Little did they know what madness was at work. After all, being a scrounger, one must be ever alert.

I was impressed by the curvature and the simplistic idea that if a reflector was made to do a good job with a light bulb, why not at lower frequencies, say 10 GHz? The depth of the curve from the outer edge to the center was 4.75 inches. With a diameter of 30 inches, the focus is equal to the diameter squared divided by 16 times the depth. In this case, the focus would be placed at approximately 11.8 inches. I took the dishes home and cut an 8.5-inch piece of round aluminum to cover the hole and soon was mounting the feed that I had made so long ago.

Dipole Feed Trials

I tested the dipole feed in my garage and in my backyard and the results were very encouraging. The antenna showed a very narrow beamwidth and quite a lot of improvement in gain over the 18-dB horn that I was comparing it to. Calculations showed that if all were operating well, I should expect about 35 dB of gain from this antenna system. I did not get a chance to add a matching screw network, as the gas tank used for the soldering operation was in need of a refill. See Fig. 2 for details on the screw tuner used to improve the match on waveguide 16.

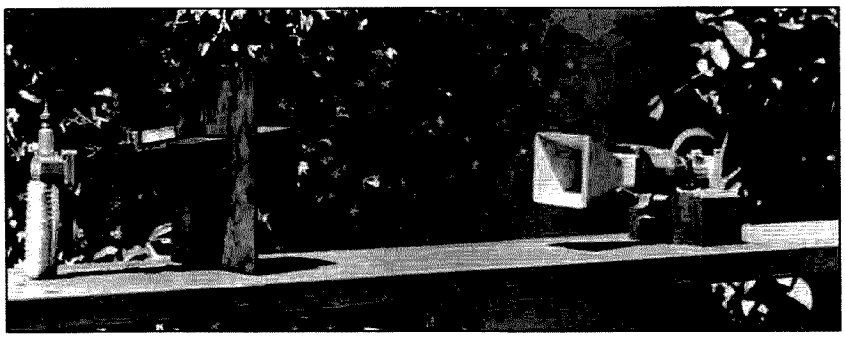
Field Tests

My partner in this venture, Kerry Blank N6IZW, and I had tested the system performance with our transceivers located over short paths of about two to five miles, and we were eager to try a longer path. Kerry traveled to Mount Soledad on his lunch hour and I went to Mount Helix, as both these areas were within a short distance of our respective locations. The two locations are about 16 miles apart. While not record-setting distances, they did offer further field trials of our systems and provided a lot of enjoyment. Both of us set up similar systems using our off-center-feed dish antennas that were originally military 4-GHz antennas. (See Photo A for the off-center-feed antenna mounted with our original GUNN transceiver and small horn aimed at the reflector.)

We removed their feedhorns and replaced them with our homemade 10-GHz transceivers, and used a very small feedhorn to drive the dishes at each end of the path. We were able to make contact on 10 GHz, but I was experiencing very heavy FM broadcast interference on my end. Kerry and I were able to communicate with our systems and had approximately 25 microvolts of signal being received at each end of the path.

It was hard to keep the antennas aimed at each other due to the wind and the lightweight tripods we were using, but we kept in contact. The interference that I was having made the phase-locked detector circuit in the receiver search for a zero-discriminator reading, probably competing with or capturing the commercial FM station. When we were zeroed in, communication was crystal clear, but the slightest movement caused the FM signal to overtake us and destroy our contact.

The transceiver at that time was completely unshielded and open to rf pickup. The ground foil provided a very small measure of protec-



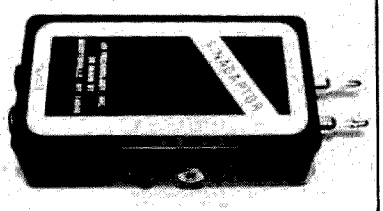


Photo C. Horn-antenna test adjustment range. A suitable distance would be 10–20 feet for small horns.

tion, but in the same area with a high-power transmitter (FM) it wasn't enough. I have yet to enclose my transceiver in a shield. (I'm waiting to find some diecast boxes.)

At the conclusion of our test, I turned off my transceiver and placed the light reflector on the tripod and turned it on in the direction of Kerry on Mount Soledad. He reported a copyable signal, but not what we had expected. I was disappointed, but when the feed was properly tuned I was sure it would perform quite well. I started to pack up. I put the traveling plastic bag over the open end of the feed and taped it into place when Kerry called me on two meters. I had forgotten to turn off my transmitter on 10 GHz, and I was now pegging the meter on his receiver. LIKE, *WOW*, MAN! The plastic bag was providing the required matching and improved the antenna's performance by a factor of 3 to 4 over the previous signal reports.

I removed the bag and the signals dropped. Replacing the bag to the end of the feed did the trick. Studying this new phenomenon, it was learned that what we had accomplished through sheer accident was dielectric loading of the antenna. I was surprised to learn that materials that are very good insulators at VHF and higher turn into something else or at least have a very big effect at microwave frequencies. Enter the black-box theory. Photo B shows the dish and its plastic bag, our dielectric resonator. Fig. 2 shows how a plastic cover can be used to tune a slot antenna, a very good example of dielectric loading. I don't know what I would have done without the *RSGB VHF Handbook* as a reference on this and other topics.

NOW Sinad CAN BE MEASURED WITH YOUR VOM

- *Quickly tune Receivers, Cavities, Preamps, etc.*
- *Works with your VOM or AC VTVM that has 2.5V full scale sensitivity or better.*
- *Fast accurate measurements.*
- *Sinad measurement displayed on meter in "dB" scale.*
- *Self contained, pocket size, go anywhere instrument.*
- *Powered by standard 9V battery or optional AC adaptor.*

Horn Antennas and Feeds

The horn is by itself a feed and also a very good radiating antenna. I am using a very small horn to feed the off-center-feed dish, as shown in the photographs. The horn used is part of the Solfan Intrusion Alarm device that was purchased at one of our local swap meets. The primary advantage in using a horn is its almost perfect match over a wide frequency range and its easy construction. This feed is also very impervious to errors in its construction. A horn is best described as a piece of waveguide with its end flared out, with somewhat the same ratio of width to length. As an example, a horn 6 inches in length with an opening of about 3.5 by 5 inches provides a gain of about 18 dB at 10 GHz. Photo C shows two horn antennas pointing at each other on an antenna test range. Although the distance is much too close as shown here, the operation of test evaluation is the same. The large horn has a detector mount and is coupled to a meter to measure relative signal strength received to tune up systems.

The most expensive part of construction of horns is the waveguide flange used to couple to the waveguide. I have usually purchased scrap pieces of waveguide built for some weird purpose, only to sweat the brased flange off and resue it on another project. Some real nondescript pieces of waveguide with custom bends can be had for very little

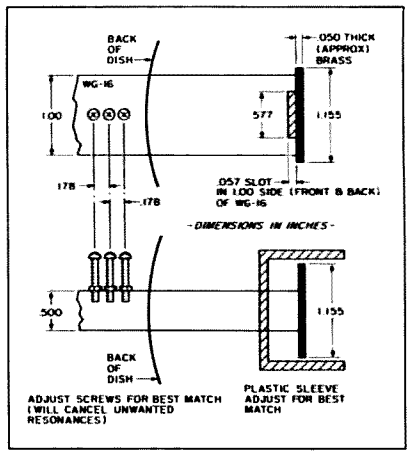

Fig. 2. A slot-feed method for 10 GHz.

money, usually about 75 cents per flange. Remember that if the guide is brass scrap, it is currently selling for about 60 cents a pound—another consideration.

When I sweat the flanges off the waveguide, I place the guide in a vise and let the flange fall into a soft box of sand. Sometimes it is necessary to use gentle tapping to make the flange come off. Do not put the flange in a vise and pull off the waveguide, as you will distort the flange; I found out the hard way. You cannot fix a distorted flange, but you can sell it for 60 cents a pound.

Slot Feed

I have constructed a slot feed that is very easy to make—sort of a one-evening project. A hacksaw, files, and a small piece of brass are all that you need. See the design in Fig. 2 for details. This feed also uses the plastic feed-tuning (dielectric-loading) end-matching device. I have recently built this device, and preliminary testing indicates that its performance is quite good. One word on painting: Cover the slot so that paint does not get into the guide. I usually use a small wood block because it is easily removed after the paint is completely dry. I have found most enamels to be transparent at this frequency. Do not use any paint that has a fleck or a metallic part to its color. I have not tried them, but suspect they will offer some detriment to operation at 10 GHz.

I hope that I have given you some ideas on various feeds that can be made with ordinary hand tools. I do not feel that any special techniques are needed, just a little care in measuring and construction to keep the parts balanced. The construction of these feeds and antennas, when coupled with the transceivers that you have made, should provide many hours of enjoyment. I still delight in the operation on this band and hope that others will have as much fun on 10 GHz as I have.

I will make the 10-GHz GUNN diodes available to amateurs for $5 each postpaid in the continental U.S. These diodes provide an output of 50 to 100 mW; they are about .3 inches long and look like a 4/40 screw without a head. ■

High and Dry

With a little plumbing know-how, WA2OLZ brought his antenna rotator out of the rain and into his attic. (Step 1: Cut a hole in your roof. . .)

How do I get a directional antenna installed in a community that has a building code prohibiting the installation of towers? No doubt this question has been asked many times by hams, but this was my first outing into the world of beam installation vs. the town fathers. The first answer that came to mind was to purchase a short "tripod" tower and mount it on the roof. There were a couple of drawbacks to this scheme, however. First, the town could well give me grief over this solution in that "a tower is a tower," and the tripod could be outlawed. Second, I have heard many horror stories about these mini-towers folding under wind pressure and damaging the roof of the house. This just did not seem to be the answer, and the obvious alternative, a chimney mount, didn't seem appropriate for a three-element triband antenna.

While discussing the problem with me on the local repeater, WA2GFO suggested that if I could somehow mount the antenna on the roof without using a tower at all, the objections of the town would be overcome and I'd have an operable antenna system. The solution was to mount the antenna rotator in the attic with a concentric length of plumber's "black pipe" going through the roof to the antenna. The added advantages of removing the rotator from the harmful effects of the weather and making it accessible from indoors for repairs and adjustment were bonuses—for which I was grateful when the rotator developed a problem when the weather outside was below zero. If the rotator had been mounted outside, it would have been out of service until the following spring. Since it was inside, it was a simple matter to effect repairs in comfort.

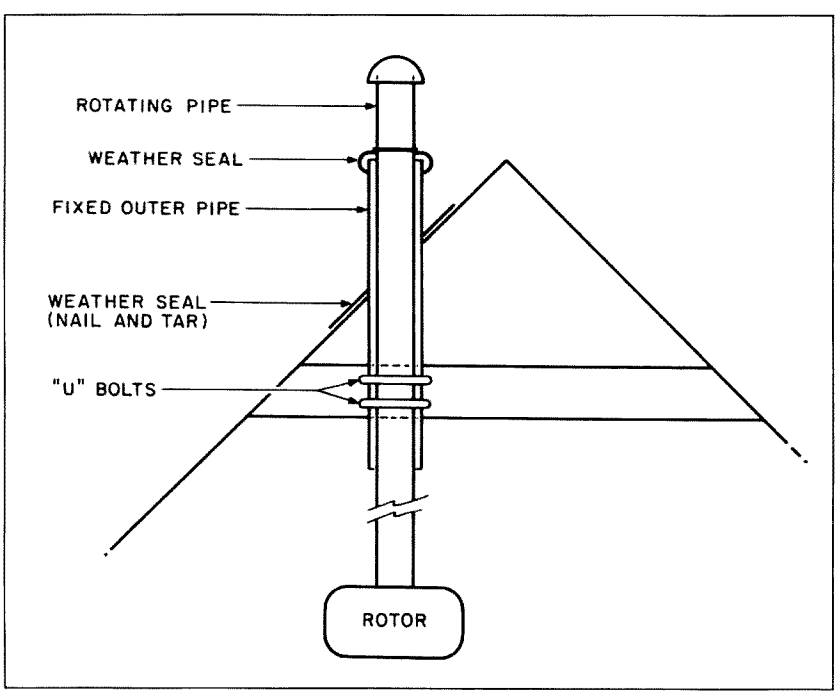

Fig. 1. WA2OLZ's through-the-roof mounting system protects your rotator from the elements and circumvents restrictive tower ordinances.

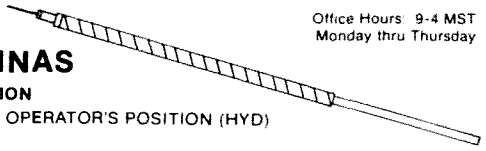
The basis of the installation is to provide a "pipe within a pipe." A hole of the appropriate diameter is cut in the roof by means of a hole saw on a hand drill. The outer pipe is fixed to the roof cross members from inside with U-bolts, and is permitted to extend outside the roof less than one foot. The inner pipe rotates freely within the outer pipe and is bolted to the rotator in the normal manner (see Fig. 1). The original plan called for a thorough application of heavy grease to the inner pipe so that it would rotate smoothly, but this was unnecessary as the pipes are sized such that there is no significant rotational drag.

I was most anxious to ensure that the installation was absolutely watertight—a new roof had been installed on the house the previous year and I had no desire to do that job again! The answer was really quite simple. Every house has a plumbing vent pipe poking through the roof. If I could duplicate the method used to seal this pipe to the elements, there should be no problem with leakage (I hoped). The local plumbing-supply house carried a device with a flexible rubber sleeve mounted to an aluminum plate for just this purpose. The sleeve is designed to provide a weather-tight seal around a vent pipe, and the aluminum plate is secured with roofing nails and roofing tar to the asphalt shingle roof. This was perfect for sealing the outer pipe, but the problem still remained of weatherproofing the small space between the inner and outer pipes.

It so happens that the rubber sleeves are available in various sizes to match the different sizes of "black pipe" commonly used as plumbing vents. So long as the inner and outer pipes are of adjacent sizes, the rubber boot that fits the outside diameter of the inner pipe will also match perfectly the inside diameter of the outer pipe. The top (exposed)



end of the inner pipe was threaded by the plumbing supply house and sealed with a cap designed for this purpose. An additional short length of pipe could optionally be added at this point via a plumbing coupling should it be desired to stack a smaller (2-meter) beam above the primary antenna. This has provided an absolutely weather-tight seal at WA2OLZ through heavy downpours, high wind, and significant snow accumulation.

The very able assistance of N2ESX resulted in the installation of the antenna in only one afternoon. This is definitely not a one-person job! Be certain to observe proper safety techniques and have a safety man in attendance whenever working on the roof.

The antenna is mounted only three feet above the roof in this installation but has generated excellent results including an S9 +20 report from a USSR station in a heavy pileup the first time it was put into service. No doubt even better results could be obtained by using a longer length of inner pipe in order to raise the antenna to a better altitude. I was reluctant to do so, however, for fear of generating excessive side loads on the outer pipe and resultant binding and possible damage to the rotator.

This installation has exceeded my expectations at WA2OLZ and did not incur the wrath of the township powers. In fact, the low height above the roof makes the antenna almost invisible from the street unless you are looking for it. ■

The Ramada Radiator

Build this portable HF antenna using only a Slinky and some PVC tubing—then hit the road.

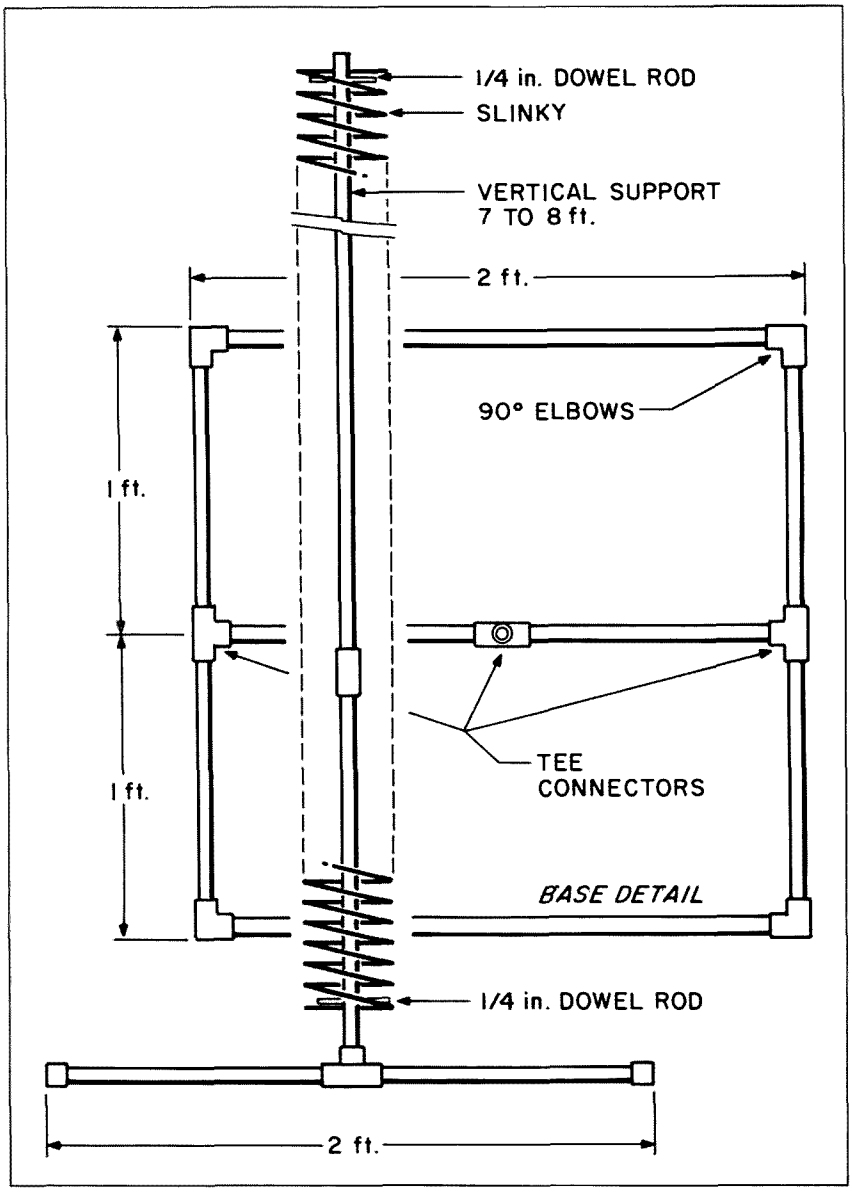

Fig. 1. The Springy portable antenna.

How would you like to have a portable antenna that works like a charm on all the HF ham bands, weighs only a couple of pounds, can be erected anywhere in a matter of minutes, and costs less than $10? Impossible, you say? Well, read on, because the antenna I am about to describe is all that and more.

My job requires lots of travel and I like to operate HF. This can be very challenging and frustrating at the same time. Every new motel room requires a different setup, with much time wasted trying to adjust different lengths of wire with the tuner to find a combination that gives the lowest swr. I enjoy operating QRP CW with an Argonaut and a Century 22, so antenna efficiency is very important. I have tried every type and combination of indoor antenna imaginable over the years, and have found that this little gem works better than most. Best of all, it gives constant loading combinations to my tuner so that I don't have to waste time trying to retune every time I set up.

As you can see, this wonder antenna, the Springy, is built around a toy Slinky™ and two 10-foot lengths of 3/4-inch PVC plastic pipe. You also will need four 90-degree elbows, three T-connectors, and two straight connectors for the 3/4-inch pipe, plus two pieces of 1/4-inch dowel rod four inches long.

Begin construction of the antenna base by cutting one of the 10-foot pipes into two 2-foot and six 1-foot lengths. Construct the base as illustrated in Fig. 1. You do not need to glue any of these joints as they fit very tightly—and once glued, they cannot be taken apart.

Cut the second 10-foot pipe into two 3-foot, one 2-foot, and two 1-foot lengths. Use a combination of these sections to construct the vertical element of the antenna stand. The different lengths of pipe will allow you to vary the height of the vertical element to fit the ceiling height of different rooms.

Drill a 1/4-inch hole through the vertical element at each end. These holes will be used to hold the wooden dowels that support the

Slinky and keep it stretched out. As you can see from the illustration, the Slinky is placed over the vertical pipe and just hangs down.

A tuner will be required to load the Springy. I built mine out of old broadcast variable capacitors and some coil stock I had in my junk box. Any of the smaller commercial tuners will work, but for portable operation, the smaller the better.

With my tuner I am able to load the Springy, with a flat swr, on all bands. I use a small length of wire with an alligator clip at one end to clip onto the bottom of the Slinky. The tuner sits at the base and is connected to the rig via a small length of coax.

I have found the settings on the tuner to be almost the same every time I set the antenna up. There will be slight differences caused by different surroundings, but some minor adjustments are all it takes to get a flat swr. The Springy seems to be broadbanded, and very little adjustment is needed when changing frequencies inside a band.

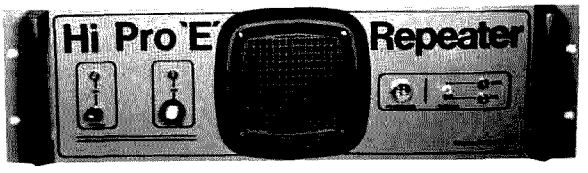
I made a small case from 1/4-inch plywood to carry the plastic stand, Slinky, tuner, and lengths of coax. The first thing I do when arriving at a new location is to set the antenna up, connect the Argonaut or the Century 22, and get on the air. I keep the tuner-setting combinations on a small file card in the box with the antenna. Many times I don't have to do any touch-up at all to get a perfectly flat swr. One point to watch when adjusting for the best swr: Wait until the Slinky has stopped bouncing after you hang it from the vertical stand. The bouncing changes the inductance as the distance between the coils of wires changes, and trying to get a good reading is very difficult, to say the least!

If you are looking for a great little portable antenna to use while on vacation or any time you hit the road, the Springy will do the trick. My first QSO with it was from my kitchen, with a W5 in Texas, on 40 meters. As he gave me an RST of 589—and I was running only about 20 Watts with the Century 22—I knew I had a winner.

"It fits in your pocket, is inexpensive, and if the band goes dead, you can always play with the thing."

I usually carry a small roll of wire with an alligator clip on one end to ground the tuner to the cold-water pipes in the hotel room. This seems to help my signal get out and at the same time makes the Springy more broadbanded.

If you are the adventurous type who likes to operate portable outdoors, give the Springy a try by hanging it from a tree limb with a rope. I've found it works very well suspended about 10 feet above the ground. Drive a stake into the ground directly under the antenna and tie a piece of string or other nonconducting material to it to keep the Slinky taut. Load it from the bottom as you would any vertical.



The little Springy antenna works great outdoors or in, so give it a try the next time you need a portable, allband antenna. It fits in your pocket, is inexpensive, and if the band goes dead, you can always play with the thing.

I should include one word of caution concerning the use of this antenna. Its use does tend to attract attention, especially when hung from a tree in public camping areas. If being stared at and having your sanity questioned by everyone in camp bothers you, don't use this antenna. If having people suddenly grab their children by the arm when within 50 yards of you and moving them to the other side of the park disturbs you, don't use this antenna. But—if you want to have fun on the air from just about any location, give the Springy a try. After all, most people thought Marconi, Edison, and the Wright brothers were a little strange, too, so you are in good company! ■

The Texas Tango Antenna

Ticked off at traps, K5BTV stumbles onto a 75/40m tuned-stub dipole.

Over the years I've tried many types of antennas for 75 and 40 meters. These have included verticals, folded dipoles, inverted vees, and trapped antennas—plus a few that still defy description. Several common requirements have emerged through this work: The antenna has to be confined within my property line (90 feet x 120 feet) and the wires kept to a minimum to keep the neighbors and XYL at bay. But most importantly, the antenna has to perform well.

The addition of the WARC bands presented a new challenge. Until I could develop a suitable yagi to cover the bands above 40 meters, a trapped inverted vee seemed the best way to become active on the new bands. So a three-band trapped inverted vee was constructed to cover 75, 40, and 30 meters using coaxial-cable coils on PVC tubing.

The trapped inverted vee was erected at 40 feet on my tower. On 75 meters, the operating frequency limit to stay within a 2:1 swr was approximately 50 kHz; on 40 and 30 meters it was about 25 kHz. The coil-and-capacitor trap impedance is responsible for the bandwidth of each band, as described in an article by John Grebenkemper (*QST*, May, 1985). But having already constructed the antenna, I knew I would have to construct new traps if I desired more bandwidth.

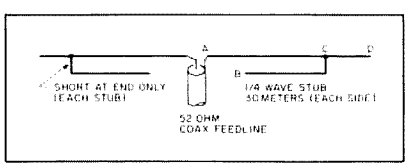

Fig. 1. Quarter-wave stub traps on a half-wave dipole. For a 75/30-meter antenna, the distance from A to D = 234/3.825 = 61 feet. The distance from A to B = B to C = 234/10.115 = 23 feet.

While enjoying the patio and thinking about the disadvantages of the coaxial traps (moisture penetration, arcing of the capacitor, added weight, etc.), I thought about an old TVI-prevention scheme that used a tuned stub to trap out the offending signal. Then the idea came to light. Since a quarter-wave section of feedline that has been shorted at one end and is open at the other exhibits an infinite impedance at the open end—perfect for a trap—why not use quarter-wave stubs for traps? Some further thought provided the final solution: Make the 75-meter leg of an inverted vee part of a quarter-wave stub for 30-meter operation.

Fig 1. shows the mechanical layout. At my station, I use separate 40- and 75-meter antennas fed from a single 52-Ohm coax feedline. The 40-meter antenna is broadside to the north, allowing me to keep schedules with my dad (W0IMZ) while the 75-meter inverted vee is used for contacts east and west of my QTH. The object was to end up with two antennas that could operate on 75, 40, 30, and 12 meters using one 52-Ohm feedline.

Construction of the antenna was surprisingly simple, as was the adjustment. First the 75- and 40-meter inverted-vee antenna elements were erected using #14 copper wire obtained from the local hardware store. The antennas were then resonated at the frequency of interest on each band. The 75-meter antenna was to carry the 30-meter stub, and the 40-meter antenna the 12-meter quarter-wave stub. Since the construction of both antennas uses the same principles, this discussion will cover 75/30-meter elements.

From the feedpoint on the 75-meter leg, measure out a quarter wave using the *Radio Amateur Handbook* equation L(feet) = 234/f (MHz). For 30 meters this is L = 234/10.115, or 23.1 feet. Therefore, from the feedpoint, measure out 23.1 feet. This is the point at which the open end of the 30-meter stub begins. You may want to wrap a piece of masking tape on the 75-meter leg to mark the spot for future reference. From this spot, lay out the 23.1-foot wire beneath the top wire. At the end of the quarter-wave stub, it will be necessary to short the wire to the top 75-meter section. I used alligator clips so I could tune the stub before I soldered the connection. To complete the stub, you must use spacers for the wires. Radio Shack has

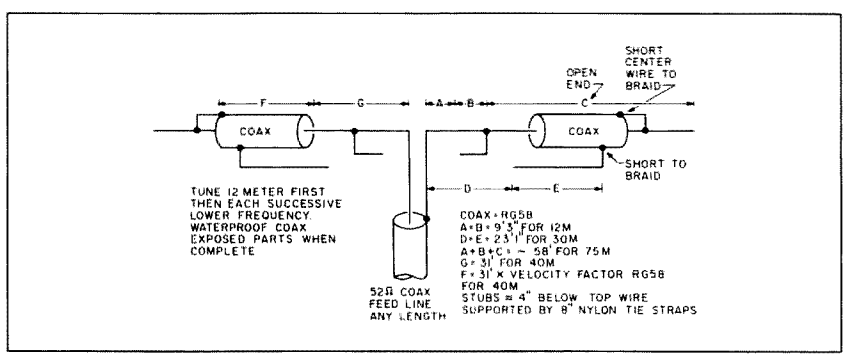

Fig. 2. Single-wire antenna for 75, 40, 30, and 12 meters (untried, but it should work).

6-inch nylon cable ties that work well for spacers. Simply loop them around the two wires and pull the tie to the first notch, locking it. This results in approximately a 3-inch spacing. The wire size and spacing result in approximately a 600-Ohm quarter-wave stub. Wooden dowel spacers could also be used.

An alternative to the construction as discussed above would be to use 300-Ohm twinlead or commercial open-wire twinlead. Simply use one leg as the top element of the 75-meter antenna. An advantage of twinlead is that it can be cut to approximately one-quarter wavelength, shorted at one end, and resonated using a grid-dip meter while on the ground. Then one side of the wire can be used as the top-wire element for the 75-meter antenna.

Once the mechanical details have been worked out, final-tune the 30-meter stub—either by moving the alligator clip toward the feedpoint an inch or two at a time if the resonant frequency is too low, or by moving the shorting alligator clip to the far end if the resonant frequency is too high. A final check of the 75-meter band will now be necessary because of the effects of the lower wire. Once the antenna is resonated, you may want to solder the end of the stubs to the top section to complete the job. You are now ready for some fun operating.

"I thought about an old TVI-prevention scheme that used a tuned stub to trap out the offending signal."

Operation of this antenna has met the expectations set for it. Tuning the 75-meter band from the low-frequency point to the high-frequency point provided a vswr of 2:1 or better over 4.4% of the band, which was almost the same when the 75-meter inverted vee was used alone. The 30-meter operation covered the entire 30-meter band with less than a 2:1 vswr. It measured about 2.2% of the resonant frequency. These percentages seem to agree with the expectations derived from the *QST* article.

This antenna offers some advantages over coil/capacitor trapped antennas. It eliminates the need for high-voltage capacitors. It also can handle the full, legal power limit, is easy to construct, and provides wide bandwidths on each band. There are several other methods that should prove satisfactory whereby quarter-wave traps could be constructed. Although I've not tried it, a single, full-size wire antenna could be made for 75, 40, 30, and 12 meters using a combination of coax quarter-wave stubs and open-wire quarter-wave stubs (see Fig. 2). I would like to hear from others who may try these ideas. 73 and good operating over more of our bands. ■

Trap An Amazon Aerial

Build your own capacitors and trap-tune your dipole for multiband operation.

A trap-tuned dipole can make a very satisfactory multiband antenna, but building it can be a real headache! My first attempt to build a trapped antenna, in 1970, resulted in dismal failure (which explains my formerly held low opinion of them). I must have learned something since then, for I now have several trap-tuned dipole antennas giving excellent service in a commercial radio communications net that I help maintain.

Perhaps among the readers of this magazine there is someone else who has been frustrated in an attempt to use traps in an antenna. If so, you may benefit from a discussion of the design procedure I followed.

I needed several antennas for use with 20-Watt transceivers operating on 6.954 MHz and 5.710 MHz. These made up portable stations carried by research teams working in the Amazon jungle. Our licenses limited us to dipole antennas, but for portability I didn't want to send two antennas with each station. In addition, since the antennas would be carried as baggage and would be erected by untrained personnel, I didn't want them to be either heavy or complicated. What resulted was a relatively lightweight, rugged dipole antenna that gives less than a 2:1 vswr at both frequencies.

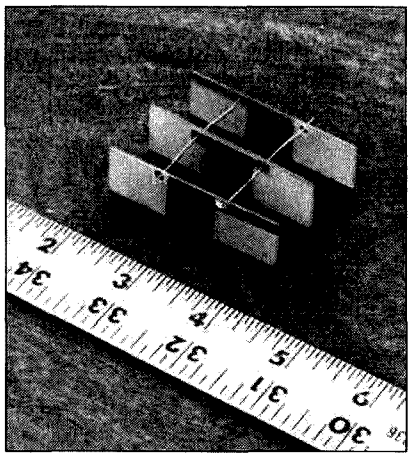

Photo A. Capacitor assembly strung on jumper wires; ready to be glued together.

The Trap-Tuned Dipole

A trap-tuned dipole for two frequencies is shown in Fig. 1. The inner antenna is cut for the higher operating frequency. Traps that are parallel-resonant at the higher operating frequency separate the inner antenna from extensions. The high impedance shown by the traps isolates the inner antenna from the extensions when the higher frequency is being used. Below resonance, the traps appear to be inductors connecting the extensions so that the overall antenna is active at the lower operating frequency.

Inductors and capacitors are reactive elements. That is, they react to alternating current to show a frequency-dependent opposition to current flow. The Ohmic values of inductive and capacitive reactances are calculated using Equations 1 and 2, respectively. These reactances are, you might say, of opposite characteristics, though both are measured in Ohms.

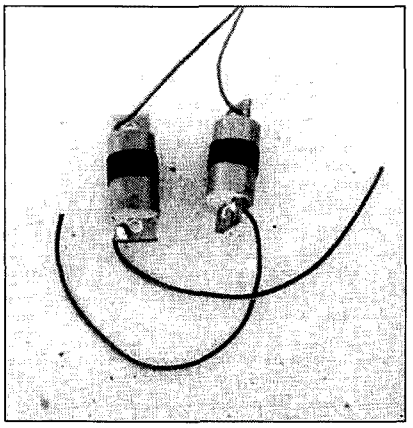

Photo B. Completed traps.

For a complete treatment of these reactances, phasor algebra is employed. I won't go into that. Suffice it to say that strange things happen in circuits containing both inductive and capacitive reactances.

Equation 1: $X_L = 2\pi fL$

Equation 2: $X_C = 1/(2\pi fC)$

where L is the inductance in Henrys, C is the capacitance in Farads, f is the frequency of operation in Hz, and X_L and X_C are in Ohms.

As you can see from these equations, inductive reactance increases and capacitive reactance decreases as frequency increases. A circuit containing an inductor and a capacitor will have both inductive reactance and capacitive reactance. At some frequency, those reactances are equal and cancel, resulting in the phenomenon called "resonance." When the reactances are in series, this cancellation results in a low impedance. When the reactances are in parallel, the result is a very high impedance, which is the characteristic that makes a trap-tuned antenna possible.

Equation 3, giving the relationship between L, C, and resonant frequency, shows that virtually any inductor can be made to resonate at any frequency by selecting the proper capacitor.

Equation 3: $f_r = 1/(2\pi\sqrt{LC})$

where L is inductance in Henrys, C is capacitance in Farads, and f_r is the resonant frequency in Hz.

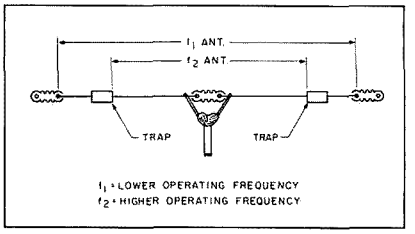

Fig. 1. Trap-tuned dipole antenna.

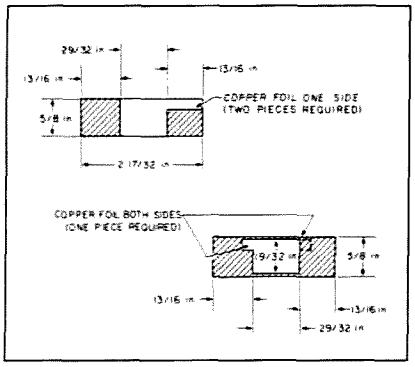

Fig. 2. Plates for 50-pF capacitor assembly.

F (MHz)	C (pF)	L (uH)	L/C

Table 1.

This indicates that traps can be built using a wide range of values, but there are some practical considerations. The relationship of L and C to the resonant impedance of the trap is shown in Equation 4.

Equation 4: $Z_t = L/(CR)$

where L is inductance in Henrys, C is capacitance in Farads, R is the resistance of the inductor in Ohms, and Z_t is the resonant impedance in Ohms.

As L is increased and C is decreased, Z_t increases. A high L/C ratio would seem to be best in order to ensure that the trap will show a high impedance at resonance. However, the physical size of a large-value inductor imposes some limitation, as does the difficulty of using extremely small values of capacitance. It is necessary to strike a compromise.

At the frequency I used, 6.954 MHz, I found that a 10-uH inductor and a 50-pF capacitor give good results. Their impedances are about 460 Ohms and their L/C ratio is around 200,000. From Equation 4 we find that the parallel-resonant impedance of these components will be over 200k, even if the dc

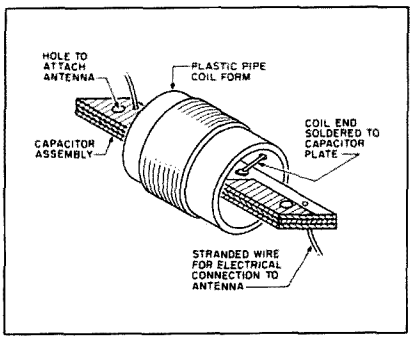

Fig. 4. Trap assembly.

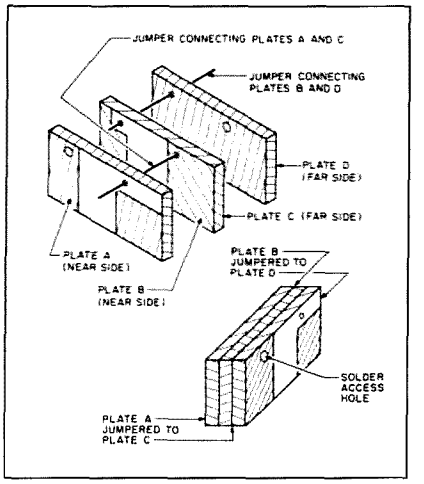

Fig. 3. Capacitor assembly detail.

resistance of the inductor is as high as 1 Ohm. It is reasonable to expect less than 1 Ohm of resistance in the coil, so these were the component values I selected.

I calculated the capacitances required at various frequencies for an impedance approximately equal to the impedance presented by the 50-pF capacitor at 6.954 MHz. I then used Equation 5 to calculate the inductances required to resonate the capacitors at those frequencies, and verified that the L/C ratio was at least 200,000.

Equation 5: $L = 1/(4\pi^2 f^2 C)$

where f is the desired resonant frequency in Hz, C is the capacitance in Farads, and L is the inductance in Henrys.

Table 1 gives the component values used and shows the L/C ratios.

The Capacitors

I decided to deal first with the capacitors, since inductors are relatively easy to adjust to a desired value. I experimented with both molded mica and dipped silver-mica capacitors. (Admittedly, this was possible only because I was working with low power. For higher power, special transmitting capacitors are needed.) The silver-mica type produced good results, but I didn't have enough of them to make all the antennas I needed. Being somewhat reluctant to spend money needlessly, I decided to try building

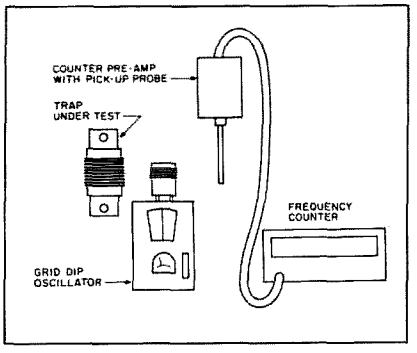

Fig. 5. Test setup.

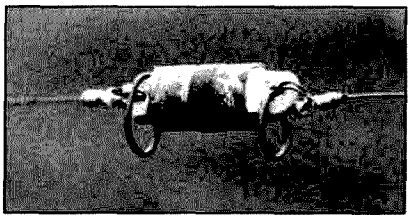

Photo C. Trap installed in antenna.

my own capacitors. Why buy when you can build?

Double-clad, glass-epoxy printed-circuit-board stock seemed a good choice of material since I had some on hand, but before becoming too deeply committed to this project I wanted to determine the feasibility of using this material for these capacitors. I didn't want to build a capacitor that would make the traps so large that the antenna would not fit the shipping container!

Capacitance is relatively easy to relate to size, but the equations invariably call for the dielectric constant. Since this figure was not available to me, I determined it by measuring the capacitance of one square inch of the board material and comparing it with the calculated capacitance of an air-dielectric capacitor of the same dimensions. (I used a capacitance meter built following plans in an amateur magazine, so this isn't really an exotic piece of equipment.)

The measured capacitance was 30 pF/square inch. The capacitance with air dielectric was calculated to be about 5.1 pF, using Equation 6.

Equation 6: $C = 0.2249 \times (kA/d) \times (n - 1)$

where C is capacitance in pF, A is the area of one plate in square inches, d is the distance

Photo D. Feedline protection using the PY8ZAC/W8VOH method.

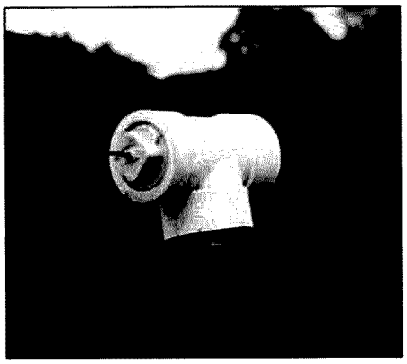

Photo E. Feedline protection using plastic pipe fitting.

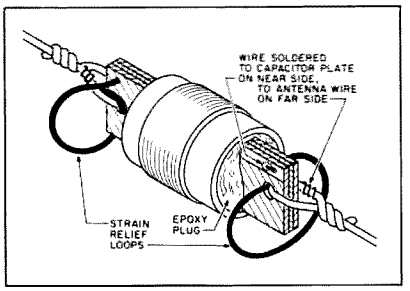

Fig. 6. Connecting the trap to an antenna.

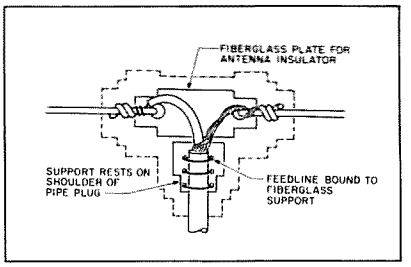

Fig. 7. Interior view of the plastic pipe fitting showing antenna feedpoint assembly.

separating the plates in inches, n is the number of plates in the capacitor, and k is the dielectric constant of the insulating material (30 pF/5.1 pF = 5.9).

Using Equation 6, with k = 5.9, I found that the required plate area for a two-plate, 50-pF capacitor is approximately 1.6 square inches. That was a bit larger than I wanted. One more pass through the equation showed that a 4-plate, 50-pF capacitor required a plate area of only 0.56 square inches, which seemed much more reasonable for my application. The calculated dimensions and number of plates for the capacitors are shown in Table 2.

I built the 50-pF capacitors using plates measuring 5/8" x 29/32", prepared by cutting the copper foil on three pieces of board material as shown in Fig. 2. The copper on one side of two of those pieces was cut so as to center the plate area and leave a finger extending to one end of the piece, while the copper was removed from the other side. A single piece was prepared with a plate on both sides, each with a finger extending 3/16" toward an end, such that they could be assembled as shown in Fig. 3.

The copper foil of each single-sided piece is on the outside and the double-sided piece is in the middle. The fingers on the outer pieces, plates A and D, point toward opposite ends. The fingers on plates B and C are oriented the same as the fingers on plates D and A, respectively. I used epoxy to glue all the pieces together.

Access holes drilled for this purpose allowed jumpers to be soldered to connect the fingers on the inner piece with the corresponding fingers of the outer plates to form a 4-plate capacitor. I then trimmed the capacitor to measure precisely 50 pF by cutting thin strips of copper from the exposed plates. The glass-epoxy board pieces are long enough to extend beyond the area used for the capacitor so that they can be used to attach the antenna. The same procedure was used for the other capacitors, using the dimensions given in Table 2.

The Inductors

As shown in Fig. 4, I glued each rectangular capacitor into a piece of 5/8" plastic pipe, which also served as a form for the trap's inductor. Table 3 lists the inductors required to resonate the capacitors previously chosen for use at the selected frequencies. To calculate the approximate number of turns of wire required for each, I divided the inductance per inch of the proposed coil into the desired inductance and multiplied the quotient by the turns per inch. The inductance per inch may be found from Equation 7.

Equation 7: $L = (nr)^2/(9r + 10l)$

where L is inductance in uH, l is the length of the coil in inches, r is the mean radius of the coil in inches, and n is the number of turns in the coil.

For my low-power use, I felt safe using a close-wound coil, so n was based on the turns-per-inch specification from the wire tables. From Equation 7, I found that #26 wire close-wound (58 turns per inch), 1 inch long on a 13/16" form (the outside diameter of 5/8" plastic pipe) will have approximately 39 uH of inductance. Dividing the desired inductance, 10.5 uH, by 30 uH and multiplying by 58 turns per inch indicated that 16 turns would be required (see Table 3).

I then checked my figures by calculating the inductance of 16 turns of #26 wire close-wound on a 13/16" form and found it was only 6.5 uH! Apparently the relationship is not linear. By this kind of repetitive calculation, I determined that 22 turns will produce approximately 10.5 uH.

With the capacitor assembly glued in place inside the coil form, I wound the calculated turns of wire plus about 10% onto the plastic pipe and soldered the ends to the capacitor. Using the test setup shown in Fig. 5, I measured the resonant frequency of the trap. As expected, it resonated at a lower frequency than I wanted, so I removed wire a bit at a time until the trap resonated at the desired frequency. The exact number of turns required varied slightly depending on the actual value of the capacitor, so I was careful always to start with extra turns in the coil. Generally, I have more success shortening a wire than I do lengthening it!

The Antenna

When the traps were built, I sealed the ends of the coil forms using epoxy putty and coated the entire assembly with regular epoxy to secure and protect the coil. Wires soldered to the fingers of copper foil on the capacitor pieces are used to connect the traps to the antenna.

The antenna was built following the pattern of Fig. 1. The inner antenna was cut for the higher frequency, f2, according to the length calculated using Equation 8.

Equation 8: $l = 468/f$

where l is the antenna length in feet and f is the operating frequency in MHz.

For 6.954 MHz, the inner antenna was 67' 4" long. At that frequency, the traps are intended to serve as insulators. Returning to Equation 4, we can calculate the theoretical impedance of these traps at resonance to get an idea of their effectiveness for this purpose.

The 10-uH inductor required 4.25 feet of #26 wire, which has about a 0.04-Ohm resistance per foot, so R will be 4.25 x 0.04 Ohms, or 0.17 Ohms.

Applying Equation 4, we find:

$$Z_t = L/(CR)$$
$$= 10.5 \times 10^{-6}/(50 \times 10^{-12} \times 0.17)$$
$$= 1.24 \times 10^6 \text{ Ohms}$$

That is 1.24 megohms, which should isolate the inner antenna adequately at the higher frequency. This impedance could be increased by using larger wire for the inductor so as to have a lower value of resistance in the coil.

At 5.710 MHz, the traps exhibit 560 Ohms of capacitive reactance and only 370 Ohms of inductive reactance, so the antenna current will flow mostly through the inductor. This inductance will tend to electrically lengthen the antenna, so its physical length will be somewhat shorter than its theoretical length. It probably would be possible to calculate this, but I just used the theoretical length of antenna for the lower frequency and trimmed the length until the vswr was acceptably low. When the total antenna length was 75' 5", the vswr at 5.710 MHz was approximately 1.8:1 and at 6.954 MHz was 1.5:1. As the theoretical length of antenna for 5.710 MHz is 81' 11.5", this means the traps reduced the low-frequency antenna to about 92% of its theoretical length.

The characteristics of these traps are predictable and the results are repeatable. Being the pessimistic type, I built each antenna a bit long at first and trimmed it. However, as I gained confidence, I began cutting them to

C (pF)	Plate Area (sq. in.) 2-plate	4-plate	Capacitor Used (see text)
50	1.6	0.56	4 plates, 5/8" x 29/32"
47	1.5	0.52	4 plates, 5/8" x 27/32"
24	0.78	0.27	4 plates, 1/2" x 9/16"
16	0.52	0.18	2 plates, 5/8" x 27/32"
12	0.39	0.13	2 plates, 9/16" x 23/32"

Table 2.

L (uH)	Coil on 3/16" Form
10.5	22 turns #26, close-wound
10.4	21-3/4 turns #26, close-wound
5.16	13-3/4 turns #26, close-wound
3.5	11 turns #26, close-wound
2.65	9-1/4 turns #26, close-wound

Table 3.

the same measurements as the prototype without allowing extra for trimming. All of these measured less than a 2:1 vswr at both operating frequencies.

Ensuring Durability

Since these traps were used as the mechanical support of the antenna, I was concerned that they might not be strong enough to withstand the pull. As a crude test, I tied one about 10 feet up on an antenna tower and stood in a loop of wire attached to it. It supported my weight (190 lbs.), so I concluded that the antenna wire would break before the traps would.

One weak point in this antenna is the connection of the traps to the antenna wires. Since the antenna sways in the wind and is taken down periodically, the trap connections are subject to flexing. I have had good success in reducing the effects of that flexing by making the connections using a strain-relief loop, as shown in Fig. 6. In the event that a connecting wire does break, another wire can easily be soldered to the finger of the capacitor plate without disturbing the epoxy plug in the end of the coil form.

Another weak point on any wire dipole antenna is the fact that the feedline is open at the top. If water enters the feedline, it will cause the line to deteriorate, and may even run out at the bottom end making a puddle where you least expect it!

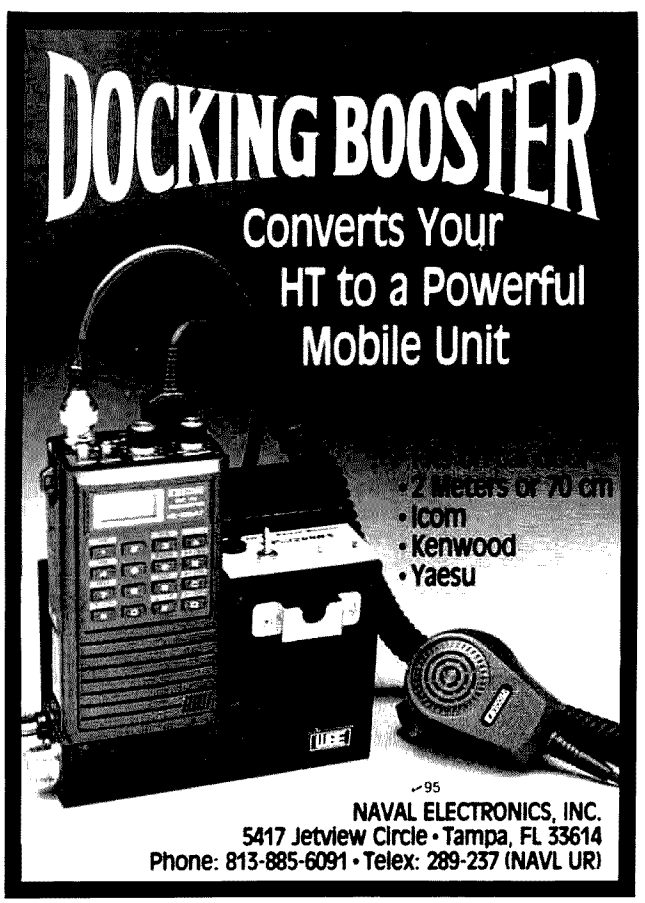

Photo D shows one solution to this problem—as described in *73* almost 10 years ago by PY8ZAC/W8VOH. The loop in the coaxial cable keeps the open end pointing down so rain will drain away from it. Sealing the open end with epoxy or a *noncorrosive* silicone rubber will provide additional protection. (Note that the silicone rubber preparations that smell like vinegar will cause corrosion.)

Photo E shows a more elegant way to weatherproof the center feedpoint. A plastic pipe T connector encloses the antenna feedpoint assembly (Fig. 7). The holes in the three pipe plugs, through which the wires and feedline pass, are sealed by means of epoxy or noncorrosive silicone rubber.

Conclusion

I have found the performance of these antennas to equal that of regular dipoles while occupying less space and weighing less. In addition, they cost less. The epoxy seal has held up well even with the rains we experience in the tropics. The only antenna I have had to repair, of the ten I have in use, is the one that broke when a strong wind caused the supporting tree to sway more than we expected. The antenna wire broke, rather than the trap, so this confirmed the results of my crude weight-bearing test.

It's a pity I "grow too late smart"! These antennas could have saved me lots of work over these past years! ■

Resonant Wire Antennas

You may not believe it, but you can build a working antenna without the crutch of coax!

More often than not, homemade antennas perform better than store-bought ones. This is because most commercially-manufactured systems are designed primarily so that they can be fed with coaxial cable. Performance is only a secondary consideration.

Coaxial cable is neat stuff and is convenient to use. But, it's expensive, and, although a few amateurs think that *all* antennas are fed with coaxial cable, it's the worst kind of feedline to use if the antenna is to work effectively on several amateur bands.

How would you like to have an antenna that works well on several bands and one that has *no* feedline loss? Impossible, you say? Not at all. You can build an antenna that has no feedline, and therefore no feedline losses. Simply use the following principles in your design:

1. A half-wave resonant antenna (dipole) has high rf *voltage* at its ends and high rf *current* at its center (see Fig. 1).

2. The length in feet of a half-wave resonant antenna is 468 divided by the frequency in megahertz (L = 468/f).

3. An antenna that is a half wavelength long for a low band (such as 3.5 MHz) is also resonant at harmonics of the lower bands and has high rf voltage at its ends. Harmonics of 3.5 MHz are 7, 14, 21, and 28 MHz (see "Harmonics" sidebar).

4. In tuning a coil and capacitor to resonance at a given frequency, parallel tuning is used to provide *rf voltage*, which is needed to feed the end of a resonant-length antenna.

5. Link coupling can be used to take rf from the transmitter into a parallel-tuned inductor, one end of which is connected to the end of a resonant-length antenna. The other end of the parallel-tuned coil is connected to the grounding system (see Fig. 2). The rf energy, in the form of voltage, goes into the antenna wire and is radiated.

As with other types of antennas, the parts of the antenna that have the greatest amounts of rf current in them should be as high and in the clear as is possible. Supporting a wire vertically would put the rf current part of the antenna as high as possible (see Fig. 3). Half-wavelength vertical antennas work well and are practical on the higher bands. They provide the low-angle radiation needed for working DX.

Antennas do not have to be supported in a straight line. Inverted vee, inverted L, or other configurations can be used. W8BVU once had an antenna the top of which was taped to a bamboo fishing pole. The wire had several curves going from the antenna tuner up to the bamboo pole. W8BVU called it the Chinese Snake Antenna.

For protection against lightning damage, a means of grounding the antenna when it is not in use should be provided outside of the building (see Fig. 4). Note the SPDT switch and the separate earth ground used for this lightning protection.

Two circuits for an antenna tuner to provide rf voltage to feed an endfed resonant-length wire are shown in Fig. 5. The variable capacitor in series with the primary coil (L_1) is helpful in reducing the swr between the transmitter and the antenna tuner. Plug-in coils can be wound on plug-in coil forms or

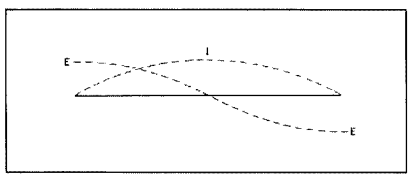

Fig. 1. Rf voltage and current distribution on a half-wave resonant antenna.

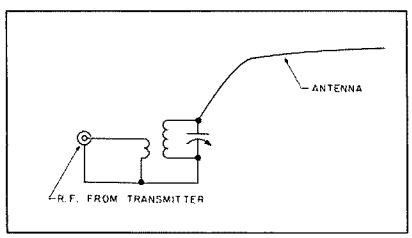

Fig. 2. Feeding rf voltage *to the end of a resonant antenna (parallel-tuned coil to give rf voltage).*

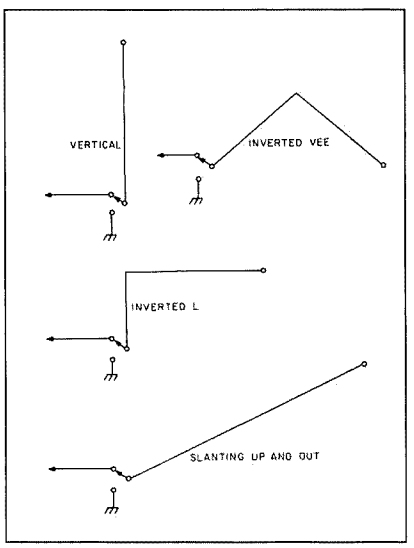

Fig. 3. Some endfed-antenna configurations.

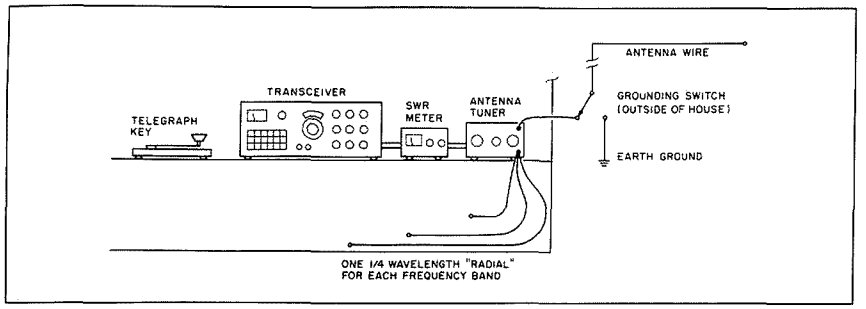

Fig. 4. Protect your station against lightning damage with a grounding switch mounted outside of the house.

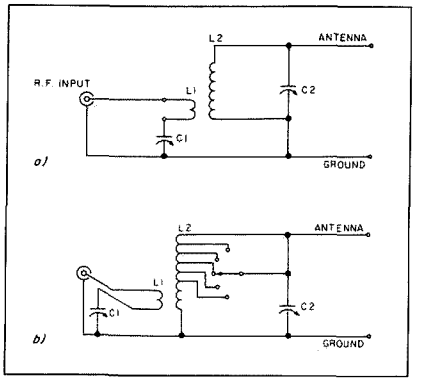

Fig. 5. Circuits of simple tuners suitable for feeding rf voltage to one end of a resonant-length antenna wire. The tuner in a) utilizes plug-in coils, while the circuit shown in b) uses a more convenient tapped coil. (These tuners will not *work with a random-length antenna wire.)*

on the bases of burned-out tubes, sometimes made longer with cardboard tubing. It's not necessary to have a coil for each band. One coil would cover 1.8–4 MHz, another 7–10.15 MHz, a third 14–21.5 MHz, and the fourth 21–30 MHz. For best results, the parallel-tuned coil and capacitor combination should have a relatively large inductance tuned to resonance by a relatively small capacitance. (See the sidebar on coils and capacitors.)

Those of us who have an antenna tuner with a single-wire terminal can easily try out an antenna that does not have a feedline. We can string up a random, but reasonable, length of wire as high as possible, bring one end into the shack, connect it to the single-wire terminal of the antenna tuner, load it up, and go on the air.

A good grounding system (sometimes called a "counterpoise") connected to the ground post of the antenna tuner is a *must* when you're using any endfed antenna. Such a grounding system can be made by connecting quarter-wavelength wires to the antenna tuner's ground post (one wire for each band on which the antenna is to be used). Table 1 gives quarter wavelengths of commonly used bands. The far ends of these wires should be taped with electrician's tape because they might be hot with rf when the rig is transmitting.

These wires can be located inside the house, running along the baseboards of rooms (for example), or they can be run outside of the house near the ground. These radials help prevent rf-in-the-shack problems and equipment hot with rf. (William I. Orr W6SAI and Stuart D. Cowan W2LX, in their book, *Simple Low-cost Wire Antennas*, have an excellent chapter on endfed antennas: Chapter 8, "The End-Fed, Multi-Band Antenna." This chapter emphasizes the importance of ground radials and describes a simple L-net antenna tuner for use with endfed antennas. This book is one of the best in my antenna library.)

1.8 MHz	120 to 130 feet
3.5 MHz	63 to 66 feet
7 MHz	32-1/2 to 33 feet
10 MHz	21 to 22-1/2 feet
14 MHz	16 to 17 feet
21 MHz	11 to 12 feet
28 MHz	8 to 8-1/2 feet

Table 1. Quarter wavelengths for each band.

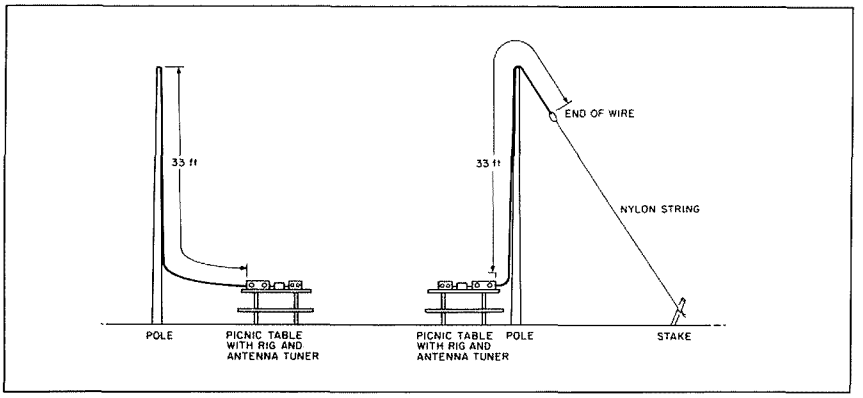
An important characteristic of endfed antennas is that they can be used on several bands. Such antennas should be at least a quarter wavelength long for the lowest band on which they will be used. For example, an antenna for the 3.5–4-MHz band and higher bands should run at least 65 feet, and 90 to 100 feet would be even better.

A good length for bands 14 MHz and higher would be 45 to 50 feet. Such an antenna would work also on the 7- and 10.1-MHz bands. For gain in the direction of the wire on the 14-MHz and higher bands, the endfed antenna should be several hundred feet long—the longer the better.

Loading the Endfed

The output of the transmitter (transceiver) goes through the swr meter into the antenna tuner's input. The endfed antenna is connected to the single-wire terminal of the antenna tuner (see Fig. 4). Using low rf power from the transmitter, carefully adjust the inductance and variable capacitance of the antenna tuner for the greatest amount of forward power with the least amount of reflected power. (Follow the directions that came with the tuner.) It will be possible to find settings on the tuner that will result in much forward power with little or no reflected power.

After you've made these adjustments using low power, the rf power output of the trans-



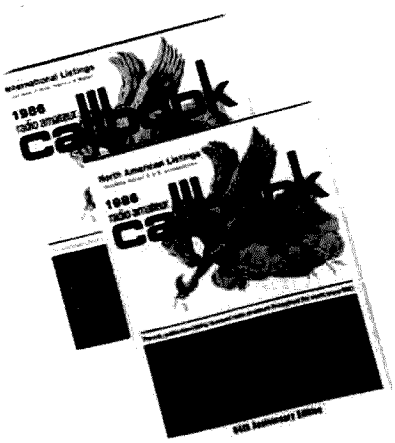


Fig. 6. Twenty-meter vertical resonant-wire antennas.

HARMONICS

Harmonic frequencies of an antenna of a given length are not exact multiples of the fundamental frequency. They are higher than the fundamental frequency multiplied by the number of the harmonic. For example, the second harmonic of an antenna length that is a half wavelength long at a frequency of 3510 kHz is greater than 7020 kHz. This is because there is less "end effect" on the harmonic frequencies. (See the 14th edition of the ARRL *Antenna Book*, p. 2-7, "Length of a Harmonic Wire.") Therefore, it is a good idea to make a resonant endfed antenna the correct length for a frequency near the low end of the lowest band on which the antenna is to be used. This is so that its harmonic frequencies will not be too high. The antenna tuner provides some adjustments for the higher frequencies of the lowest band to be used, and on the harmonic bands of the antenna.

1986 CALLBOOKS

The "Flying Horse" has a great new look!

It's the biggest change in Callbook history! Now there are 3 new Callbooks for 1986.

The North American Callbook lists the amateurs in all countries in North America plus those in Hawaii and the U.S. possessions.

The International Callbook lists the calls, names, and address information for licensed amateurs in all countries outside North America. Coverage includes Europe, Asia, Africa, South America, and the Pacific area (exclusive of Hawaii and the U.S. possessions).

The Callbook Supplement is a whole new idea in Callbook updates. Published June 1, 1986, this Supplement will include all the activity for both the North American and International Callbooks for the preceding 6 months.

Publication date for the 1986 Callbooks is December 1, 1985. See your dealer or order now directly from the publisher.

mitter should be increased to the desired level and the dial settings of the variable capacitors touched up a bit to get rid of any reflected power that may be present. *With rigs that have tube output stages, the "plate-tune" control should be checked and the plate current "dipped" to the lowest amount.* The rig will then be ready to go on the air and make contacts.

On the Road

Endfed antennas are especially good for portable use. Amateurs who like to take their radio equipment with them on camping trips can use endfed antennas to good advantage. For example, at a weekend camp-out in a northern Michigan trailer camp, W8BVU put his receiver, transmitter, and antenna tuner on a picnic table. Using an endfed 33-foot antenna wire supported vertically by some light lumber and a long fishing pole, he had his usual Saturday-morning schedule with W7WV in Scottsdale, Arizona. In June, 1985, I set up a QRP station in a cabin in Colorado. With a 67-foot endfed antenna and 6 Watts of rf, I joined my regular Tuesday-evening net and worked stations in St. Louis, Missouri; Dickinson, Texas; and Silver City, New Mexico.

It's fun to take a small battery-operated transceiver on picnics; an endfed antenna is ideal for this activity. It's not difficult to hold up a 20-meter vertical antenna (33 feet) if a telescoping 20-foot fiberglass fishing pole is available. The pole can be mounted on top of other lightweight bits of lumber, and excess length can be accommodated by mounting the pole some distance from the table and running the wire horizontally for the necessary distance. Excess wire also can be attached to a piece of nylon string and run out and down from the top of the pole—fasten the string to a stake driven into the ground (see Fig. 6).

For the lower bands, the light wood and fishing pole combination could be used to hold up the center of a longer endfed wire in the form of an inverted vee.

It would be fun to use as an endfed antenna a piece of fine wire suspended vertically from the string of a high-flying kite. Marconi communicated across the Atlantic Ocean with a kite-supported antenna. Perhaps you could, too!

If you have never done so, you owe it to yourself to try an antenna that has no feedline losses. Get the high rf part (or parts) of the antenna way up in the air and enjoy the good QSOs that it will provide on two or more bands. It might be the best antenna that you ever had. ■

ENDFED ANTENNA TUNER COIL AND VARIABLE CAPACITOR INFORMATION

(Resonant-Length Wires Only)

C_1 is a two- or three-gang broadcast band variable capacitor with all of its stator sections connected in parallel.

C_2 is a variable capacitor with wide enough spacing between its plates to withstand the rf voltage that will be applied to it without arcing. Its value should be at least 100 pF. A vernier dial on this capacitor helps in making fine adjustments.

Plug-in coil data:

Frequency Range	L_1 Turns	L_2 Turns	Diameter of Coil Form
1.8 to 4 MHz	5	35	1-1/2 inches
7 to 10.15 MHz	3	10	1-1/2 inches
14 to 21.5 MHz	2	5	1-1/2 inches
21 to 30 MHz	2	4	1 to 1-1/4 inches

The 1.8-to-4-MHz coil is wound with #22 wire, either DSC or enameled. Heavier insulated wire such as #18, #16, or even larger can be used on the other coils. L_1 is made of #14 insulated house-wiring wire and is close-wound over the ground end of L_2. If plug-in coil forms are not available, the bases of burned-out tubes can be used and made longer by means of cardboard or plastic tubing. The inductance of L_2 can be made smaller by spreading apart the turns of the coil. Squeezing the turns together increases the inductance of the coil.

L_2 connected in parallel with C_2 *must* tune to resonance at the frequency being used. This can be checked with a grid-dip meter. If none is available, one side of a neon bulb can be connected to the antenna post of the tuner. When rf from the transmitter is going into the tuner, the neon tube will glow when resonance at the frequency being used is attained by adjusting C_2. (Before the days of swr meters, "neon-tube tuning" was used to indicate rf voltage for endfeeding resonant-length antennas.) The diameter of the coil form can be different from those shown. If the diameter is greater, fewer turns on L_2 are needed. If the diameter is less, perhaps a turn or so more may be needed. The main consideration is that C_2 and L_2 must be of such values that they will tune to resonance at the frequency being used.

For the tapped coil, the coil form can be a piece of wooden dowel 1 to 1-1/2 inches in diameter that has been boiled in paraffin. Plastic, ceramic, or cardboard coil forms can also be used. The secondary (L_2) should have 35 turns tapped at 3, 5, 7, 9, 11, 13, 18, 25, 30, and 35 turns. If there are more positions on the switch, there could be more taps on the coil. The primary (L_1) should be close-wound over the ground end of L_2. Insulated wire #22 or larger should be used in winding L_2. Number 14 insulated house-wiring wire can be used for L_1.

The Lazy U Dipole

VE7BS's Lazy Z takes on a new bent.

Several years ago I described a sort of "Lazy Z" antenna in use on 160 meters. Pat Hawker G3VA commented on it in *Radio Communications*, a reader tried it on 40 meters and reported promising results, and Bill Orr mentioned it in his column in *Ham Radio*. Somewhere along the line it had become the "VE7BS Antenna," but by this time I had come to the conclusion that the "Lazy U" (described below) worked rather better.

The VE7BS was basically a half-wave dipole bent in the right places (see Fig. 1). The arrows show the direction of current flow at a given moment, and you can see that the two end sections are in phase with each other. Most of the radiation is from the center section where the current is higher, so the contribution of the end sections is not that great, and they are too close to each other to give any broadside gain. But this configuration does make it possible to have the main radiating portion at a relatively steep angle while preserving the useful bandwidth of a full-length dipole.

A straight sloping half-wave dipole 240 feet long suspended from a 100-foot-high support thinks of itself as a horizontal dipole 50 feet high and fires mostly straight up on 160. A bit of geometry or a scale drawing shows why—even if the wire were tight and straight, it would be only 24 degrees from the horizontal.

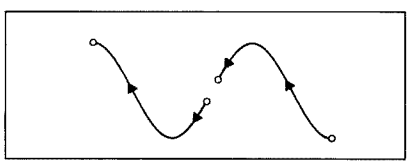

Fig. 1.

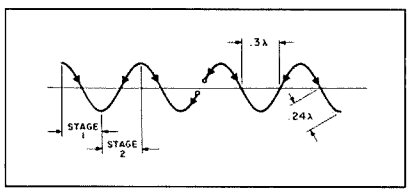

Fig. 2.

All this came to mind when W4KM brought to my attention an interesting item that appeared in *Radio* (published in the USSR), describing the "snake antenna" used by UY5AP for communication via satellites on 144 MHz (see Fig. 2). UY5AP's antenna is made with rigid coaxial cable, using the sheath as a fat conductor (3/8" or 1/2" copper pipe would be an ideal material to use for this kind of construction). It is described as a "seven-stage synphase" antenna, with a figure-8 pattern in the horizontal plane and a narrow lobe toward the horizon in the vertical plane. Bear in mind that this is on 144 MHz, so presumably the antenna is mounted several wavelengths above ground.

The dimensions given in *Radio* show that each stage is a half wave long, slightly shortened to allow for the diameter/length ratio, and the distance between each stage is a 5/16 wave.

In effect, then, we have seven close-spaced elements in phase as far as vertical polarization is concerned, but each stage is in antiphase to its neighbor as far as horizontal polarization is concerned. I came to this conclusion by playing with current-flow arrows, as illustrated in Fig. 3.

You can look upon it also as a pair of cross-polarized stacks with four elements copolarized and three others in quadrature with them. Maybe, with four in one direction and three in the other, this could be said to be elliptical? (See Fig. 4.)

This is all very interesting for the 2-meter satellite enthusiast, but for me VHF is an abstraction. To erect such an antenna for an HF band requires a rather long line of trees, but it doesn't *have* to be seven stages long, does it! After all, not all yagis have 60-foot booms, but there are lots of yagis around.

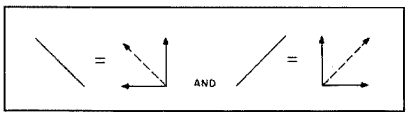

Fig. 3.

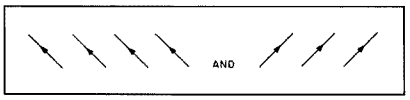

Fig. 4.

How about three stages? With a basically vertically polarized array it can be close to the ground without suffering ill effects, and for 40 meters a three-stage "snake" would be about 150 feet long and could be hung on supports 50 feet high. It would need only two such supports, because one end of the snake is close to the ground (see Fig. 5).

There are definite advantages to having an antenna that has cross-polarized elements. All signals coming via the ionosphere rotate on the way, and the degree of rotation is unpredictable. It is because of this rotation that you can get good signals (most of the time) on your horizontal antenna although the other fellow is using a vertical. But some of the QSB you suffer comes from the rotation of the signal, and if your antenna can respond to any polarization, you suffer less. I don't recall seeing anything about this antenna arrangement in the literature, although it seems impossible that Kraus and Sterba and Franklin and company could have overlooked it in the heyday of linear arrays for HF in the thirties.

The seven-stage VHF snake has a feedpoint impedance of 300 Ohms, so it is fed

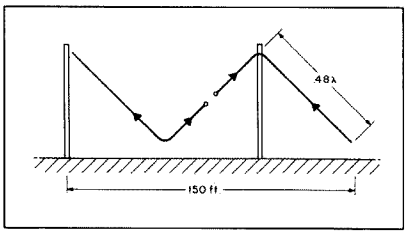

Fig. 5.

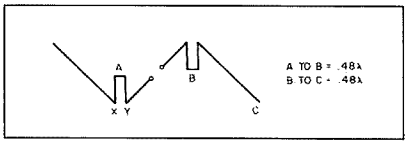

Fig. 6.

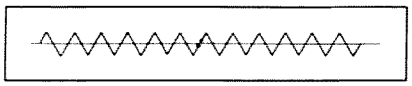

Fig. 7.

with 300-Ohm balanced feeder or with 75-Ohm coaxial cable through a 4:1 coaxial balun. In the three-stage HF version, the feedpoint impedance is between 100 and 125 Ohms. A quarter-wave section of 75-Ohm transmission line transforms nicely from 50-Ohm cable to the feedpoint impedance.

The wire is supported at the bends by insulators and a short piece of ABS tubing to keep the bend from being too sharp, so each "element" is 468/f long to allow for end effect. If available height or space is a bit short, there are some interesting possibilities in folding at the corners, as shown in Fig. 6. Points X and Y are at the same potential and sign, and so can be tied together without harming the resonance. But that's a complication.

A Japanese Snake

In 1984, a short item appeared in the IEEE literature[1] describing the results obtained from bending the wire of a dipole in zigzag fashion, but in this case at more frequent intervals than with the "synphase" just discussed. Starting with a length of wire a half wavelength long, it is bent as shown in Fig. 7 to make each zig or zag .0208 of a wavelength long (12 bends in each half of the dipole).

If the angle of each bend is made 130 degrees, the actual length of the antenna will be shortened by 10% and the antenna will be self-resonant with a feedpoint resistance of 65 Ohms and a negative reactance of about 50 Ohms. The patterns and the half-power bandwidth remain about the same as a straight half-wave dipole, and this stays true if the antenna is shortened further by decreasing the angle at each bend. What is more, the input resistance does not change radically.

For example, if you make the original wire .58 of a wavelength long and then compress it to .4 of a wavelength (20% shorter than a straight half wave), the input resistance is a little less than 50 Ohms, a direct match to RG-8 coax if you use a transmatch to compensate for any reactance that appears.

I suppose a stretched-out Slinky™ would work in a somewhat similar way, although the theory of the close-coiled Slinky is probably different. [*See "The Ramada Radiator" in this issue.—Ed.*] The possibilities of combining the shortening effect of the 24-bends-per-half-wave with the synphase effect of the one-bend-per-half-wave are endless. If you are interested, the basics of the shortening effect are covered in a 1982 IEEE publication[2].

The Lazy U

There are only two bends in the Lazy U variant of the half-wave dipole—see Fig. 8. You make the vertical portion as long as possible (some have been used on 160 meters with as little as 33 feet of vertical) and the top horizontal wire should be directly above (parallel to) the bottom wire. The bottom wire can

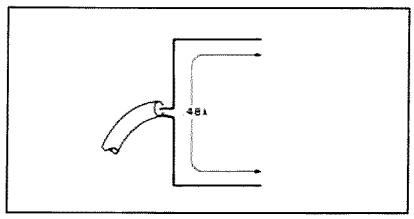

Fig. 8.

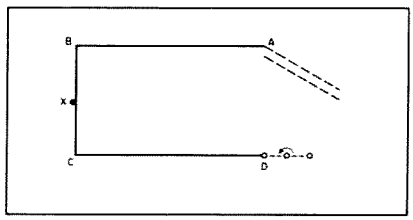

Fig. 9

be as close to the ground as practical convenience allows, but preferably at least six feet up; remember that there is a high rf potential at the end!

Radiation is effectively vertically polarized. Maximum current flows in the vertical portion, and experiments have shown that a displacement current flows between the upper wire and the lower (in effect, counterpoise) wire, creating a whole raft of phantom verticals.

It is much quieter than a vertical monopole on receive, and I have a special affection for it because it gave me my first African contact from VE7 on 160. (That particular antenna had about 90 feet of vertical, but one with 60 feet of vertical worked about the same.)

Bring the coax away horizontally for a few feet from either the side or the back of the U—a few turns of coax wound as a choke near the feedpoint will prevent antenna currents from running on the outside of the coax shield.

It is more or less a single-band antenna, but was derived from the multiband G8ON[3,4]—see Fig. 9. A to D is a half wavelength; on harmonic frequencies, X to D is an odd number of quarter wavelengths. X is the center of a half-wave section, the point of maximum current. AB and CD are equal, and AB is parallel to CD. CD is, in effect, a counterpoise, at least six feet above the ground. The dotted portion is a single-wire feeder—it could be open-wire zepp.

To use it on higher frequencies, you put suitable lengths of wire as extensions at D to create a current maximum at X (make the point X an odd number of quarter waves from the *far end*—point D).

A General Reminder

When you make a bend in a resonant antenna, make it as gradually as possible. A sharp corner tends to look something like a termination to the rf current arriving at it. Although the general idea is that you want the current to jump off some time in the direction of the other station, you also want it to recognize what frequency the antenna is designed for!

Have fun bending! ■

You've earned your Ham ticket.

Now What?

Now you're ready to get on the air but you're not sure about how to actually install that antenna; or how to solder a PL-259 connector; or how to properly ground your station; or identify unknown transistor leads; etc.

Here's the perfect companion for exploring the more practical aspects of the world's greatest hobby.

The new Heil Ham Radio Handbook was written by the 1982 Radio Amateur of the Year-Bob Heil, K9EID. Bob heads his own electronic manufacturing company and is respected world-wide for his sound systems, microphones and equalizers.

Bob's new book fills the gap that often makes the difference between sitting there watching the dial lights and actually making contacts that are the real joy of amateur radio.

This book doesn't stop at the intermediate level however; you'll find handy hints no matter how long you've been licensed, and unlike other publications you won't need a PhD in engineering to understand the material.

It's a money-saver too—you can make your own 5amp 12VDC power supply at 1/3 the cost, as shown in this handbook, from parts you may have on hand.

In fact, once you own and start using this Handbook you'll wonder why "somebody" didn't publish it sooner! And the sooner you send for it, the sooner you'll be enjoying more aspects of Amateur Radio . . . . Send $9.95 (plus $1.00 shipping) directly to:

The 75m Laid-Back Quad

Unable to build a 75m helix, N4VD settles for four 70-foot pine trees.

When I removed the February, 1985, issue of *73* from my mailbox, I was excited to see a picture of Ollie W1ZB standing beside a 20-meter helix. You see, I have a fetish about adapting VHF-style antennas to HF use. Ollie hit an experimental nerve in me, and I immediately went out looking for something between the size of a water tower and the Astrodome around which I could wind a 75-meter helix.

It must come as no surprise to anyone that I have yet to find a suitable cylindrical object that will serve as a winding form for such a corkscrew. Frustrated by the search, I retired to my deck one evening to grill hamburgers, drink 807s, and fondly recall past antenna successes. (Speaking of grilling hamburgers on the deck—it occurs to me that people used to cook in the house but go outside to use the bathroom. In today's society, we cook in the yard, then go inside to tend to our needs!)

I once built a 5/8-wavelength vertical for 75 meters. Boy, did it work like a champ! I even wrote an article about it for *73* ("The 75m DX Chaser Antenna," June, 1978) and had a lot of people write to tell me how they enjoyed building and using this unorthodox antenna.

Encouraged by that success, I set about constructing a 5-element, 75-meter log periodic antenna. A hundred dollars' worth of wire later, I had an antenna that performed so poorly that the only thing to receive my "CQ DX 75" was my neighbor's garage-door opener.

Not easily discouraged, I dug around in my 1939-vintage antenna handbook and came acoss (in, of all chapters, "Mobile Antennas") a "squalo" for 2-meter AM work. Said to be unidirectional, the squalo appeared to have possibilities for low-band work. Rotators for 75-meter arrays can, after all, get somewhat large and expensive if you don't happen to be the owner of a diesel engine shop.

Blessed with 70-foot-tall Carolina pine trees, I set about hoisting a 75-meter squalo up to the 60-foot level. It was 60 feet on each of the four sides of the square and fed with 50-Ohm coax. The swr was a reasonable 1.8:1. Signal reports were equally encouraging (nothing great, but at least as good as my inverted vee at the same height).

Proud of my work, I showed off the squalo to my father, WA4GBE. He studied it for a minute or so and then, displaying the wisdom of his years, said, "It's nothing but the driven element of a quad, laid on its back. Why don't you put a reflector element under it, and you can shoot 6 or 7 dB straight up into the sky?" It hurts when the ole block you're supposed to be a chip off of walks away laughing about 6 or 7 dB being hurled up into the clouds.

When he was safely out of sight, I regained my composure, did a quick calculation using a stick in the dirt, and determined that a reflector placed 0.2 wavelengths under the squalo would be located conveniently within arm's reach, only about 7 feet or so above the ground. 75-meter local signals (those that skip around in your own call district) are a product of atmospheric scatter. I deduced that an extra 6 or 7 dB of signal sent up might result in a good deal of it coming back down.

A reflector loop for a quad needs to be longer in length than the driven element. My pine trees were just far enough apart for the 60-foot-per-side driven element, making it difficult to come up with a way to fit a somewhat larger reflector into the same space. I considered loading coils, but it seemed much simpler just to get it as large as the space permitted and let a tuning stub make up the difference. A piece of TV twinlead was attached to the reflector and pulled along head high toward the center of the square.

Beginning 10 feet or so from its attachment to the reflector element, I began sticking a pin through the twinlead, thereby shorting together the two plastic-encased wires. My swr reading was up around 3.0:1 when I first checked it. Moving the pin a foot at a time, I finally found a point about 18 feet down the twinlead where the swr was back to a respectable level between 1.5:1 and 2.0:1.

Read on to the next paragraph—it's the old "tried it on the air and got nothing but 40 over 9 signal reports" testimonial!

The original squalo was roughly equal in performance to my inverted vee, making a test of the virtues of the "laid-back quad" fairly easy. Sure enough, on-the-air tests showed that a goodly portion of the theoretical 6 or 7 dB blasting off into the atmosphere was making its way back down to add to the QRM on 75 meters. It didn't do as much for my signal as when I added "Godzilla" (the old 4-1000A amplifier I drove with an SB-200) to the quad a year before, but it was good for one to two S-units over the inverted vee.

Not everyone has four conveniently located 70-foot pine trees with which to work. Even 45–50-foot supports will work well if the reflector is placed on the ground or slightly under the surface (known as a worm warmer). I once used this method at another QTH and found its performance equal to the above-ground version. I have talked about this antenna quite a bit on the air, and one day a fellow in Minnesota broke into a QSO to tell me he had tried my design but with a delta-loop arrangement since he had only three tall supports. According to him, it also was a real "signal pumper." His signal supported the claim.

Ollie, I'm still looking around for just the right cylindrical object to use as a winding form for my 75-meter helix. If you think of anything, let me know.■

Kit Corner: Build A Two-Tube Vintage Receiver

Excerpted with permission from Electronics Australia.

Of all the sets built by hobbyists since the 1920s, the allband one- or two-tube sets with plug-in coils were probably the most popular. Of these, the Reinartz circuit (Fig. 1) was undoubtedly the best known.

The basic circuit was devised by J. L. Reinartz and was published in the June, 1921, issue of *QST*. The set was of the "leaky-grid" regenerative detector type. It employed a spider-web coil with switched taps to cover various bands, and featured variable-capacitor control of the regeneration. It was this capacitive control that was the main distinguishing feature of the Reinartz circuit.

Previous methods of regeneration control included the "swinging reaction coil," the tuned-anode variometer, and other methods which used a fixed-reaction coil coupled to the tuning coil and which controlled the amount of reaction by varying the filament or anode voltage of the tube.

All of these methods worked (some more so than others) on the long and medium wavelengths, but when it came to operation on the shorter bands, the reaction control became very tricky. An unstable receiver was often the result. The Reinartz circuit quickly became popular mainly due to the smooth reaction control on the shorter wavelengths.

Simply explained, the reaction capacitor is in series with the reaction coil and is thus able to control the rf current through this coil. Adjustment of the capacitor provides precise control of the amount of positive feedback (regeneration) in the circuit.

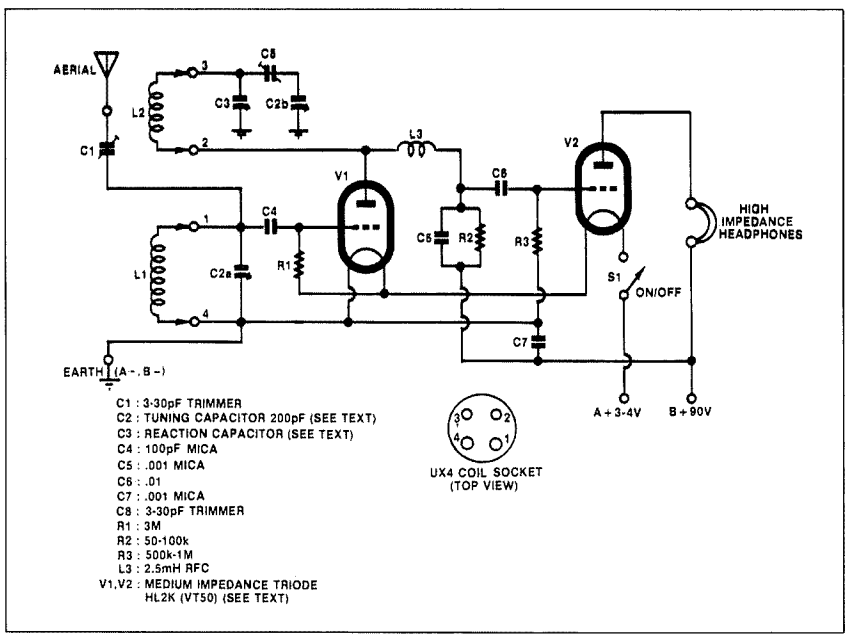

Fig. 1. Schematic diagram of the Reinartz all-wave receiver.

Circuit Details

Take a look at the circuit in Fig. 1. Signals from the aerial are coupled via C1 into the tuned circuit comprising L1 and C2A. Frequencies selected by the tuned circuit are detected by the grid of V1 which, together with C4 and R1, forms a leaky-grid detector. To improve the sensitivity of the detector to weak signals, grid-leak resistor R1 is connected to the positive side of V1's filament.

Regeneration is accomplished by the combination of L2 and C3, which feeds back some of the rf energy in such a way as to aid the original signal and bring about a great increase in gain and selectivity. The setting of C3 controls the amount of regeneration, with the optimum setting being just short of the point of oscillation (marked by a high-pitched howl).

L3 is an rf choke that prevents loading of the regeneration system by the following stage. It also operates in conjunction with bypass capacitor C5 to prevent rf currents from passing to the output stage. An rf choke in this position is always a feature of the Reinartz circuit.

Audio signals developed across V1's load resistor (R2) are coupled via C6 into the grid of V2, which drives the headphones.

It should be noted that the filaments are connected in series. This is done to provide an effective negative grid bias voltage for V2, obtained by virtue of the fact that both sides of V2's filament are positive with respect to the grid, which is at ground potential through R3.

C7 is an rf bypass capacitor across the B supply, and S1 switches power to the set by making or breaking the filament supply. The set requires an A battery of 3.4–5 volts at 100 mA, and a B battery of about 90 volts at 1.5 mA. Two heavy-duty D cells provide a suitable supply for the filaments, while a string of ten 9-V batteries will handle the B requirement.

The radio is built on a Meranti wood base, which has a "cove" routed edge. The tuning and reaction controls, the power switch, and the headphone jack are mounted on a front panel of gold-lettered black Bakelite™. A rear sub-panel, also of Bakelite, holds most of the other components, including the coil and tube sockets, and the terminals for the aerial and power supply connections.

". . . with correctly adjusted regeneration, the set performs as well as much larger sets do without regeneration."

On the Air

For best results, an outdoor aerial of from 10 to 30 meters long, mounted as high as possible, is desirable. However, quite respectable results can be achieved with a good indoor aerial in many locations.

When you are trying the set on any band for the first time, start with the reaction capacitor plates fully out of mesh and vary the setting of the tuning capacitor. You will probably hear some stations, though they will sound weak.

Now tune so that the station you want comes in as loudly as is possible. Then gradually turn the reaction capacitor so that the plates mesh. The loudness of the signal will increase as you do this, and if you now check the setting of the tuning capacitor you will find that it has shifted slightly. After a little practice, you will be able to tune the set very accurately in just a few seconds.

At the higher frequencies, the setting of both controls becomes more critical, and more skill is required to obtain the best results. You may find it easiest to make tuning a two-handed job. In any case, it is interesting to note that with correctly adjusted regeneration, the set performs as well as much larger sets do without regeneration.

Build the Kit

Dick Smith Electronics offers a complete kit for construction of the two-tube Reinartz receiver, including four hand-wound coils which cover 560 kHz to 19 MHz. Order kit number K-9000 ($99.95 plus $5 shipping) from Dick Smith Electronics, PO Box 2249, Redwood City CA 94064; (800)-332-5373.■

CoCo's Compu-Charger

K2OAW unearths an undocumented feature of the Color Computer—an automatic NiCd conditioner!

Using a Radio Shack Color Computer (CoCo), $3.00 worth of parts, and less than an hour of work, you can produce a circuit which will help you automatically test your NiCd batteries and keep them in tip-top shape.

Keeping NiCd batteries at their peak performance involves more than just charging them every night. It's nice to think that this always will make your hand-held radio ready to go the next day, but the fact is that NiCds require a periodic deep discharge to avoid a reduction in their charge capacity.

This is easy to do with a single cell—just put a load on it and wait until cell voltage drops to zero—but doing the same with multi-cell batteries can ruin them. The weak cells (which discharge first) continue to get the current from the good cells, but in a direction which reverses their cell voltage. This results in permanent damage.

Since usually we cannot disassemble a multi-cell battery into individual cells, this leaves the problem of how to discharge the battery by just the right amount—not too much, not too little. The usual rule of thumb is to monitor the battery voltage during discharge and disconnect the load when the total battery voltage drops to about 1.0 or 1.1 volts per cell. For example, a NiCd rated at 10.8 volts has nine cells; we can determine this by knowing that the rated output voltage of a single NiCd cell is 1.2 volts and 10.8 divided by 1.2 is 9. We should, therefore, stop discharging such a battery somewhere between 9.0 and 9.9 volts.

What we need, then, is a circuit which will monitor the battery voltage and disconnect the load as soon as the voltage drops to the required value. In addition, it might be useful if this circuit also could keep records on battery voltage during discharge and tell us how long it took to discharge the battery. This information could tell us what shape the battery is in. This is where a computer can become very useful, as it can completely automate a process which could take several hours, make sure to discharge the battery enough to be useful but prevent excessive discharge, and keep printed records as well.

As it turns out, the CoCo has some circuitry which makes it a natural for this job. It has a built-in analog-to-digital (A/D) converter which can be used to monitor the battery voltage and it has a relay which can be used to turn the load on and off. It has a video display which can be used to give us information about what it is doing, and it allows us to print a permanent record of battery data on a printer.

The A/D Converter

The analog-to-digital converter in the CoCo is actually part of the joystick circuitry. Unlike the joysticks on many other computers, which use switches and allow the computer to detect only the joystick direction, those on the CoCo use a pair of potentiometers which turn with the position of the stick. One pot monitors left-right movement while the other monitors movement forward and back. In addition to direction, the computer actually can determine how far the joystick has been moved.

Internally, the joystick potentiometers are connected as shown in Fig.1. Each joystick pot is connected between +5 volts and ground and outputs a voltage ranging from 0 volts at the bottom to +5 volts at the top. Since there are four pots (two in each joystick) and only one A/D converter, a 4-input multiplexer is in the middle. The multiplexer acts like a 4-pole selector switch which chooses which pot signal is fed to the A/D converter at any one time.

The A/D converter converts the input voltage into a 6-bit binary number. The largest 6-bit binary number is 111111, the equivalent to a decimal 63, so 0 volts corresponds to an A/D output of 0, while +5 volts corresponds to an output of 63.

The A/D output values can be sampled directly from Color Computer Basic with the JOYSTK function. For example,

A = JOYSTK(0)

would make A equal to the value obtained from the first potentiometer, and so on.

Since the A/D converter accepts a maximum input of +5 volts, and most hand-held radio batteries run between 7 and 15 volts, we need to reduce the applied voltage. This is most easily done with a simple voltage divider consisting of two resistors, as shown in Fig. 2.

The formula for calculating the voltage to the joystick input is: Joystick Voltage = Battery Voltage x Rb/(Ra + Rb). If only standard value resistors are used, it may not be possible to reduce the voltage to just the right amount. For example, with the resistors shown, this circuit cuts down the 15 volts of a battery to about 4.7 volts (depending on the exact resistor values). As it turns out, this is ideal because 15-volt batteries provide over 16 volts just after being fully charged. Assuming the resistors are exactly the rated values, this circuit will drop 16 volts down to exactly 5 volts, but the exact voltage drop will depend on the exact resistor values.

Knowing that a 16-volt input produces an output of 63 from the A/D converter, we need some

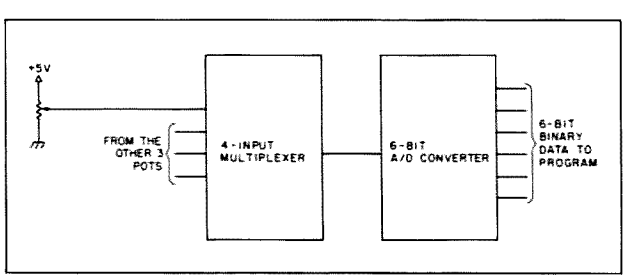

Fig. 1. Joystick connections in the CoCo.

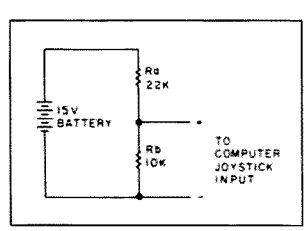

Fig. 2. Voltage divider for reducing battery voltage to a value within the range of the A/D.

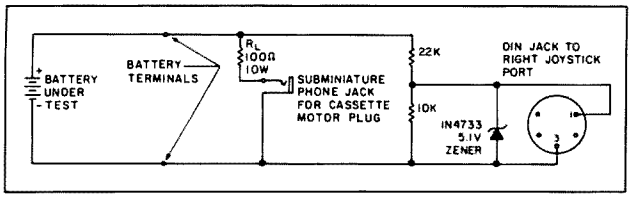

Fig. 3. Complete circuit.

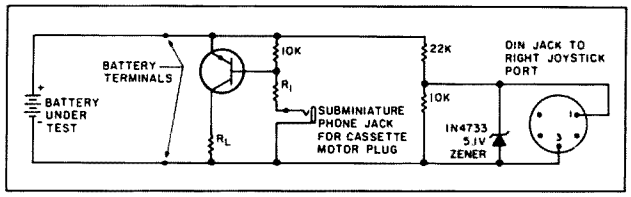

Fig. 4. Modified circuit for higher discharge current.

way of computing the voltage if we know the joystick A/D converter output. This is simply done by multiplying the A/D number by a constant, K, where K is found from the formula: K = Full-scale Voltage/63 = 16/63 = 0.254. Multiplying a reading of 63 by 0.254 gives us 16 volts.

As before, this is the theoretical formula, but in practice a slightly different value for K may be needed because of resistor errors. This may require a calibration procedure, described later. (For example, in my system, I use K = 0.26. The maximum voltage reading then becomes 63 x 0.26, or 16.38 volts.)

Since the A/D output is always an integer between 0 and 63, it changes only in steps of 1. Hence, the measured voltage changes in steps of K volts. For example, if I input 15 volts into the circuit in my system, my A/D converter outputs a value of 58. I then multiply this value by 0.26, which gives me a value of 15.08 volts instead of exactly 15 volts.

Notice that the resulting value is not entirely correct. This is due to the fact that a 6-bit A/D converter has only 64 different possible output values, ranging from 0 to 63. This splits the allowable voltage range into 64 possible values, and the A/D converter cannot measure any closer than that. In my particular unit, the minimum voltage reading is 0.26 times 0, or 0 volts. The next higher indication occurs when the A/D converter outputs a 1, which translates into a voltage of 0.26 times 1, or 0.26 volts. Any voltage below 0.26 volts will always read as 0; any voltage between 0.26 volts and 0.52 volts will always read as 0.26 volts, and so on. This means that any computer voltage measurement can always be off by as many as K volts.

Though this is not the world's greatest accuracy, it is certainly good enough to monitor the voltage of a battery to a reasonable accuracy.

The Load Relay

The second essential part needed for this application is a relay which can be used to control battery charge and discharge. In the case of the CoCo, such a relay is already built in—it's intended to turn a cassette-recorder motor on and off. The only disadvantage is that the relay's current-handling capacity is limited.

Although Radio Shack does not specify the rating of the cassette motor relay, my guess would be that it can handle 250 milliamperes safely, and perhaps as much as 500 mA. As long as we make sure not to exceed this current, there is no problem. The relay can be controlled quite easily from Basic with the two statements, MOTOR ON (to close the contacts) and MOTOR OFF (to open them).

The Full Circuit

When we put these two parts together, we get the circuit in Fig. 3. The circuit uses a 100-Ohm, 10-Watt, wire-wound resistor as the load resistor, R_L. To simplify connection to the computer's cassette motor relay, we put a subminiature phone jack (Radio Shack 274-292) in series with the resistor; this matched the subminiature plug at the end of the cassette cable.

The output of the voltage divider connects to the right joystick port through a DIN connector (Radio Shack 274-020), as shown in the diagram. An optional 5.1-volt zener diode (Radio Shack 276-565) protects the joystick input from accidental application of voltages above 5.1 volts or below zero.

I chose a 100-Ohm load resistor (Radio Shack 271-135) in order to limit the maximum current through the cassette-relay contacts. The maximum current can be found from Ohm's Law as Maximum Current = Battery Voltage/R_L. With a 15-volt battery, this current works out to 0.15 Amperes, or 150 milliamperes. This current will discharge a 450-mAh battery in approximately three hours.

Since discharge current depends on the battery voltage, batteries with a lower voltage will discharge more slowly. Table 1 gives figures for a few typical hand-held radio batteries.

This seems like a reasonable compromise between circuit simplicity and discharge time, but it is possible to lower the value of R_L as long as the relay current does not go past about 250 mA. (If you insist on discharging your battery faster, then you must modify the circuit by either adding a second relay or adding the transistor-switching circuit in Fig. 4. In this circuit, the PNP transistor must be large enough to handle the current without overheating—and should be mounted on a heat sink—and resistor R1 should have a value about 20 times the value of R_L to provide enough base current to the transistor to fully saturate it.)

The Program

The program to control the circuit can be as simple or as complex as you want it. For example, the program to discharge a 15-volt battery to 13 volts and then disconnect the load could be as simple as:

```
10 MOTOR ON
20 V = JOYSTK(0) * 0.26
30 IF V >= 13 THEN GOTO 20
40 MOTOR OFF
```

This program simply closes the motor relay and then loops in lines 20 and 30 as long as the battery voltage is 13 volts or more. Once the voltage drops below 13 volts, it goes to line 40 and shuts off the load by opening the motor relay. Though the above program works, the computer is capable of doing much more. The program listing shows the program I use.

When you start the program, the first screen is a menu listing the possible choices at that point. You may get the following menu at any time by pressing the H (Help) key:

```
BATTERY TEST PROGRAM
BY PETER A. STARK K2OAW
C—CALIBRATE
H—HELP
L—TURN LOAD ON
N—TURN LOAD OFF
P—PRINT ON PRINTER
S—START TEST
V—ADJUST VOLTAGE CUTOFF
```

Calibrate. As described earlier, the value of K may have to be adjusted for best accuracy. Although the program sets K equal to 0.26 (my value), another value may be more accurate for your particular combination of resistors. The Calibrate mode lets you adjust K for best results. Simply connect your battery to the circuit, connect an accurate meter across the battery, and press C. The program will display the following:

```
PRESENT CONVERSION CONSTANT
IS .26
ENTER MEASURED VOLTAGE;
(MINUS NUMBER TO QUIT):
```

You should now enter the actual measured battery voltage, and the new value of K will be displayed and placed into the program. (Once you calibrate the voltage reading this way, you may find it more convenient to put the correct value of K into line 70 of the program so you don't have to do the calibration each time you use your circuit.)

Help. You may press H at any time that the

Program listing.

program is running to get the menu, but if you remember the commands you need not get the menu—you can just type the required single-letter command at any time.

Load, No Load. These two commands simply operate the load relay. Each time you do so, the corresponding time will be displayed on the screen or printer.

Printing. P will give you a new menu:

PRINT MENU
P—PRESENT DATA
D—SAVED DATA
G—GRAPH SAVED DATA
ANYTHING ELSE—QUIT

All of these commands require a printer. C prints the current time and battery voltage; D and G print and graph, respectively, saved data (more on this later).

Start Test. This is the command which starts the battery test process. Pressing S will give you the following:

STARTING TEST
PRESENT VOLTAGE IS ...
PRESENT TIME = 00:00:00
HOW OFTEN DO YOU WANT DATA (IN MINUTES)?

At this point, you specify how often you

want the program to print or display the time and voltage. Then the program continues with

```
PRESENT MEASURED VOLTAGE IS...
PRESENT CUTOFF VOLTAGE IS 0
DO YOU WANT TO SPECIFY A NEW
  V—VOLTAGE CUTOFF
  P—PERCENTAGE CUTOFF
  L—LEAVE AS IS?
```

The present measured voltage is the battery voltage as currently measured with no load. The cutoff voltage is the minimum voltage you want the battery to discharge to before disconnecting the load resistor. This value is set in line 110 of the program and presently defaults to 0 volts, but you can change line 110 to default to any other value.

Alternatively, you can specify a new cutoff voltage at this point in one of two ways—as an actual voltage (with the V option) or as a percentage of rated voltage (with the P option). If you choose P, then the program will ask you for the nominal battery voltage and a percentage at which to cut off the load. For example, to discharge a 15-volt battery down to 90% of its rated voltage (i.e., 13.5 volts) you would enter 15 volts and 90 percent.

The final question will be REPORT ON TV OR PRINTER? You can answer with either TV (or just T) or PRINTER (or just P). If you have a printer, then the P option will print the time and voltage on the printer; the T option will display only on the TV screen.

Once you answer this final question, the program closes the load relay and starts to monitor the battery voltage. The top of the screen will display the present data like this:

```
TIME 00:00:00
VOLTAGE 15
LOAD ON
```

The time will increment each second and the battery voltage will be displayed continuously below it. At the same time, the bottom of the screen (and the printer, if you have selected it) will keep track of time and battery voltage. For example, Fig. 5 shows the printed display for a very weak 15-volt, 225-mAh Motorola HT-220 battery.

In addition to displaying or printing the time and voltage, the program also saves these in the T$ (time) and VO (voltage) arrays dimensioned in line 20. The D and G options in the print menu allow us to print or graph this data after the test is completed. The graph routine is set up for a 32-column printer (such as the Radio Shack TP-10), so it is very low resolution; you may want to remove the /2 in line 3270 to get a wider display on better printers. Fig. 6 simulates the graph for the data shown in Fig. 5; the vertical axis is voltage and the horizontal axis is time.

Calculating Battery Capacity

The clock time for the program is derived from the real-time clock of the CoCo as read by the TIMER function. It is quite accurate, although it may lose a few tenths of a second during long printouts. Since the time when the load is disconnected is printed, it is easy to determine how well the battery meets its specifications.

NiCd battery capacity is rated in mAh (milliampere hours) or Ah (ampere hours), the product of discharge current times discharge time. For example, a 1-Ah battery should last 1 hour at 1 Ampere, 2 hours at 1/2 Ampere, 1/2 hour at 2 Amperes, or 9 hours at 1/9 Ampere. In practice, though, there are two other factors which must also be considered.

```
NO LOAD VOLTAGE 15.6
LOAD ON AT 00:00:00
LOADED VOLTAGE 12.48
00:01:00          12.48
00:02:00          12.48
00:03:00          12.22
00:04:00          12.22
LOADED VOLTAGE 11.96
LOAD OFF AT 00:04:41
00:05:00          14.82
00:05:00          15.08
```

Fig. 5. Sample program printout.

First, what do we mean by a battery "lasting"? How low do we let its voltage drop before we give up on it? Most manufacturers let their batteries discharge down to either 1.1 or 1.0 volts per cell in determining cell capacity.

The second factor is the fact that the product of discharge time and discharge current varies with the rate of discharge. For example, a 1-Ah battery which lasts an hour at 1 Ampere load (which is called the "one-hour" discharge) may last slightly more than two hours at 1/2 Ampere, and slightly less than 1/2 hour at 2 Amperes.

Since discharging a battery at a lower current than the one-hour rate produces a larger time x current product, many manufacturers rate their batteries not in terms of a one-hour discharge, but in terms of two or even more hours. This complicates our calculations since we seldom know how any particular battery is supposed to be rated!

Nevertheless, assuming that the battery's mAh or Ah rating is constant results in a fairly small error. In particular, since our 100-Ohm load resistor results in discharge times of two or more hours in most cases, we should expect the product of discharge time and the discharge current to equal or exceed the battery rating—if the battery is in good shape, properly charged, and discharged down to the correct level of 1.0 or 1.1 volts per cell, depending on the manufacturer.

Hence, to calculate the actual capacity of the battery, set the discharge cutoff voltage to 1.0 or 1.1 volts per cell, let the program time the discharge, and then multiply the time in hours (convert minutes into fractions of hours) by the discharge current (which is approximately equal to the rated battery voltage divided by the value of R_L).

The only question is whether we should go down to 1.0 or 1.1 volts per cell. Although 1.0 volts per cell is used by manufacturers, in practice it might be a good idea to stop at 1.1 volts to avoid reverse-charging of weak cells. This will result in a lower apparent battery capacity, but the difference should not be more than about 10%.

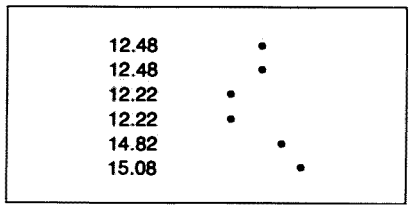

Fig. 6. Plot of data in Fig. 5.

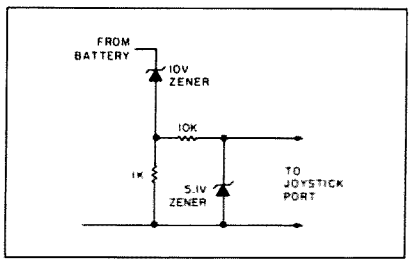

Fig. 7. Scale Expander Circuit.

Improvements

You can probably think of many ways of improving the circuit or program, but I have found it quite satisfactory for my purposes. Nevertheless, the circuit does have one disadvantage—the limited accuracy in measuring battery voltage caused by the limited resolution of the A/D converter. Although we could build a better A/D circuit, there is a much easier way of improving the resolution by a factor of two or three, and that is by expanding the scale. This involves a fairly simple change to the voltage-divider circuit as shown in Fig. 7.

In this circuit, the 10-volt zener does not conduct until the input voltage rises above 10 volts, and so the A/D converter indicates 0 output for any voltage below 10 volts. Once the battery voltage exceeds 10 volts, however, the diode subtracts 10 volts from the input and the A/D gets the battery voltage minus 10 volts. Hence, a 14-volt battery, for instance, sends only 4 volts to the A/D converter.

Now, instead of the A/D converter having to cover the entire range from 0 to 15 volts in its 63 steps, it has only to cover the range from 10 volts to 15 volts. Since it divides the range into 64 steps, the error is now just 5/64, or just about 0.8 volts. Note, though, that making such a change requires that the program also be changed to compute the actual voltage with a slightly different formula. Depending on the characteristics of the 10-volt zener diode, some additional program changes may be required to compensate for non-linearities in the voltage readout.

Conclusion

The circuit and program described here are handy applications of a small, inexpensive computer toward a very useful job. They provide a simple and cheap solution (assuming you already have the computer) to a problem which would require a fairly complex and expensive circuit if you wanted to do the same thing some other way. ■

"Making Life Easier With Magnets"

"Open House" in conjunction with the celebration of its 60th anniversary on September 21, from 10 a.m. to 8 p.m., at the North Park Village, 5801 N. Pulaski Avenue, Chicago. A special-event station will operate on 20 meters and 40 meters, SSB. For further information, call (312)-545-3622 or write to CARC, 5631 W. Irving Park Road, Chicago IL 60634.

SIERRA VISTA AZ
SEP 27

The Cochise ARA will hold a flea market on September 27 at the CARA Training Facility on Moson Road near Sierra Vista. For more information, write CARA, PO Box 1855, Sierra Vista AZ 85636.

SANTA FE NM
SEP 27–28

The Northern New Mexico ARC will hold its third annual hamfest on September 27 and 28 at Camp Stoney, eight miles east of Santa Fe, New Mexico. Exams will be given on Saturday; there will be a tailgate flea market on Sunday. Registration is $5 for adults, $2 for children under 12. Talk-in on 146.22/.82 or 146.52. For further information, send an SASE to Alan Hill N5BGC, 2020 Calle Perdiz, Santa Fe NM 87505.

ELMIRA NY
SEP 27

The Elmira Amateur Radio Association will present its 11th annual Elmira International Hamfest on September 27, from 6 a.m. to 5 p.m., at the Chemung County Fairgrounds. Tickets are available at the gate or in advance from Steve Zolkosky, 118 East 8th Street, Elmira Heights NY 14903.

GRAYSLAKE IL
SEP 27–28

The Chicago FM Club will hold Radio Expo 86 on September 27–28 at the Lake County Fairgrounds, Routes 120 and 45, in Grayslake, Illinois. Flea market opens at 6 a.m. and exhibits at 9 a.m. Tickets $4 in advance, $5 at the gate. Indoor flea-market tables $7.50 per day, reservations by September 10. Exams given. Talk-in on 146.16/.76. For more information, send an SASE to Radio Expo 86, Box 1532, Evanston IL 60204, or call (312)-582-6923.

HARVESTER MO
SEP 28

The St. Peters ARC will hold its second annual swapfest on September 28 at the Harvester Lions Club Park, Harvester, Missouri, about six miles south of St. Charles. $1 admission. Talk-in on 145.33. For more information, contact Joe Riordan KGØK, 2760 Hwy. 40-61, O'Fallon MO 63366.

GAINESVILLE GA
SEP 28

The Lanierland ARC will hold its Hamfest '86 on September 28 at the Holiday Inn in Gainesville, Georgia, from 8:30 a.m. to 3:30 p.m. Free admission. Exams given. Talk-in on 146.67/.07. For more information, write to George D. Floyd, Rte. 11, Box 661A, Gainesville GA 30501.

WELLESLEY MA
SEP 28

The Wellesley ARS will hold its annual outdoor flea market on September 28, from 9 a.m. to 2 p.m., in the parking lot of the Wellesley Senior High School, Rice Street, Wellesley, Massachusetts. Admission is $1 for buyers, $2 for sellers. Talk-in on 147.63/.03.

WATERBURY CT
SEP 28

The Waterbury (CT) ARC will sponsor a flea market on September 28, from 10 a.m. to 3 p.m., at the Waterbury State Technical College off I-84 in Waterbury, Connecticut. Admission is $2. Indoor spaces will be $10/table, tailgating $5. Dealers and sellers should contact Gary Firtick K1EB, 589 Hamilton Avenue, Watertown CT 06795, by September 15.

BOARDMAN OCTOBERFEST
SEP 28

The Mahoning Valley ARA will operate station W8QLY on September 28 from Boardman Park during the annual Rotary Octoberfest Celebration. Suggested frequencies are the phone sections of the 40- and 20-meter bands, and 145.01 packet. For a special QSL certificate, send an SASE to MVARA Octoberfest Station, PO Box 2950, Youngstown OH 44511.

Save Time, Work Safe with this Electrical Troubleshooter

The Tic-Tracer™ is a lightweight, rugged, non-contact instrument that sense AC voltage up to 3 inches away. Beeping faster as it approaches a live wire, it will let you:
- Check for live wires without touching them
- Find bad connections, broken wires, defective plugs and switches.
- Detect improper ground and polarity.
- Check fuse and breaker panels.
- Pinpoint electrical problems in live equipment

ALL WITHOUT TURNING OFF OR CONNECTING ANYTHING!

Try the Tic-Tracer for 30 days. If it isn't the handiest electrical tool you've ever owned, just return it for a prompt refund. GUARANTEED!

Made in USA
One-year warranty
Uses one 9v battery
Detects 25-1500 volts AC
$39.95 ea. postpaid
(two for $69.95)
Michigan residents add 4% sales tax

USING THE AO-10 PREDICTIONS

Apogee predictions for the month of September are provided for three sections of the United States: Washington, D.C.; Denver, Colorado; and Los Angeles, California. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

Crystal FT Filters

TRIPLE DISCOUNT SALE

The more filters you buy, the more you save! 10% Off on one, 20% on two, 30% on 3 *or more*. For example, one $60 filter costs $54; two $54 + 48; four $54 + 48 + 42 + 42. One $110 filter costs $99, two $88, etc. Figure each price group separately. For combos (matched pairs only) see prices below.

8.83 MHz 8-POLE FT FILTERS FOR KENWOOD - Reg. $60 ea.
Bandwidths: CW 250, 400 Hz; SSB 1.8, 2.1; AM 6.0 KHz. Suitable for all models from TS120 through TS940. TS440S introductory: Take $5 off sale price for two.

Filter Cascading Kits with FT Filter
TS430S - Discounted 2.1 filter *plus* $20 for amp board
TS820S - Discounted 2.1 filter *plus* $5 for parts

455 KHz 8-POLE FT FILTERS FOR KENWOOD - Reg. $110 ea.
Bandwidths available: CW 400 Hz; SSB 2.1 KHz. Suitable for R820, TS830, TS930, TS940. Matched Filter Pairs for Above Models - Reg. $170 ea. SSB: 2.1 KHz (455 and 8.83); CW: 400 Hz; (455 and 8.83). *Discounted Pairs*: one for $147, $279 for both.

3.395 MHz FILTERS FOR TS520, 511, R599 - Reg. $60 ea.
Bandwidths available: 250, 400 Hz; 1.8*, 2.1 KHz. *1.8 special - Take $10 off list, then discount!

Same deal for YAESU, DRAKE, ICOM, and HEATH filters!
Check your GREEN SHEET for List prices, or PHONE.

Antennas, antennas! If there's a subject that holds more fascination for amateurs, I have yet to hear of it. Everybody's got a favorite design, or configuration, or manufacturer. Horizontal polarization, vertical polarization, circular polarization, yagis, quagis, loops, J-poles, whips, phased arrays, stacked arrays. . . you could go on forever.

Certainly no topic arouses more controversy either, as one person's "tried-and-true" design is quickly debunked by others. There are those who do it all by the book, and there are those who burned their books a long time ago!

I'm going to touch on some assorted topics pertaining to VHF and UHF antennas that I think are relevant (based on conversations, correspondence, and other communications throughout the past year).

Gain. . .

Now there's a truly abused term. There are many types of gain—dB, dBi, forward, etc. *QST* has determined that gain measurements can be so misleading that they won't publish them in advertisements. It's not a bad idea—after all, when was the last time you saw an isotropic dipole?

How can you really measure the gain of your antenna array? I detailed a method using formulae from MIT some months back, but this is more useful at microwave frequencies since the distance between the two antennas under test must be 100 wavelengths (at 144 MHz, that's roughly 650 feet. Not too practical!).

The accepted way is to use calibrated test equipment and establish a standard for that particular test (or round of tests). One way might be to employ a simple dipole as a receiving antenna, fixed to a tripod. A low-level signal source is placed a certain distance away. This known source of energy is recorded at its source (such as another dipole or simple whip) and an rf millivoltmeter is used to record the output from the dipole. This number doesn't mean anything really; it's just a number to reference to.

Say the number is +3 dBm. This is logged, and the test dipole is replaced with the desired array, taking care to maintain the same distance from the signal source. The output of the source is checked for accuracy, and after alignment for peak signal readings, the rf millivoltmeter is again checked. In this hypothetical case, let's say the reading might be +9 dBm. So, what does it mean?

It means that your test antenna has a gain of 6 dB over the reference antenna. That's it, and nothing more! Of course, this could be influenced by any number of things, such as atmospheric moisture content (especially at UHF), interaction of nearby conductive objects, and even the stability and accuracy of the test signal source and the rf millivoltmeter! It's easy to see why so much controversy erupts over figures of gain. About the only thing you can do with some confidence is to measure comparable antennas from different manufacturers to see how they compare to each other, and this is exactly what happens at an antenna measuring contest. But you must have accurate, stable test equipment for the numbers to mean anything.

Assuming you can obtain such equipment, measuring your own and others' antennas (such as long-boom yagis) can be a worthwhile and educational experience, as well as fodder for endless arguments over a beer! In my own tests, I've employed stable low-level signal generators with a Boonton 902 rf millivoltmeter to make such measurements. In one case, I was able to verify within .25 dB a manufacturer's claim for forward gain. However, it required two identical antennas and some careful measurements!

Stacking

Disregarding the column I wrote on stacking a few months ago so unsatisfactorily, let me tackle the subject again. Stacking does provide many benefits, among which is increased forward gain. How much? The rule of thumb would appear to be 3 dB per array, based on pure math. Based on actual experience, it might be more like 2–3 dB per array.

Note that when I say "per array," I mean a geometrically equal array. If you start out with one yagi, adding a second should increase gain by the above figure. Since the process is a square-law function, however, you need to add two more yagis to your existing two yagis to increase gain by another 2–3 dB. Start with four, and you'll need to add another four to see that extra 2–3 dB.

What advantages are to be had? In addition to gain (again, a number meaning nothing unless you reference it to some known value), the capture area of the array, or aperture, increases geometrically. This is especially useful when engaged in extremely weak signal work, such as low-level tropospheric enhancement, scatter, and, of course, moonbounce. However, you may encounter some distortion of the sidelobe pattern, based on any individual yagi in the array.

Despite the fact that this is a geometric process, the horizontal spacing between yagis in an array may not equal the vertical spacing when optimum results are achieved. A classic example of this is the RIW 432–19 yagi, where many users of four-bay RIWs report that vertical spacing is on the order of 5-1/2 feet, but horizontal spacing is about 5 feet.

The angle of radiation will change, and this is more evident on 50- and 144-MHz arrays used in over-the-horizon modes such as Es and tropo. Is there an increase in the front-to-back ratio? In many cases, yes. In some cases, no. It's a grey area, for sure, and only experimentation will yield definitive results. As far as spacing goes, the rule of thumb has been one-half the boom length, for conventional arrays. In the case of some of the "long-boom" antennas seen recently, this number will change.

Your best bet is to consult the manufacturer's literature. I've found the KLM, Cushcraft, and Tonna literature to be quite accurate and helpful in this regard, especially in regards to stacking arrays. You'll also need to make up phasing lines or use power dividers (my favorite), which are not expensive and have typical losses of .05–.08 dB per unit. It goes without saying that your phasing lines and interconnecting cables should be high quality (I use Belden 8214 up to 432 MHz, and 9913 above that), as should your connectors. No sense trying to gain an extra 2.5 dB and losing most of it in a poorly made junction!

Impedance Matching

We can go all over the place on this one. Current matching schemes in use include gamma, T-match, balun, and folded dipole. The first is quite common to users of older Cushcraft antennas. Usually, a stub in series with a capacitor is used to make the connection to the driven element. This type of match is typically used with coaxial lines, and is somewhat of an effective match. In my experiments in the past, I've noticed a somewhat narrowband characteristic of this type of match.

T-matches are commonly employed by many manufacturers, among them Cushcraft and RIW. Here, two stubs either side of the center of the driven element are adjusted for best match. The common method is to screw these adjustments tight. RIW goes one step further and solders them directly, resulting in a somewhat corrosion-proof connection. T-match systems are more broadbanded than a gamma match.

Baluns are the method employed by KLM. Two types are used: coaxial and sleeve. The coaxial balun is no stranger to the HF operator, and the principle is the same at VHF, only low-loss Teflon™ cable is used for the connection. Coaxial baluns can suck up moisture over a period of time but are fairly reliable and provide a moderately broadbanded match. Sleeve baluns are in effect a section of transmission line and work the same way, but must be installed carefully to avoid moisture accumulation over a period of time. KLM usually provides drain holes in their baluns for this purpose.

The folded dipole provides a very good match. It's broadbanded and usually made from a loop of solid wire, so moisture isn't a problem. The connections can be soldered or screwed on. KLM uses folded dipoles on their 4-element, 144-MHz yagis, but by far the biggest user is Tonna Antennas, who employ them at 432 and 1296 MHz. This type of match is my own favorite at 144 MHz and above, since it is so simple and reliable.

One other type of match is the full-wave loop, used in loop yagis or quagis (quad loops). Loop yagis are very popular at 1296 and

above, as the phenomenon of water droplets hanging from conventional dipole-type elements degrades yagi performance. With a loop element, the water runs down to the mounting bracket for the element, out of harm's way.

With vertical antennas, the principles are the same. Instead of a gamma "clip" and tuning stub, we have a tuned coil with tap feeding the driven element—basically the same thing. The difference is that a vertical antenna is an unbalanced system, feeding a radiator against ground, whereas a yagi's driven element is balanced, using a dipole.

Some Weird Designs . . .

I've heard of some good ones. Back many years ago, one of my high school pals used a longwire with splendid results on 2 meters. Yep, it's possible and it works! Consider that a 60-foot longwire is almost ten wavelengths long and will have gain off the far end. In a pinch, you can use it.

Ground planes made from coathanger wire have got to be the favorite of any apartment dweller, college student, or operator short on cash. Here's how it's done: Cut four lengths of wire 19 inches long. Cut a fifth about 20 inches long and bend a loop in one end so the actual length is still 19 inches. Now grab hold of an old SO-239 chassis connector (or type-N female) and solder the loop piece to the center pin.

Obtain four solder or crimp lugs the same size as the coathanger wire. Bare about 1/4" with a file or sandpaper on one end of each wire and attach to the crimp lugs. Now fasten them securely to the four holes in the SO-239. Attach a piece of coax to the connector and run it to your rig. You can hang the loop wire from a string or other noninductive material out of harm's way. By the way, with the ground-plane elements at 90 degrees to the center whip, the impedance is about 37 Ohms, or a 1.5:1 mismatch. If you want to get closer to 50 Ohms, bend the ground-plane elements down to about 45 degrees, and you'll be there.

Want to obtain some gain in most directions without using a rotor? You can do it with four small yagis (such as KLM or Cushcraft 4-element, 144-MHz beams) mounted around a pipe, and a surplus Transco-type relay of the 4-pole, single-throw type. Then you need but one coax feedline to the shack and a five-wire control cable for the selector box. Presto! The world's fastest antenna rotor.

Want to build it cheap? Make a quagi! It's nothing more than a yagi with full-wave loop elements instead of dipole types. And, of course, a full-wave loop is easily matched—you drive it directly. One friend used such an antenna with four elements off his apartment balcony for several years with excellent results. It was made from soft-drawn aluminum wire and a PVC boom. Best of all, you obtain polarization in both horizontal and vertical planes, making it a versatile all-around beam.

How about using a circularly polarization antenna for terrestrial work? Why not? Another ham I know did this for years with outstanding results. In fact, he never worked the satellites at all, just Es and tropo and aurora (lots of it, too!) with a KLM 144-14C. He operated under the theory that over a long enough distance, both horizontally and vertically polarized waves degrade to a somewhat circularly polarized wave. It must have worked, for with 100 Watts and the KLM he worked some mighty fine DX throughout the South and Midwest!

I'll close with my personal favorite vertical antenna: the J-pole. Imagine the gamma match described earlier feeding a dipole-driven element. Now take that same stub and half the dipole, mount them vertically, feed with coax, and use the same sliding-stub technique to make a match. Presto! An antenna you can put just about anywhere—under an eave, against the house, in a closet, on top of your tower (or on the side), on a fence, even on your car! The J-pole is simplicity personified. It's cheap to buy or make and is very durable, not to mention being the ideal apartment or condo antenna for 50, 144, 220, and 432 MHz!

That's it for this month. Let's hear from you about your favorite antenna systems or schemes! Send along some photos if you can. Soon I'll try to touch on useful test equipment you can pick up cheaply that will come in handy around the shack, and give some observations on the 1986 CQ WW VHF WPX. Until then, see you Above and Beyond! ■

NEVER SAY DIE

from page 12

know diddley about computers. Oh, I knew the microcomputer just had to develop into a huge industry, but I didn't know how the fool thing worked or how to use it. So I set about learning computers. It wasn't long before I found I was becoming the teacher instead of the student. I kept at it and found my audiences growing. Along the way I was able to start and run some very successful computer magazines.

Amateur radio can be a key to success—if you'll let it. Persistence in radio means education. I hope you find it as exciting and as much fun learning as I do. It isn't work in its bad connotation. How much amateur radio do you know well enough to teach? Can you get up in front of your club and talk about OSCAR operating? How about packet? Slow scan?

There has been a need for years for a practical slow-scan unit for business. We've had the technology for this for well over ten years, yet I've just recently seen a practical unit marketed. Ham historians can go back through my editorials and see where I've suggested such a product several times.

With so few engineers coming out of our schools these days, there are all sorts of opportunities for sharp technicians. Sam Harris W1FZJ wasn't an engineer, but he used his amateur radio experience to become a world expert in microwaves. He's the chap who invented the first parametric amplifier and helped make Microwave Associates what they are today—Ma/com—the outfit giving the satellite business the shaft these days with their scrambling decoders.

Sam built the first parametric amplifier on six meters and I published the first article on it! Readers thought it must be an April Fool article, it was so implausible. His amateur radio work got Sam a nice spot with the big dish in Arecibo. Unfortunately, Sam smoked, so he's no longer with us. So did his wonderful wife, Helen W1HOY . . . gone too. We sure miss pioneers like Sam . . . not many left.

Call it education . . . call it doing your homework . . . it's one major separation between failures and successes. You have the best shot at getting to the big money when you start your own business, but the odds aren't very attractive. This is more because too many entrepreneurs start their businesses without doing their homework and find it's too late to learn all the things they should have known. 90% of all small businesses fail in the first five years. But darned few fail where the homework has been done.

One of these days I may be able to get schools to provide a practical business education. Did you see Rodney Dangerfield in "Back To School"? It was a fun picture, with one great bit where a pedantic college business professor is trying to teach the kids the theory of how to start a business. Dangerfield, a self-made millionaire, who has decided to get a college education and is starting in as a freshman, then points out many of the practical things you have to know to succeed, none of which have much to do with business theory. Great scene.

My advice to anyone interested in making it big with his own business is first to learn the pitfalls while working for someone else. It's dumb to learn with your own money . . . you'll run out . . . as 90% do. Heck, I worked for five years as editor of *CQ* before starting my own magazine. I'd probably still be making the publisher rich if he hadn't fired me. And he was doing very well indeed, by the way . . . pretty much retired on a big yacht. We didn't see him much. In today's dollarettes I'd estimate *CQ* was making over $1 million profit a year.

With communications starting to get into some serious growth, the need for new products and services is going to be almost unlimited. I believe the next really big technology explosion will be in communications . . . via satellites, fiber optics, cables, and microwaves. Our new-found computer power needs communications.

How many years now have I been pointing out the potential for optical data storage? It's finally beginning to emerge, as much from small firms as the giants. Until we get a re-writable optical storage system, I'd suggest someone work on a combination of optical and magnetic storage . . . the optical for high-density storage . . . perhaps a part of the disk for write-once (WORM) and a magnetic segment for indexing the data.

Getting back to education . . . if there's any real demand for theory articles in *73* I'll start a series. But if you'd rather rag-chew your spare time away, I'll just try to keep *73* fun to read and avoid straining your brain. It's up to you. I'm not talking electronic engineering, I'm just talking about your really understanding the theory you are supposed to know for an Extra-class license . . . and maybe a bit extra on digital circuits so you can cope with your ham rigs and their synthesizers.

Let me ask another question. How many technical magazines are you getting? Is the ARRL *Handbook* your ultimate reference manual?

I have a bone to pick with our schools. It's not a new one. If you've been reading anything much more than ham magazines, you know there's been a series of books published exposing the sad state of education in America. I get upset when I visit colleges and find much of their time is spent in remedial work . . . teaching things the kids should have learned in grammar and high school.

Sure, I think everyone should have an education in the arts . . . literature, art, music . . . maybe even food. I'm old enough so I had classes in all of these way before college. My idea of college is as a place to develop your skills for your business career. Artists can go to an art school . . . such as Pratt Institute. My mother went there and became an excellent artist. Musicians have the Eastman School of Music, for example. Engineers have MIT and RPI. But why should RPI have to teach music? That's ridiculous.

Should college graduates be so ill-equipped for a career that all they can do is drive a cab or empty wastebaskets. Yes, I've had college graduate wastebasket emptiers working for me.

One of my goals is to get colleges to teach not only the career material, but also to provide a practical business education to go with it. Then we'd see engineers who have some basic skills in business so they can grab managerial opportunities when they occur. The engineer who knows little about personnel management, accounting, investment banking, purchasing, marketing, salesmanship, public speaking, and so on, will usually avoid the better career opportunities that present themselves.

Take a subject such as advertising. As an expert in this, I'll let you in on a dirty secret. You'd be astounded at how few advertising professionals have any real background. Many of them are absolute frauds, making up for their lack of education with firmly held opinions. When you consider that virtually every firm needs advertising, it's amazing to me that there are so few courses available. I took an invaluable course at the Advertising Club of New York . . . one of the most valuable courses I've ever taken.

Almost anyone could become an expert in advertising in a few months just by reading a few books and taking a course. I'll bet you could run circles around 50% of the ad agencies in results, too . . . maybe 90%.

It's getting a bit difficult to become a computer expert now, but things are still wide open in most communications fields. I don't think there is a college teaching HF rf circuits anymore. They're teaching digital and microwaves. I'm not sure they're even teaching VHF and UHF circuit design.

Another frontier lies in getting stuff through the twisted pair. They're coming from 300 baud to 1200 . . . with 2400 moving up. But there are some sneaky ways of cramming 9600 baud on the lines. And we're hearing about 56,000! How much do you know about all this? If we can get that stuff through an ordinary phone line, how about putting it through a ham channel?

You've been reading a bit about spread-spectrum communications, but I'll bet you'd fall all over yourself if you were asked to explain it to your ham club. Well? Yes, I know it takes more effort than hoisting a cold 807. Maybe you find it more fun to get woozy with a few beers than to learn things. I've always found understanding something new to be exciting. I'll tell you what, the next time you see me at a hamfest or a club meeting, let's see if you can find a subject I'm unable to handle. I've got plenty of weak points . . . can you find 'em?

Another new technology that is working well for entrepreneurs is compact discs. You've probably read this is the fastest-growing consumer-electronic field in history. I've been visiting CD-only stores around the country. Most of 'em have been started on a shoestring, yet most of them have

gotten into the black in four or five months. Not bad for a retail operation. If you're into music, you might want to look into starting a CD-only store. It could turn into a chain.

There are a great many opportunities for people with an electronics background to start businesses. When microcomputers started I talked many hams into getting into the business. Some have done exceptionally well. Of course, if you're not using your interest in amateur radio as a way to build your electronic education, you're blowing a wonderful opportunity.

You might read through this issue of *73* and mark any parts that you don't really understand. Swallow your pride and corner a more technically apt ham and see if he can help you. He'll be flattered. Have I explained a fundamental fact of life recently? The more you get people to do for you, the more they'll like you. And the more you do for them, the more they'll hate you. So don't be shy about asking for help...it's the best way to make friends.

Speaking of which, I need your help. You may have noticed that *QST* is a tad fatter than *73*. This is a terrible situation—one which needs to be fixed as soon as possible. This is a situation where you can help. The formula is simple...the more advertising a magazine has, the more pages of articles it can publish...or club and operating news in the case of *QST*. A magazine generally attracts advertising in proportion to the number of readers it has. So if you can get some friends to subscribe to *73*, we'll have more advertising...more articles and a much fatter magazine. I'd love to have it up around 250 or 300 pages a month...but that's entirely up to you. Who do you know who should be reading *73*? Get after 'em.

If you have a job where unions are protecting your job and keeping you from progressing... I've had my share of that destructiveness...you're all set for long-term failure. You could hardly ask for a more secure grasp on failure. When I was in Chicago for the Consumer Electronics Show, I saw a *Chicago Tribune* union on strike—something to do with fighting work-saving plans by management. I suppose some bright college kid is trying to get them to shift from hand-set type to a Linotype machine. Tsk.

Even if you are completely settled in with failure in your own life...and have inoculated your kids with your same work ethic... how about getting your grandchildren off the treadmill? Would it really upset you if they became successful? Of course they're going to do as you do, not as you say. You're the role model, like it or not.

My grandfather helped Citgo get going back 70 years ago. My father started the first transatlantic airline. Neither did these things working 40-hour weeks, so I had excellent role models. I backed up this hard work ethic with education. When I got interested in amateur radio, I joined the school ham club and learned everything I could from the other kids.

It was my interest in amateur radio that pushed me into an engineering college instead of a liberal arts one. It was amateur radio that got me into the Navy radio-technician program, where I got a first-rate technical background in just a few months.

For years I learned, built, and experimented. I helped pioneer NBFM...then was an early sideband...one of the first in RTTY...one of the first in repeaters. My family gave me a good start. Are you giving your kids or your grandchildren as good a start?

There are some good books on success. I enjoyed the one by Ray Kroc, the builder of McDonalds. The Napolean Hill book, *Think and Grow Rich*, is in paperback. It's also available on video cassette, audio cassettes, and so on. If you aim at success, in the long run your chances of reaching this goal are much better than depending entirely on luck. Failure can be ensured by constantly pursuing the temporarily expedient.

Any questions?

BUILDING YOUR CLUB

The strength...and the salvation...of amateur radio lies in our radio clubs. Buying a subscription to *QST* is not going to save our hobby. For that matter, even buying a subscription to *73* isn't going to save it...though it will tell me you are interested in working with me to save it.

The secret to a successful ham club is the same as the secret to a successful magazine...it's gotta be fun. Unless an awful lot of hams...well over 5,000 in the last couple of months...have been lying to me at hamfests, they were going to be dropping *73* before long because it was no longer fun to read. Well, you'll lose your members if your club isn't fun. It's as simple as that.

But how in heck can you make a ham club fun for a bunch of weirdos, all with different interests? We don't have one hobby, we've got dozens of 'em...and obviously there's no way to please everyone. Maybe, maybe not. But let's look at the positive side of it and get a move on.

Your Club Newsletter

This is the medium that can make or break a club. As the publisher of *73* I get to see hundreds of club newsletters. Some of 'em are awfully good...some are pathetic. They don't have to be slick four-color publications, you know. The main purpose of the club newsletter is to get the members to come to the next meeting...so tell 'em what fun they're going to have when they come. Tell 'em what's on the program. If there's going to be a short pre-meeting technical session to teach feedline theory, urge them to brush up on their radio by coming early. You might get the club program chairman to knock out an enthusiastic piece explaining what s/he's got in store for the next meeting.

Have you considered a buck newsletter flea-market column? For $1 you can list four or five lines of gear you have for sale. This beats the devil out of the several-month wait for a classified ad in *QST* to hit. I don't know how much you shop the ham magazine classifieds, but my experience has been that 90% of the stuff is long gone by the time the magazine with the ad finally comes out. Once you're through with a piece of ham gear, don't put it up on a shelf and forget it...get it moving to someone who will keep it busy, someone who will get enjoyment out of it. Never mind that you'll probably waste the money you get for it on nonessentials such as food or clothes for the kids.

If you have a ham store in your area, you might start talking with the owner about running a couple pages of ads in your newsletter. It won't cost him much, but that, along with the classified bucks, can make the newsletter fly by itself. How much should you charge? Well, I'd suggest around 10 cents per reader per page. Thus, a two-page ad spread might

SWL's: Are You Plagued By

Phantom Signals?

Meet the Eliminator.

Don't let its small dimensions (4"x3"x2") fool you—the Grove **Minituner III** is a big weapon against images, intermod and phantom signals on your shortwave receiver!

This short wave/long wave pre-selector is designed to boost performance in the 100 kHz-30 MHz frequency range. If you own one of the popular general coverage communications receivers and are using an outside antenna, you NEED this extra measure of selectivity.

No power required. Simply connect between your receiver and antenna. Equipped for standard PL-259 connections. **Only $39** (free UPS shipping; $5 U.S. Mail/P.P.).

Ham Awards

Worked All States Award

by William V. R. Smith N6MQS

When you receive your first QSL in the mail, it's an exciting moment. It confirms contact with another ham. You begin to collect QSL cards and clear off wall space to display your cards.

Each day, you're excited about your new contacts. You start searching for new states. It doesn't take long until you want to contact all fifty.

Making contact with all fifty states is the first on-the-air goal for most radio amateurs. A high-power rig is not required; contact with all fifty states has been done by stations with only five Watts of power.

The first step is to get your paperwork organized. You'll need a list of all fifty states and a checklist for completed contacts which shows receipt of QSL cards. This list should be nearby when you're on the air. A U.S. map is useful to provide a visual aid, and each state can be circled as contact is made.

Making contact with each of the fifty states is only the first step. Most awards will require proof of contact. An operator in each state must send you a QSL card. There are three rules to follow to make certain you receive these cards: 1) You must send a QSL to get one, 2) Send a self-addressed, stamped envelope, and 3) Make contact with at least three stations in each state.

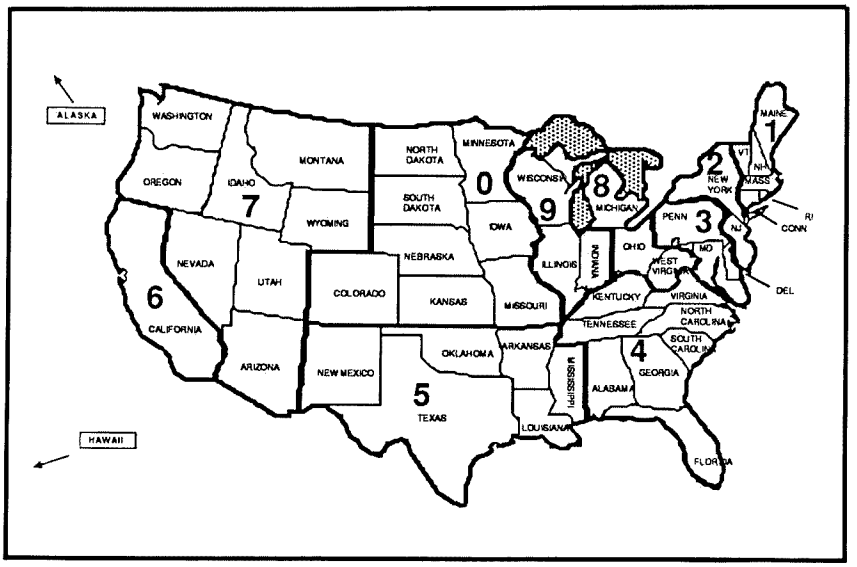
The attached WAS worksheet will simplify and organize your paperwork. It will also make the effort a lot more fun. Along with a list of all fifty states, the form contains room to log contact with three stations per state. Three contacts should insure receipt of at least one QSL card. Next to the state name is room for an 'X'. This will show that a card has been received and the state is complete.

Most "Work All States" awards have special endorsements. You may earn an endorsement for contacting all fifty state capitals, contact on one band, or contact only with YL operators. Most awards have several endorsements available: Review the award rules for a list of the endorsements. You can make photocopies of the worksheet and use a new sheet for each endorsement.

The U.S. map shown below will orient you to each state's location and its distance from your shack. The call sign areas are marked to help you identify a station's possible location from the call sign.

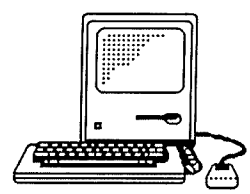
After you have completed the worksheet, it's time to apply for a "Work All States" award. Many nets and clubs have WAS awards available. The most popular WAS awards are presented by the American Radio Relay League (ARRL).

You may request an ARRL WAS award application by sending a self-addressed, stamped envelope to: ARRL WAS Award Manager • 225 Main Street • Newington CT 06111.



Along with the application, you'll receive a list of the many awards available and the special endorsements.

You will be required to fill out the application and sort your QSL cards alphabetically by state. The application and cards must then be mailed to the awards manager for verification. If you want the cards returned, you must enclose sufficent postage for their return (approximately two dollars).



When everything checks out, you will receive a handsome WAS award in the mail. The award is shipped in a protective package to save it from the postal machines. The award will include your WAS number. This can be placed on your QSL cards. You have earned the award, so show off a little!

It took me almost four months to work all fifty states. In the process, I received over two hundred QSL cards from fifty states and thirty-five countries. I'm now working on state capitals and DXCC.

73 to you and yours. Good luck with "WAS," and I hope you tune in next month. N6MQS

U.S. map showing fifty states with all ten call sign areas. Circle each state as QSL cards are received. Alaska is in the seventh call area. Hawaii is in the sixth call area.

The award form presented here was designed on an Apple Macintosh by N6MQS and printed on a Laser printer.

NK6K > PACKET

Harold Price NK6K
1211 Ford Avenue
Redondo Beach CA 90278

It struck me the other day that people not on packet wouldn't know where the title of this column came from. On packet, when you're just monitoring the channel, your TNC tells you who each packet came from, and who it's going to. If NK6K were sending packets to a station called PACKET, each packet would be displayed with NK6K>PACKET: in front of it. That's all there is to it!

PACKET IN OTHER LANDS

A more or less regular feature here for the months to come will be a review of worldwide packet activities. Hams in other countries have a different perspective, and operate under different rules. The questions I've asked packeteers in other countries are:

1) How many packet users are there?

2) What packet standard is in use?

3) What frequencies are in use?

4) Are there any regulatory restrictions on the use of packet?

If you don't see your country mentioned, feel free to send in the answers. This column was written on May 28, and most of the DX comments were received earlier in the month.

Japan

These comments were received on CompuServe from Toshi JG1REA:

"The exact number of packet users is unknown but growing fast. AX.25 is used in almost all cases. The UHF band is most commonly used; frequencies around Tokyo are 430.98, 431.0, 434.0, and 434.44 MHz (430.98 is the most active). The 1.2-GHz band is in use around Osaka. Many Americans are applying for the new reciprocal licenses. 7J1AAA (AH0A) operates a PBBS in Tokyo."

In conversations with other JA and U.S. hams, many have noted that packet growth in Japan has been slower than might have been expected given the high interest in computers there. One possible reason suggested was that the general crowding of the VHF and UHF bands made it hard for a new mode to "clear space." Also, since the TNCs and software were developed in the United States, initial Japanese participation was limited to those who could work well in English. Early difficulties with TNC software in passing 8-bit data made it hard to send the various Japanese extended character sets through the TNCs. These problems have been largely overcome, and the packet transponder aboard the JAS-1 satellite should spur further interest.

South Africa

These comments were received on Telemail from Hans van de Groenendaal ZS6AKV, President of Southern African AMSAT:

"Packet radio first came to South Africa when Gordon Hardman ZS1FE/KE3D returned to Cape Town after the launch of OSCAR 10. He brought two TAPR Beta units which were extensively demonstrated at a SA AMSAT Satellite Communication Conference.

"After the launch of TNC-1 by TAPR, some 30 units found their way to the Johannesburg/Pretoria area. This was further boosted by TNC-2 and various models of the GLB units. Now the AEA Pakratt and PK-80 are further stimulating the packet revolution.

"In 1985 the first digipeater, ZS6LAN, was set up in the Johannesburg area, followed by a packet-radio bulletin board in Pretoria. Unfortunately, earlier this year lightning struck and blew up the bulletin board system. It was expected that a new system using the WA7MBL software and IBM-compatible hardware would become operational in June/July 1986.

"One of the first TAPR Beta systems is now used at the Johannesburg Amateur Radio Center.

"The total number of packet-radio stations in South Africa is estimated to be around 100, with the major activity centered around Johannesburg/Pretoria, Durban, Port Elizabeth, and Cape Town.

"The general operating frequency is 144.675 MHz.

"Plans for this year include setting up a digipeater system to connect Durban and Johannesburg/Pretoria."

United Kingdom

The U.K. has gotten off to a slow start mainly due to regulatory issues. Repeaters are tightly controlled by the Department of Trade and Industry and by the RSGB; currently, digipeaters are not allowed. The following comments came via the Uo-11 Digital Communications Experiment from Jeff Ward G0/K8KA, a temporary resident of the U.K. who is working on an advanced degree at the University of Surrey. He says that this is his understanding of the situation. The matter is still under review by the RSGB and the DTI, and neither body has made any firm policy statements on the matter yet.

"Activity: approximately 200 stations are equipped for AX.25. Centers of activity are in the London area, the Southwest (Devon and Cornwall), and East Anglia. The local activity is on 2 meters, with no generally agreed upon frequency at this time.

"In the near future, RSGB is expecting permission from the Department of Trade and Industry for a number of packet-radio repeaters on 2 meters. The frequencies 144.650 and 145.275 will be occupied by this network until the end of 1987, when UHF or microwave frequencies for packet will be identified. The 2-meter frequencies are being used in the short term, because most of the people interested in getting on packet radio will already have 2-meter capability, and the RSGB does not wish to force people to buy both packet-radio equipment and new rf equipment to enter the packet network. The 2-meter band is very crowded in IARU Region 1, however, and so, as packet activity increases, the network MUST move to higher frequencies.

"The current working definition of 'packet-radio repeater' is any store-and-forward device, which includes digipeaters, PBBS systems, and any higher level network relay device. Digipeating by individual stations is not legal, and will not be legal in the early stages of packet-radio implementation in the U.K. All repeaters in the U.K. must be separately licensed. One-to-many messages (bulletins, newsletters, messages to ALL) come under the definition of broadcasting, and will not be allowed initially, either. In the second phase of regulatory investigation, it is hoped that the DTI will allow limited bulletin-type messaging (at least by official bodies already generating bulletins) and reconsider the third-party-traffic clauses. RSGB hopes that amateur-to-amateur-via-amateur traffic will be exempt from third-party clauses.

"The DTI blessing for packet repeaters is expected to be granted quite soon, and while it usually takes several months to get a repeater license in the U.K., a few packet-radio repeater licenses may be sped through the process, resulting in an operational network by midsummer."

The initial close regulation may work to the advantage of network planners in England. The U.S. network has grown in a slightly topsy-turvy manner as various methods were tried, expanded, or discarded. The U.K. hams now have that base of experience to work with, and they can start out with a second-generation system, taking the best of what is available

DIN Connector		Mini-Plug	Sub-Mini-Plug
pin 1	(use center of shielded cable) (put 2.2-uF tant. in series)	middle sleeve	
pin 3	(same cable as above-use) (shield . . .)	big (top) sleeve (tip is unused)	
pin 4	(second piece of shield cable-use center)		tip
pin 2	(big center lug-use shield from pin 4 cable)		sleeve

Table 1. Wiring a Kenwood TH-21/31/41 for packet operation with a TNC-2/200/2A.

and developing new systems without having to maintain backwards compatibility with older installed systems.

Network Statistics

We need some. Most of our current metrics on network performance are subjective, i.e., based on perceptions of performance, as in "The path up north was really useless last night." While user happiness is one of the prime goals when tuning a network, best results are gained with a more quantitative measurement. If you're looking for something to do, how about implementing some network analysis tools? We're so bad off now, almost anything you'd do would be a vast improvement. Here are some questions we need answers to:

- What is the average size of a packet?
- What is the average number of digipeater calls in a packet?
- Which callsigns originate the most packets?
- Which callsigns receive the most packets?
- How many unique callsigns appear on the frequency each interval?
- What is the average number of retries?
- What is the average number of simultaneous active connections on the frequency?
- Which digipeaters receive the most use?
- For mailboxes, what is the split between local messages and messages destined for other systems? What is the split between personal messages and to-ALL messages? What is the distribution of file sizes normally seen on the network?

All of this needs to be broken out by various time intervals and plotted by time of day/week/month, etc. Each local area will be different.

The performance of the next round of networking software can be affected by all of these parameters. The network will also be more complex and have even more "tuning knobs." If we can't tell how well the network is running at time T, how will we know if we've improved it at time T1?

Just to put you in the numbers mood, here's a statistic we do have. The *NEPRA PacketEar*, the newsletter of the New England Packet Radio Association, keeps track of total message counts for 24 BBS systems in the New England area using figures gathered by WØRLI. They report a total of 5171 messages handled in the period 4/12/86 through 4/28/86. For this number, a message is counted each time it passes through a BBS, so if one message were forwarded 13 times in New England, the count would be increased by 13. While there were not 5171 unique messages, the BBS systems did pass messages 5171 times between them. How many unique messages were there? Someone should write a program to figure that out.

Speaking of things to do, here is a list of other things that haven't been done, or things that have been done but haven't been written up, which might as well be the same thing.

- SSTV through packet—I know that some graphics files have been sent, but has anybody taken a camera and digitizer, hooked them up to packet, and let them rip?
- Voice through packet—There are fancy ways to do this, and then there are brute force methods. If someone comes up with a simple audio-to-bits and back-again circuit, I'll send your audio file up to UoSAT-OSCAR-11, we'll get it downloaded and played out in England, and you'll be in the record books for the first amateur transatlantic store-and-forward voice-gram. You can get a lot of "Hello, OM" into 96K of memory. Even with a simple 6-kHz, 8-bit A-to-D, you can get 16 seconds of message sent. Squeeze the file, and you'd get 25 to 30 seconds. Get fancy, and get more. Any takers?
- Packet above 440 MHz—TAPR and AMSAT ran packet between their booths at Dayton one year on a pair of loaned ICOM 1.2-GHz rigs. Is anyone doing it on a regular basis outside of Japan? Anyone taken a pair of 10-GHz Gunnplexers and pushed packets through them?
- Network map standard—There are several different "network maps" around, from the pin-and-yarn map seen at conventions to the multi-K-byte EASTNET map. All of them are hard to read, and all are hard to update and integrate. Anyone have a good idea how to print a network map?
- Network user database—I know I want to send mail to VE3GYQ, but I don't know which BBS he gets his mail from. Short of calling him up and asking, which takes all the fun out of it, how do I find out? If he has a BBS, how do I know which BBS routes mail to him? I've seen several attempts to start local, regional, and national directories, and there are at least three ongoing in southern California now. Anyone have an idea on how to make the updating job easy, and how to share data across local network boundaries?

We've got a lot to do, and if the trend of the age of the average ham increasing one year per year continues, we don't have much time left to do it in. (On the other hand, counting users would get easier every year!)

Kenwood TH-21

Several people have asked for information on how to hook up a TNC to the Kenwood shirt-pocket radios. I put out a call for help, and got the information from the Radio Amateur Telecommunications Society (RATS). Their address is 206 North Vivyen Street, Bergenfield NJ 07621, should you be in their area and want to join. Table 1 gives the details.

That's it for this month.■

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

ASPIRATIONS

When you're young, you have aspirations.

Most young men and women have very normal goals in life. Some kids want to work hard and become captains of industry, others dedicate their lives to science, and a few look for an easy way out and pledge their lives to politics.

As a teenager, I also had goals, one of which included becoming a repeater owner.

Ah, repeater ownership—there's the life. A repeater of your own. No one telling you that you're hogging the machine, reminding you to leave a pause between transmissions, or hounding you for membership dues. You're the boss, number one, numero uno, head honcho. The Big Cheese.

When you're 22, as I was in 1976, those are powerful thoughts. When you're 22, a dyed-in-the-wool ham, a B student at a commuter college on Long Island, and someone with no aim in life, repeater ownership is nothing less than an aphrodisiac.

So one fine spring evening in 1976 I asked my friend, Jon WA2MJK, if he was interested in launching a repeater.

"A repeater?" he said, looking at me as If I had asked him to join me on a DXpedition to Venus. "They cost money!"

Jon always was sort of practical.

"Sure they cost money," I replied. "But if we build one from a kit, we can save a lot of dough." I then hauled out a copy of *73*, and showed Jon an ad from a company in Binghamton, New York, that sold repeater kits.

Jon looked at the ad, then raised his eyes toward me in a most skeptical fashion. "John," he said, "the only kit you ever built was a Heathkit Sixer and, if I recall correctly, that never worked right because you left six-inch-long leads on all of the resistors.

"I know," I replied, "but that was 1969. I'm an Advanced now. I know better."

So the discussion continued for the rest of the evening, with Jon pointing out the headaches of repeater ownership while I spun a tale of glory and power. In the end I won. I had Jon wrapped around my little finger.

The next several weeks passed quickly. There was equipment to build, frequencies to acquire, FCC applications to fill out, antennas to erect, and spirits to sag.

The first assault on our hopes came from the ARRL frequency coordinator, who we cornered at a meeting of the local repeater council. The coordinator responded to our request for a 2-meter channel pair with the same bemused attitude a loan shark exudes when asked for extra time on a loan. First he laughed, then his nostrils flared in a most nasty way.

"A 2-meter pair? I got loads of them. They're in my pockets. Look, see," he said, turning his trouser pockets inside out.

Feeling a length of RG-8/U tighten around my gut, I croaked out, "How about 450?" figuring that UHF was better than nothing.

"Look, kid, you want a repeater,

go use one. New York is the repeater capital of the western world. We got repeaters here that haven't had a human voice on them since Maxim invented coffee. We're talking about an underutilized resource, pal."

The repeater coordinator was tiffed. Jon started sniffling. I felt sick.

Then, I don't know what it was. Pity, I think. Jon and I were looking fairly pathetic, which was a typical state of affairs for the two of us.

The coordinator glowered, raised his eyes heavenward, and said: "Look, guys. I know you fellas are never going to get a machine up anyway, and I got a pair of 220 frequencies. Some club up in Westchester was supposed to use 'em, but they never got their act together, either. They're yours for a year. Get a machine up and they're yours forever. In a year, maybe that Westchester bunch will be ready to go."

Two-twenty. Yoweee. We were in business.

"The next step," said Jon, alternately sucking down a beer and puffing on a Salem in the mature manner that only a recent graduate of Youngstown State University could muster, "is to build the machine." He was right.

So we ordered the repeater kit from that company in beautiful Binghamton, New York. Another *73* ad had won another customer. The kit, when it arrived, was beautiful.

"Look here! It's a chassis!" shouted Jon, his eyes aglow, as his fingers clawed into the massive crate.

"To hell with the chassis," I yelled. "I got the reset button!"

Immediately, we began dividing up the parts packs. I made the assignments.

"The receiver's for you, the transmitter's for me, the carrier-operated relay's for you, the IDer's for me." Already the power was rushing to my head.

The work went quickly, the repairs went slowly.

"Worst damn soldering job I've ever seen," said the tech in Binghamton on our second visit to that fair city on the shores of the Susquehanna. (The first trip back to Binghamton had failed to sort out our repeater's problems. It's funny how little cold solder joints can have such a major effect at 220 MHz.)

"Heh-heh," I chuckled, in my best Edward Arnold-style insincere laugh. "You know how little brothers are," referring to my blessedly innocent sibling, Jim WB2LWJ. "Last time I let my damn kid brother work on a circuit for me," I said.

Some folks have claimed I have a bit of the pathological liar in me. Nevertheless, with the now-repaired machine, I was the chief control operator of what I knew would become the Big Apple's premier 220 repeater.

Of course, being the chief control operator of a New York 220 repeater, at least in the 1970s, was a bit like being king of the North Pole—your kingdom had plenty of land coverage, but few subjects. But that fact was still unknown to two innocent hams.

Standing in my parents' basement, a Station Master perched on the roof, Jon and I jointly flicked the Master Control Switch. A red pilot light glowed, a hiss spilled out of the repeater's speaker, and the transmitter tripped. I expertly adjusted the squelch knob until the hiss disappeared and the transmitter unkeyed. But as I was doing this, the IDer kicked in: Dit dah dah, dit dah dit, dit dit.... WR2APG was open to the world. A salty tear rolled down my pudgy little cheek. A tingle went up my spine. I had reached the pinnacle. I had peaked. The only way left was down.

The next few weeks went slowly. "Silently" might be a better word. Precious few souls visited WR2APG, the pride of Glendale. Occasionally, a passing mobiler would stumble across the frequency, give a call, and then, after getting a 25-minute greeting speech from Jon, rapidly move on.

For six long weeks, we had three regular users: Jon, myself, and Pierre, a retired prison guard who lived in Manhattan. Pierre was the only other person we knew who actually owned a 220 rig. We used to steal him away from the NBC repeater for QSOs.

At night, I would lie in bed listening to the COR thump, the sound grumbling up through the floor. Occasionally, I would hear Jon's muffled voice say, "WA2MJK listening, WR2APG." Sometimes, I would hear Jon kerchunk the machine. I knew it was Jon because Pierre went to bed early. On the whole, generally speaking, it was pathetic.

Things got worse. A storm knocked the Station Master over. We fixed it. A taxi company caused intermod. We fixed them. Then Jon, who was in advertising, got a job offer from a midwestern firm that was a direct-mail record manufacturer. "The 101 Collected Hits of Allen Ludden" was their big hit. You may have seen the commercial on TV. The company also repackaged classic movies with modern personalities. Remember "Oy! A Yankee Doodle Dandy!" starring Myron T. Cohan?

Without Jon's 50-percent financial support, WR2APG couldn't go on. After all, a $10 a week allowance can only carry a repeater so far. New York's premier unused 220 repeater was heading for bankruptcy.

So we sold our beloved machine to a group of guys who already operated a wildly successful 2-meter repeater. They said they were going to place our baby, built with our own hands and rebuilt by the tech from Binghamton, on top of the Empire State Building. Show-offs, right?

Well, they did it. Within two-and-a-half weeks the guys from 2 meters were up there running autopatches, crosslinking over to 10 meters, setting 220 DX records, holding Dean Martin celebrity roasts for ARRL officials, and having a grand time. I would listen at night, holding my HT on my lap. The IDer sounded so familiar, the callsign so foreign. In 1979, short for cash, I sold my 220 rig. I haven't been back on the band since.

Not so long ago, Jon moved back to New York. The record company went belly-up after it diversified by marketing Rod Carew snowshoes. The infamous Mild Winter of 1985 caused the firm's frozen assets to melt.

Sometimes, when the moon is full and our heads are empty, we reminisce about old WR2APG. The times we almost had, the people we didn't meet. The power I wanted to wield.

One recent night, Jon recalled an incident of 220 repeater lore.

"Remember the time you hollered at the FCC representative because he announced they were discontinuing 'WR' prefixes?" Jon said.

"That was at the '77 ARRL New England Division Convention up in Hartford, wasn't it?" I replied.

"Indeed," said Jon. "If that fellow was a member of the radio police, he would have taken you from Hartford to Danbury and thrown you in the federal pen."

"I got kind of attached to WR2APG," I said.

"Bad manners. Bad form," said Jon.

"Aw, damn," said I.

"That was the mildest epithet you used," said Jon.

The other day, I asked Jon if he was interested in starting a computer bulletin board.■

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

My faithful readers will have noticed that last month's *73* was devoted to the phenomenon known as packet. I have covered packet in various aspects in the past year or so, and today I have a different way of looking at the subject. Let's have a look at some packets you all have sent me, in the mail, of course! (Well, somebody has to be an individual!)

Several times in the past few years I have mentioned a RTTY program for the Apple computers that I knew only as the "Galfo" program, and I have repeatedly asked for information on it from all of you. Well, this month, several of you have dropped me a bit of information. Al Sines WA3QGA in Laurel, Maryland, tells me that he has the version of the program supplied by AEA (Advanced Electronics Applications) with his CP-1 interface. He relates that it works with all versions of the Apple II series up to, but not including, the Apple lie.

John Donohue AB7M of Seattle adds a little more information. He tells us that the program was written by Dr. H. Christopher Galfo WB4JMD in 1978. It requires Integer Basic, and to run it on other than the Apple II requires an Integer card or a RAM card in slot 1 so that the Integer Basic may be loaded from disk.

Operation on Baudot (Murray), ASCII, and CW is available. Bau-

dot and ASCII speeds are from 32 to 300 baud; CW can be run between 2 and 125 words per minute. CW receiving speed is adjustable by the program from 1/3 to 3 times the selected speed.

AEA, Inc. (PO Box C-2160, Lynnwood WA 98036) has this program available as "CP-1/Apple-1." The price, according to John, is $29.95. He says that the program is furnished on a DOS-3.3 disk together with a connecting cable to run between AEA's CP-1 modem and the Apple II's 16-pin DIP game port.

John adds that operation of the Galfo program is easy enough, although a newcomer to RTTY may have to study the documentation from time to time until he is at ease with all the features. The only problem he has had with it is that the function which provides for storing a message for later transmission seems to be limited to about 250 bytes.

Thanks for the information, fellows, and I am sure that Apple owners appreciate the guidance.

Okay, folks, now listen up. Earl Morris N8ERO passes along the news that as of this writing (end of May) he has a Model 15 Teletype machine offer to anyone who would like it. Assuming it is still available, contact him at 3200 Washington, Midland MI 48640.

Newcomers are always welcome to RTTY Loop, and I have a letter here from Gary Halbe N3EMY in Willowgrove, Pennsylvania. Gary says that he is a "relatively new ham and very excited but confused at the same time. There seem to be many, many directions in which to go, and it's quite difficult with limited time and finances to do it all. However, I do enjoy the digital communications aspect quite a bit. I have enjoyed computers for some time. In fact, that is partially what got me into amateur radio. Anyway, not to digress too much, I also read your monthly RTTY Loop column and find it very interesting and informative even though I do not have a RTTY setup at this time. I do hope to set up a RTTY station shortly, though, and at work they were discarding what appeared to be a fairly new Teletype machine. As I have several computers in the house, I took the opportunity to get a free printer. As it turns out, this machine did not print what it was supposed to be printing. I searched around for model numbers, etc., and found several bits of info.... The manufacturer is Siemens. I phoned them to see if they could shed any light on why I could not properly connect this to my computers. The person I spoke with informed me that the reason was my computers were using ASCII and the Teletype was using Baudot. Now my question to you is did I find myself an inexpensive piece of gear I can use on RTTY, and if so, where can I find more info on what I need for interfacing, programming, etc.? Just a little more info which may be helpful in your determination is that this Teletype has the tape punch and reader. I believe it was hooked up to a phone line, and it has three wires, send (+), rec (−), and gnd.

"I wish I could give you more info such as a model number or whatever, but at the moment I can't. If the info I did give is enough, please let me know what to do with it and/or how to do it. Hopefully, it will all work out and sometime in the near future I will be on the air. If it is useless and I have some piece of worthless space-eater, let me know so I can lug it out of the shack and have some room again."

Hoo boy, Gary! Siemens is a German manufacturer that has built quite a variety of devices, from the teleprinter you describe to the electrocardiograph machine in my office. Even a picture would be helpful to try to figure out just what you have. Even better, if there are any RTTY-o-active hams in Gary's vicinity, why not give him a call and see if a hands-on session doesn't do the trick. Let me know what happens, Gary.

Timex/Sinclair folks, your turn! Don Cain NJ6Z of Los Angeles has used the NARP program for the Timex/Sinclair ZX-81 for receive, and feels it worked well. He passes along the information that NARP also uses a terminal unit designed by the author of the software, Cliff Nunnery NU4V of Fort Walton Beach, Florida. Sounds good, Don, and thanks for the information.

Maryland recognizes hams.

On the other hand, Gregory McKenna VE2AGY of Chateaugay, New York, owns a Timex 1000 computer and would like to put his machine on RTTY, too! Anybody? I have searched my files, such as they are, and have turned up nothing on the 1000. (I know, somebody is going to send me an old column where I mentioned the thing. I never said I was organized!) Anyway, let me hear from you if you are using a Timex 1000 on RTTY, and I will publish the information for all to benefit.

Phillip H. Creasy, Jr. KC3FG of Hermitage, Pennsylvania, says that he would be interested in a RTTY program for the CoCo that would access disk to send, receive, or keyboard buffer for storage, and spool off to a printer at 1200 baud for autostart RTTY. At least, Phil! Why stop there? Seriously, though, the wish list is well received. Now, I am not normally one to spread rumors, but I have it from several reasonably reliable sources that there are a few CoCo RTTY—as well as other modes—programs soon to be announced—right here, if we're lucky! So, stay tuned. I will not hold onto this information one issue longer than necessary.

Winner of the "voice from the past" award for this month is Tom Kennedy K8TK of Clark Lake, Michigan. Tom is another one interested in the ancient 6800 microprocessor which, he says, "still appears on college campuses and seems to be one of the best processors to 'cut your teeth on.'" Thanks for the other good words in your letter, and a copy of the reprint list is on its way to you in the mail. That reprint list remains available for any of you, of course, for a self-addressed, stamped envelope sent to the address at the head of this column. I have put together a bunch of material from the early days of this column, updated and revised, which seemed to interest many of you. Feel free to send for the list and look it over. It'll only cost you a stamp—the list, that is.

I have mentioned a few items of interest to CoCo owners in the past, and here's another. Bob "Whiffle" Rosen, the ham whose Spectrum Projects cater to the needs of the CoCo computerist, advises me that he will offer a new keyboard to readers of RTTY Loop at less than half his usual price. The new keyboard, the type being supplied on new CoCos, drops right into all CoCo IIs, "F" boards, and TDP-100s. Normally selling for $39.95, it is being offered for $14.95. An adapter for D or E boards is also available, for $9.95. Add $3 shipping and handling for each keyboard, and send orders to Bob at PO Box 21272, Woodhaven New York 11421—be sure to ask for the RTTY Loop special. By the way, Bob adds that if you get a few folks together, six or more keyboards ordered at one time will drop the price to just ten bucks apiece! Thanks, Bob.

Another topic we have touched upon here in the past has been WEFAX. This facsimile transmission, frequently heard along the HF spectrum, is a potent source of information with weather maps, slow-scan TV signals, and the like. Well, just finding the signals has been a problem, a problem which Joerg Klingenfuss has addressed once again. His *Guide To Facsimile Stations* has just been published, and quite a work it is! Frequencies from VLF to UHF are covered, with more callsigns, pictures of test patterns, and assorted advice than you are likely to find in any other single source. There are even schedules of 94 FAX stations on 340 frequencies. This valuable tome sells for DM30 [2.27 Deutschmarks = $1 as of early June] and is available direct from Klingenfuss Publications, Hagenloher Str. 14, D-7400 Tuebingen, Federal Republic of Germany. Be sure to mention RTTY Loop if you write. Who knows, maybe one day I will work out a stateside distribution arrangement with them (Hoeren Sie, Joerg?).

In a couple of months, we will be looking at some of the items you all have found useful for RTTY in the annual shopping guide. How

about some nominations, folks? Drop me a line, either on paper or via E-mail, with your vote for the more useful RTTY items available, and, if you like, the klunker of the year. Try to get the information to me as soon as possible for inclusion in this year's guide.

Still very little curiosity out there about Green Keys! What if I tell you that they were NOT named for Wayne?

One closing note, the photo this month is of our new Maryland Amateur Radio Operator license plates. Aren't they nice? They even *say* "Amateur Radio Operator" on them, reflectorized, and everything! I just thought that those of you who still may be fighting for callsign tags might like to see these new designs. If anyone from our State Motor Vehicle Administration happens to be a ham reading this column, thanks!

More fascinating stuff on tap, with my promise to look at at least one thing that nobody else would look at. Of course, I look forward to your comments, as always, via the postal service or CompuServe (ppn 75036,2501), but now you can add Delphi to the list, username MARCWA3AJR. As long as I can afford the connect fees, I will try to stay on-line now and then.

Until next month, then, that's it for RTTY Loop!■

Saugus CA 91350

COORDINATION FEES or HOW MUCH AM I OFFERED FOR .16/.76?

Hams may soon find themselves paying for repeater coordination! The FCC says that no specific rules exist to preclude repeater frequency coordinators or councils from charging fees for coordinating, moving, or maintaining a repeater's coordinated status.

This information came to light in early May as the result of a meeting between opposing factions of Alabama repeater owners and FCC field personnel. The meeting was ostensibly to determine what two-meter band plan Alabama would follow and who would oversee future Alabama coordination efforts. Some of those in attendance favored the continuance of the existing Alabama Repeater Council plan, with its mandated imposition of the Pacific Northwest 20-kHz band plan in the 146–148-MHz subband allocation. Others said that 20 kHz was not working; that it caused interference to systems on 15-kHz centers in neighboring states. They said that the Alabama Repeater Council had acted unilaterally by forcing them onto 20 kHz. They were demanding a return to 15-kHz channel spacing and the dissolution of the new alliance with the CVRA Southeastern Repeater Association even though the CVRA had previously stated it wanted no part of Alabama until it straightened things out.

CVRA founder Wayne Williams K4MOB had told me that the CVRA was not going to walk in and attempt to solve the problems of another area, and he did not want his organization accused of pillaging another state simply to make itself even larger. Regardless of what some Alabama repeater owners were demanding, the CVRA maintained a hands-off, wait-and-see position.

And so it was to happen at this meeting in Birmingham on May 10 that officials from the FCC's Atlanta field office would be asked one key question: Was it possible for whomever would wind up coordinating repeaters in Alabama to collect a fee to offset the cost of performing frequency coordination and maintaining an accurate data base?

At that time, the FCC people could find no specific regulation that precluded the collection of fees. Wasn't there anything in the Part 97 rules to cover this? How about the regulations covering pecuniary interest on the part of hams, preventing them from receiving compensation for voluntary services rendered? Well, to make it brief, subsequent conversations between this reporter and various Washington FCC officers also failed to find anything specific to keep such fees from being imposed and collected by coordinators. Also, under the present regulations, there is no maximum limit on what such a fee might be.

While the regulations covering the VEC program that permit collection of a specific amount to reimburse VECs and VEs for their out-of-pocket expenses might be applicable here, unlike the VEC program, the costs involved in frequency coordination vary greatly between geographic regions. This is because of such variables as the number of hams served, the demand for repeaters on a given band, and the spectrum still available for new systems. Deriving a fee schedule for coordination and maintenance of coordination data for each geographic region might prove to be impossible.

For example, a single coordinator in a sparsely populated region such as Idaho might have negligible operating costs because he has relatively few repeaters to be concerned with, a fairly small amateur population, and plenty of room for new systems on every band from 10 meters up to light! On the other hand, the same job for a major coordination council serving a state like New York, Illinois, Texas, or California might find its costs running into the hundreds or even thousands of dollars to perform the same individual task for each new repeater or change demanded by an existing system.

If you set a single national fee based on the average costs to all councils combined, there will be some very wealthy coordinators in the hinterlands with little to do, while their city cousins are fighting to make ends meet. Or at least they'll be making that claim, since permitting fees to be collected for coordinating ham repeaters does immediately commercialize amateur relay operation one more step.

The Analysis
